The archaeological excavations of 2019/20 at Købmagergade in the inner city of Copenhagen have revealed structures from the 12th to 19th c. AD. The area changed from a peripheral location in the early settlement to workshops and housing for the local nobility. Especially wooden latrines, trenches filled with manure from cattle and horse stables and pits from the 16th century have clearly been filled and recut several times indicating limited space available, but also that the laws not to build latrines, cesspits etc. too close to the city’s streets and people’s houses were upheld. Perhaps due to these laws we also have an example of a well, being reused as either a latrine or cesspit filled with faeces. Written sources describe that waste and manure was collected and sold to regional farmers as fertilizer for their fields. This suggests regulations from the authorities. Several on-going scientific analyses, such as archaeobiology and ITRAX-scanning, shall help further our knowledge of the workings of medieval waste management. First results show that sorting of waste clearly took place, as latrines and waste pits include almost no archaeological finds such as pottery or bones but were used for human faeces as well as organic household and workshop waste. Earlier excavations in Copenhagen suggested that animal bones and larger scoriae were used as pavement for the medieval town ´s streets. The medieval recycling and management of waste seem to be more complex than previously thought.

4 PEACEFUL USE OF DEFENSIVE STRUCTURES - SPACE RECYCLING AND ITS SOCIAL AND ECOLOGICAL ASPECTS ON THE EXAMPLE OF WROCŁAW, POLAND

**Abstract author(s):** Legut-Pintal, Maria (Institute of Archaeology - University of Wroclaw)

**Abstract format:** Oral

A system of walls and moats around the locational city of Wrocław, Silesia, was built relatively early (from around 1240 to 1291). At the same time, the city expanded to the south and east and new external defensive walls and moats were built. From around the half of the 14th century, internal strengthening lost its military function and became a desirable investment area for City Council and townspeople. Until the beginning of the early modern period, a large part of the old fortifications gained new functions and blended into the building structure of the city. Analysis of historical and iconographic sources along with archaeological research conducted from the second half of the 20th century made it possible to trace the forms of land development in place of the former fortifications. A variety of transformations of the use of space from becoming prestigious to degradation has been identified. A defensive wall could be used as parts of new buildings or demolished and used as a building material. Interwalls (Zwinger) were places of craft production, gardens or were built up. The moat transformed into a source of water, a place for removing impurities and a source of energy. The development of the space after the former fortifications has become an opportunity to correct the city’s spatial arrangement by, among other things, creating closed settlements for groups of people engaged in onerous activities, unwanted in the very center of the city. Despite the physical and legal unification, a mental boundary between the area inside and outside the inner walls has remained. With this article, we want to discuss the spatial and social aspects of these transformations as well as their impact on the urban environment.

5 FOOD, FODDER AND... CONSTRUCTION MATERIAL! A CONSIDERATION OF RYE (SECALE CEREALE L.) AS A RESOURCE IN TRADITIONAL HALF-TIMBERED HOUSE CONSTRUCTION

**Abstract author(s):** Filatova, Sofia - Kirleis, Wiebke (Institute for Prehistoric and Protohistoric Archaeology, Kiel University) - Holtgrewe Stukenbrock, Eva (Max Planck Institute for Evolutionary Biology, Plön; Botanical institute, Kiel University) - Krause-Kyora, Ben (Institute of Clinical Molecular Biology, Kiel University) - Claaßen, Benjamin (Max Planck Institute for Evolutionary Biology, Plön) - Torres, Guillermo (Institute of Clinical Molecular Biology, Kiel University)

**Abstract format:** Oral

The tradition of the construction of half-timbered houses goes back to the Middle Ages and Early Modern period and today these houses are praised as symbols of cultural heritage within many cities in Germany. Hidden behind walls, between floors, and under the rooftops of these historical buildings, are numerous remains of plants that were once used for the purpose of temper of construction materials and isolation of the houses. For our project, “Genetic variation in ancestral crops” within the ROOTS Cluster of Excellence (Kiel University), we focus on the study of plant remains from so-called Wellerhölzer. These parts of half-timbered houses were originally located between floors and consisted of wooden planks wrapped by cereal straw and covered by clay/loam. In many cases the assemblages of straw represent harvests of single crops, typically those of rye (*Secale cereale* L.), and thus form excellent archives for the reconstruction of past agricultural practice and ecology of cultivated fields. In addition, Wellerhölzer provide an important insight into the use of so-called by-products, or threshing remains, of harvests within traditional construction of buildings and thus exemplify the use of the entire harvest (i.e. grains, chaff, culms and weeds) as a resource.

In this contribution, we present the results of archaeobotanical analyses of plant remains that were retrieved from Wellerhölzer from various towns in Germany, dating between the Middle Ages and Early Modern period. We aim to define the types of assemblages that are represented in the Wellerhölzer and to compare them across the different towns and time periods. The results will be used to reconstruct important characteristics of rye cultivation and to shed light on the value of rye straw as a resource in house construction.

6 NEO-ASSYRIAN AGROPASTORAL AND FUEL RESOURCE USE AND REUSE AT ZIYARET TEPE, SOUTHEASTERN ANATOLIA

**Abstract author(s):** Proctor, Lucas (University of Connecticut) - Rosenzweig, Melissa (Northwestern University) - Greenfield, Tina (St. Thomas More College, University of Saskatchewan) - Matney, Timothy (University of Akron)

**Abstract format:** Oral

As a multiregional hegemonic state, the Neo-Assyrian Empire mobilized and redistributed commodities throughout its territory, often by extracting resources from its margins, through tax or tribute, and transferring them to the imperial core. However, at the local scale, inhabitants of these provincial areas would have had to balance these requirements against local subsistence needs and sustainable maintenance of the local resource-scape. In this study, we consider how local agropastoral production and fuel harvesting formed a circular economy embedded in the wider land use practices of Assyrian urban centers by combining evidence from excavation with archaeobotanical and zooarchaeological specialist analyses at Ziyaret Tepe (Upper Tigris Valley, southeastern Anatolia). Ziyaret Tepe, identified as ancient Tušhan, was an important urban center and provincial capital on the northern frontier of the empire. Textual accounts have suggested that the region controlled by Tušhan was an important source of timber and surplus grain and livestock for the Assyrian heartland.

Previous work has documented a mixed agropastoral economy at Ziyaret that included large, imperial-managed herds and grain agriculture. Evidence suggests that several products and byproducts of these activities were recycled and transformed for reuse within the subsistence economy, including the use of grain and/or straw as fodder to support herds, and animal dung used as fertilizer and/or fuel. However, analyses of fuel remain from the site also indicate that the Assyrians may have been increasingly degrading the local vegetation surrounding the site through tree clearance and overgrazing at the same time. Together, the data from Ziyaret Tepe paint a complex picture of resource exploitation and management in which agropastoral activities are linked and reused at the local and landscape scale.

7 DUCKS AND GEESE IN ROMAN BRITAIN: A CASE STUDY FROM LONDON DISCUSSING THE USE OF WILD RESOURCES IN URBAN SETTINGS

**Abstract author(s):** Poland, Ged (Independent)

**Abstract format:** Oral

The use of wild animal food resources in urban centres is often assumed to be the result of elites procuring speciality food, is often not discussed at all, or cannot be discussed because of methodological constraints in identification. However, wild animal food resources may have presented a seasonal, and perhaps vital, opportunity for all members of society to add variety to the diet, vital protein, and fat.

One aspect of the use of wild meat in urban centres that is particularly rarely discussed is the use of wild ducks and geese. This is despite the frequent recovery of their bones from archaeological sites in Europe. This is largely because until recently there were few options for identifying whether a bone belonged to a wild individual or not, not to say what wild species the bone came from. Following the development of reliable identification criteria using traditional morphometrics and multivariate statistics it is now pos-

sible to reliably identify most duck and goose species in north-west Europe. This paper will discuss the use of wild ducks and geese within an urban setting using sites from Roman London as a case study, comparing the results with sites in other parts of Britain, namely Fishbourne Palace, Caister-on-Sea, and York. It will be discussed whether the assumption that wild meat usually means the actions of elites acquiring speciality food is reasonable, or if it is possible that other groups in urban societies had food procurement networks that mean they can acquire seasonally available sources of meat to augment diets.

8 **URBAN STRATEGIES AND RESOURCE USE: MARINE AND TERRESTRIAL FOOD RESOURCES IN THE SETTLEMENTS OF MEDIEVAL ZANZIBAR**

**Abstract author(s):** Lisowski, Mik - Alexander, Michelle (BioArCh, University of York) - Fitton, Tom - Wynne-Jones, Stephanie (Department of Archaeology, University of York)

**Abstract format:** Oral

The Swahili coast of East Africa is known for its monumental stone towns that developed during the peak of Swahili culture in the second millennium CE. Research interest in the growth of Swahili urban centres has increased in recent decades, but much has to be done to investigate the use of local resources underpinning that urban development. In this paper, we focus on the exploitation of food resources at two Swahili coastal settlements from the Zanzibar archipelago: Unguja Ukuu and Tumbatu. Previous studies suggest that reliance on marine, and domestic and wild land animals at Swahili settlements might have varied; and that strategies often changed over time. To explore this across sites of two chronological periods, we use conventional and – previously scarcely used in this region – biomolecular zooarchaeology, including carbon and nitrogen stable isotope analysis. Results at Unguja Ukuu indicate that during the peak of occupation (7th-10th centuries) the exploitation of marine fauna was extensive, and domesticate and wild mammals seemed to play a smaller role. Excavations across the settlement revealed spatial and chronological changes in the patterns of marine resource use. The town at Tumbatu (11th-15th centuries), in the north of the Zanzibar archipelago, displays a different pattern, much more dependent on land resources. Data on economy, diet, and resource use at those two settlements broadens our understanding of the development of Swahili urbanism.

9 **CRAFT NETWORKS AND SCALAR ECONOMIES IN THE SOUTHERN AFRICAN REGION (900-1600 CE)**

**Abstract author(s):** Moffett, Abigail (University of East Anglia)

**Abstract format:** Oral

Studies of crafting within past societies, that assess interrelated aspects of the craft production system such as the identity of artisans, the organisational and social relations of their production and the distribution and consumption of crafts, provide important an avenue for developing critical, multi-scalar perspectives on past economies and societies. Research conducted at the site of Shankare (900-1300 CE), located near Lolwe mine, the earliest dated copper mine in southern Africa, aimed to explore the ways in which crafters were embedded within regional economic networks and processes. Crafting at Shankare was characterised by a dynamic domestic economy, with copper production taking place in domestic contexts alongside ceramic production and textile spinning indicative of time and labour scheduling and multi-crafting. Exchange and consumption patterns reveal that crafters were networked into a regional economy that facilitated access to locally produced and imported items and technologies. Together with evidence of crafting practices at urban centres such as Mapungubwe (1200-1300 CE) and Great Zimbabwe (1000-1700 CE), this research highlights the variable ways in which craft processes were embedded within the political economy.

282 **SYSTEMIC APPROACHES TO AGRICULTURAL AND LAND USE CHANGE IN PREHISTORIC SOCIETIES. PART 2**

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Antolin, Ferran (Integrative Prehistory and Archaeological Science - IPNA/IPAS, University of Basel; Department of Natural Sciences, German Archaeological Institute) - Whitehouse, Nicki (Archaeology, School of Humanities, University of Glasgow; School of Geography, Earth and Environmental Sciences, Plymouth University)

**Format:** Regular session

Farming practices are embedded within a complex and inter-dependant system that involves crops and livestock and their management, soils, the environment and climate, as well as social and land-use dynamics. Changes in agricultural practices are therefore never simple or easy to track, but archaeobotanical and archaeozoological data generated over the past few decades informs us that they took place, sometimes at a very broad scale. The question we would like to address in this session is: what drove agricultural changes and innovations in prehistory, when farming practices were mostly locally rooted and depended largely on household level decision-making and what were their social and ecological consequences?

Archaeology has the ability to tackle this complex network of processes and consequences by interlinking multiple proxies that can be evaluated independently, combined and contrasted with multiple sources of information. This session welcomes papers that deal with all types of archaeological proxies that are combined with data on agricultural dynamics at the local, regional or supra-regional scale to understand the scale of agricultural change, innovation and productivity, as well as the effects on social and ecological systems, including land cover and land use change. We particularly welcome multi-proxy and systemic approaches to the understanding of agricultural decision-making in the past.

This session is supported by the AgriChange Project (<https://agrichange.duw.unibas.ch>), funded by the Swiss National Science Foundation (PP00P1\_170515) and the LandUse6k working group of PAGES (<https://landuse.sas.upenn.edu/>).

**ABSTRACTS:**

1 **MODELLING HUMAN-ENVIRONMENT INTERACTION PATTERN(S) OF BRONZE AGE COMMUNITIES OF THE ADRIATIC SIDE OF CENTRAL-SOUTHERN ITALY**

**Abstract author(s):** Lucci, Enrico (Department of Antiquities, Sapienza - University of Rome)

**Abstract format:** Oral

The Adriatic side of Central-Southern Italy embraces a significant ecosystem variability. During the 2nd millennium BC, this area witnessed the emergence of more complex settlement patterns and demographic growth, as well as new economic and socio-political patterns. Long-lived settlements, characterized by a steady subsistence economy and engaged in exchange networks with the Aegean and Balkans, arose mainly along the south-eastern coastal area. At the same time, inland settlements, which appear to have a less permanent nature, show great capacity of exploiting diverse environmental niches, resulting in a surplus and enabling them to fully participate in the exchange network. Thus, the interplay of structural (demographic growth, environmental productivity and increasing technologies - e.g., arboriculture), sociocultural and geopolitical factors produced multiple trajectories of human-environment interactions over the area under scrutiny.

In this presentation I will propose GIS land use models focused on specific case studies, notably, Bronze Age settlements of highly surveyed inland (e.g. Fucino Lake, Tavoliere plain and Murge) and coastal territories (notably of Molise and Apulia regions) of the Adriatic side of Central-Southern Italy. Discussion will be focused on the integrated approach for synthesizing and analysing economic, sociocultural and environmental data in order to visualise how diverse environmental niches were selected and exploited by the various communities and how these choices transformed in relation to changing socio-political patterns. The analysis will consider both a macro-scale perspective based on regional settlement strategies, palaeoenvironmental proxies and geomorphological aspects and a micro-scale perspective based on land use analysis of the territory surrounding each settlement, possibly used for farming activities and procurement of natural resources (e.g. wood). Pastoral activities and potential mobility strategies will be also integrated in the analysis. This study represents one of the first efforts to produce an overarching model of human-environment interaction for this wide area of the Italian peninsula.

2 **SEEDS OUT OF WATER. UNDERSTANDING WATERLOGGED PLANT ASSEMBLAGES FROM SOILS WITH HIGH ANTHROPOGENIC IMPACT**

**Abstract author(s):** Quaglio, Valentina (Università degli Studi di Padova) - Osti, Giulia (Digital Heritage Research Lab, Cyprus University of Technology)

**Abstract format:** Oral

The “Terramara of Pilastrì” excavation project aims at investigating the archaeological site of Pilastrì (Bondeno, Emilia Romagna, Italy), located in the broader framework of the Terramare cultural system, which characterised the Po Plain during the Middle-Late Bronze Age (1650-1200 B.C.). Since the very beginning of the project, the collaboration of a multidisciplinary team of professors, students, different institutions and organisations allowed the development of several research areas. Among those, the archaeobotanical investigations saw the involvement of different research groups for micro and macroremains, resulting in a rather complex interpretative framework.

The proposing authors dealt with the study of the carpological remains, to obtain a more detailed characterisation of plant husbandry practices; their study, incidentally, required a deviation towards the evolution of the surrounding natural environment. The archaeological context - although suitable for the preservation of plant remains - lacked integrity: the quality of the samples was partially compromised by deep ploughings. Additionally, the result of bioturbation phenomena constituted a major issue, returning a fragmentary picture.

As a result, the interpretation of the waterlogged seeds found all over the site has been an object of strong debate. The phytosociological comparative analysis was effective to disclose the last and very recent phases of landscape evolution, though it left several questions unanswered. This contribution will present the recent developments of the studies conducted on the waterlogged seed assemblages, proposing a fresh and data science-driven approach to their interpretation. Mixed analysis techniques and joint interpretation of the charred and the waterlogged archaeobotanical records will be presented and discussed, proposing actual and potentially scalable solutions.

### AN INTEGRATIVE MULTIVARIATE APPROACH TO RECONSTRUCT SUBSISTENCE FROM THE BRONZE TO IRON AGE IN THE SOUTHERN AND CENTRAL LEVANT

**Abstract author(s):** Vermeersch, Shyama (Institute for Archaeological Sciences at University of Tübingen; Collaborative Research Centre 1070 at University of Tübingen) - Riehl, Simone - Starkovich, Britt (Institute for Archaeological Sciences at University of Tübingen; Collaborative Research Centre 1070 at University of Tübingen; Senckenberg Centre for Human Evolution and Palaeoenvironment at the University of Tübingen) - Kamlah, Jens (Collaborative Research Centre 1070 at University of Tübingen; Institute of Biblical Archaeology at University of Tübingen)

**Abstract format:** Oral

Faunal and botanical studies are at the heart of reconstructing subsistence strategies and agriculture in past societies. Understanding these practices helps us place social and political developments in their wider contexts. Additionally, we know that animal husbandry and crop cultivation are commonly interlinked in recent and historical agricultural systems. However, the results of faunal and botanical analyses in archaeology are often treated separately, depriving us of a holistic understanding of past subsistence practices. In this talk, we present a customised method to integrate faunal and botanical remains for understanding both components in mixed (pre)historic farming economies. We use multivariate statistics – specifically correspondence analysis – combined with independent variables such as chronology, mean annual precipitation, and elevation. We apply this method to investigate developments in farming systems from the Bronze through Iron Age in the southern and central Levant (3,600 – 586 BCE). We see diachronic developments in animal husbandry and crop cultivation, a distinction between sites in lower and higher mean annual precipitation zones, and a difference between sites at different elevations. As such, this method allows us to not only identify human but also environmental components related to shifts in farming systems and diet. We advocate for making such integrative analyses common practice in bioarchaeology, because only then will we be able to obtain a more holistic picture of the economic basis of past societies.

4

### AGRICULTURAL DYNAMICS OF IMPERIAL “PAUSES”: A CASE STUDY FROM IRON AGE ANATOLIA

**Abstract author(s):** Marston, John (Boston University) - Çakırlar, Canan (University of Groningen) - Meiggs, David (Rochester Institute of Technology)

**Abstract format:** Oral

Distinct agricultural regimes have been documented to accompany the rise of empires and their expansion into new territories. Agricultural systems in imperial peripheries are often aimed at intensive, extractive production, eroding the autonomy of local authorities and individual farmers and herders, with distinct environmental consequences. Such agricultural systems are often substantively different from those in place prior to imperial expansion. In contrast, agricultural regimes during imperial “pauses”—archaeologically identifiable moments of autonomy and local decision making—such as those that follow imperial collapse are less well understood. This paper argues that such periods are critical for understanding both imperial agricultural dynamics and agricultural decision-making processes among small-scale, independent communities.

A long-term record of both plant and animal use from the site of Gordion in ancient Anatolia renders it a valuable case study of agriculture during both imperial and inter-imperial periods. The Early Iron Age (c. 1100-900 BCE) is a key period of autonomy, falling between the collapse of the Late Bronze Age Hittite Empire and the rise of the indigenous Iron Age Phrygian state. In this paper I reconstruct agricultural practices from archaeobotanical and zooarchaeological remains, drawing on nascent isotopic research to help identify agricultural strategies and their ensuing environmental implications. The “peak” imperial period before and the “nascent” imperial period following the Early Iron Age help to bookend that period of local autonomy and decision making, highlighting how practices differed during a period of small-scale settlement with a local economic orientation. The implications of this case study for the broader question of imperial environmental legacies in agricultural landscapes are considered.

5

### ANTHROPOGENIC LANDSCAPES OF THE LATE BRONZE AGE IN THE SOUTHERN URALS: THE IMPACT OF PASTORALISM ON THE ECOSYSTEM

**Abstract author(s):** Shcherbakov, Nikolai (Laboratory of method and methodology research, Bashkir State Pedagogical University) - Golyeva, Alexandra (Institute of Geography, Russian Academy of Sciences) - Shuteleva, Iia (Laboratory of method and methodology research, Bashkir State Pedagogical University)

**Abstract format:** Oral

A group of sites belonging to the Late Bronze Age was studied on the territory of the Southern Urals. Geographic location of the studied area - between the European part of Eurasia and Central Asia - makes it possible to trace the movement dynamics of people and technologies. The object of the study was a group of sites united by the middle course of the Urshak river. This area has a high concentration of sites belonging to the late Bronze Age and subsequent periods (early Iron Age and early Middle Ages). The Southern Urals became a contact zone between the Srubnaya archaeological culture and the Andronovskaya archaeological culture (1770 and 1630 CalBCE). This array of sites showed the trend in the development of pastoralism. The population of the Andronovskaya archaeological culture moved from arid climate of the Central Asia to humid climate of the Southern Urals. Multi-proxy analysis including paleosoil analysis, archaeobotany, archaeozoology, isotope analysis, ADNA analysis of settlements and burial mounds made it possible to assess the consequences of the ancient people’s activities on the environment. Representatives of the Andronovskaya culture brought traditions of pastoralism and the building tradition of using simple mud bricks from the Central Asia. In the Southern

Urals, this population used gypsum to build houses. Artificial layers of gypsum reached one meter. Accumulation of large amounts of gypsum rocks within the ancient settlement site resulted in contamination of the environment with gypsum. In some cases, the human impact on ancient landscapes has been so profound that local soils still remain significantly affected even after hundreds and thousands of years after ending impact. The properties of the modern soil inside the cultural layer were directly affected by the Late Bronze Age human activities, with 3.5 thousand years being an insufficient timescale to restore the natural soils.

6

### MOUNTAIN AGRICULTURE IN THE NORTH CAUCASUS: POLLEN SIGNALS IN PEAT PALEOARCHIVES, ARCHAEOLOGICAL DATA AND SIGNS OF SLOPE TERRACING

**Abstract author(s):** Ryabogina, Natalia (Tyumen Scientific Centre SB RAS; Institute of Physicochemical and Biological Problems of Soil Science RAS) - Yuzhanina, Eleanora (Tyumen Scientific Centre SB RAS) - Troshina, Alla (Institute of Archeology RAS) - Borisov, Aleksandr (Institute of Physicochemical and Biological Problems of Soil Science RAS)

**Abstract format:** Oral

Agriculture development in the North Caucasus (Russia) has a few archaeobotanical and archaeological sources, often poorly dated. Therefore, we tried to find alternative data and traced the appearance of agricultural signals from profiles of four mountain peatlands. The presence of cereal pollen, weeds and specific NPP associated with agriculture have been compared with archaeological data.

The earliest pollen markers were found in the 7th millennium BC simultaneously in mountain peat from the Eastern, Central and Western Caucasus. It is crucial that in the Eastern Caucasus this is consistent with the presence of Neolithic settlements in the mountainous zone, while in the Western and Central Caucasus until now there has been no convincing archaeological data confirming the agriculture.

The next interval with agricultural signs appears at different times. In the Eastern Caucasus at the end of the 5th - the middle of the 3rd millennium BC during the existence of the Ginchi settlements. In the Central Caucasus (the end of the 4th millennium BC) and the Western Caucasus (in the first half of the 4th millennium BC), it is associated with the Maikop population and the late Kuro-Araxes.

Later, in the Central Caucasus from the middle of 2nd to the middle of the 1st millennium BC pollen signal associated with the emergence of Koban agro-terraces. Intensive agricultural markers consistent with the construction of mountain terraces are also identified in the Eastern Caucasus in the early Iron Age from the 5th century BC and reaches its maximum 9-12 centuries AD. In the Western Caucasus, terracing has not been detected, and cereal pollen dated of 10th-3rd centuries BC and later.

Such data raise new questions about the age of the first appearance of mountain agriculture and paleoeconomy activity in different parts of the North Caucasus.

Supported by the Russian Science Foundation, project 19-18-00406.

### PRE-HISPANIC URBAN AGRICULTURE ON VOLCANIC ASH SOILS: GEOARCHAEOLOGICAL COMPARISON OF TWO SITES FROM CENTRAL AND WESTERN MEXICO USING LIDAR

**Abstract author(s):** Dorison, Antoine (CNRS - UMR7041 ArScAn Archaeology and Sciences of the Antiquity, team Environmental Archaeologies) - Elliott, Michelle (CNRS - UMR7041 ArScAn Archaeology and Sciences of the Antiquity, team Environmental Archaeologies; University Paris 1 - Panthéon Sorbonne) - Clayton, Sarah (Department of Anthropology, University of Wisconsin-Madison) - Pereira, Grégory (CNRS – UMR8096 ArchAm Archaeology of the Americas)

**Abstract format:** Oral

The Central Mexican Highlands have concentrated human occupations since pre-Hispanic times. Their lake basins with volcanic ash soils constituted good farmlands in an economy without beasts of burden, though subtropical seasonality (humid/dry) – which constrains plants growing cycle – required the implementation of water management techniques. Agriculture was a major structuring principle in the settlement and urbanization processes and pre-Hispanic cities have even been qualified as “sustainable” (Isendahl and Smith 2013). However, research on pre-Hispanic settlement agriculture still presents gaps, beginning with the fact that current knowledge remains chiefly based on post-Conquest 16th century texts written by the Spanish settlers. In the latter and subsequent research, advanced wetland cultivation systems (i.e. raised fields) have received significant attention while simpler rainfed techniques, albeit providing the major part of the subsistence, have received much less notice. In parallel, archaeological works focusing on agrarian features remain rare, even though examples of such features are proliferating across Mesoamerica with the multiplication of Airborne Laser Scanning (ALS or LiDAR) surveys.

To tackle these issues, we present an investigation that addresses the place of agriculture in the urbanization process focusing on rainfed cultivation practices at two sites of the Central Mexican Highlands: Infiernillo (Basin of Zacapu, West Mexico) and Chicolapan (Basin of Mexico). We aim to compare the different intra-site and local agricultural strategies in these two sites, both area having experienced a population increase, an urban agglomeration process and ensuing economic changes between the 7th and the 14th century AD. We focus here on the first step of a novel methodology based on LiDAR-derived data consisting in the mapping of not only archaeological features, but also landforms and soils. Fieldwork (i.e. archaeological and pedological test-pits and analysis) will only be presented here as perspectives as it remains uncertain in 2021 pandemic context.

8 UNDERSTANDING COMMUNITIES THROUGH THEIR FARMLAND. CASE STUDIES FROM SOUTHERN ETRURIA (ITALY) BETWEEN FINAL BRONZE AGE AND FIRST IRON AGE

**Abstract author(s):** Sotgia, Agostino (Sapienza - University of Rome; RUG - University of Groningen)

**Abstract format:** Oral

Thanks to a specific GIS model, developed combining agricultural knowledge with information from landscape survey, excavations, palynological and archeozoological data, it is possible to define the land use of human communities.

The idea is that the reconstruction of the primary economy of communities not only allows us to better understand the relation between human and landscape but it also informs us about the very essence of these groups. It is well known, as Marxist theories have taught, that economic production refers not only to an economic configuration but also to a complex arrangement of different social and anthropological patterns within community life. In other words, the economic organization is the backbone of the social one. Since subsistence economies are the basis of economics in prehistoric times, it is necessary to understand them as much as possible. Moreover, as the ancient agricultural production in most cases is an exploitation of common and shared resources (commons), we must conceptualize it in terms of a communal production with its social implications.

The case study presented here shows how it is possible to better understand important historical phenomena through this “agro-economist” approach. In fact, it is precisely the changes in the strategies of primary economies that occurred during the end of the Bronze Age in southern Etruria that are at the basis of the revolutionary phenomenon of social development of the “proto-urban turning point” of the Iron Age, with the transition from villages to the first forms of (proto) cities. It is thanks to the reconstruction of the agro-pastoral production dynamics between 1150 and 850 BC. (different organization between sites, production specialization, gradual transition from collective ownership to private property) that it is possible to better understand this historical phenomenon of great importance for the development of all the communities of the Italian peninsula.

9 MOBILE MANAGEMENT OVER THE LONGUE-DURÉE: ISOTOPIC (87SR/86SR, δ18O) AND ZOOARCHAEOLOGICAL EVIDENCE FOR HERDING STRATEGIES IN PREHISTORIC AND ROMAN NORTH ITALY

**Abstract author(s):** Trentacoste, Angela (University of Oxford) - Nieto-Espinet, Ariadna (IMF-CSIC) - Guimarães-Chiarelli, Silvia (IMF-CSIC; CIBIO/InBIO) - Valenzuela-Lamas, Silvia (IMF-CSIC)

**Abstract format:** Oral

Livestock mobility, in the form of mobile pastoral strategies and seasonal movements, has long been considered a central part of animal management in the ancient Mediterranean. It is now increasingly recognised, however, that animal husbandry - including the nature and scale of herd mobility - was shaped by its social and economic context, as well as by the natural environment. Alongside terrain, land use, and the organisation of arable production, political and economic connectivity also presented incentives and obstacles to animal movement. This paper takes a long-term view of livestock management and mobility from the Bronze Age to the Roman period, integrating zooarchaeological, isotopic, and environmental data to investigate changes in animal management and mobility through time. Analysis of strontium (87Sr/86Sr) and oxygen (δ18O) isotopes from tooth enamel of sheep/goat and cattle provide new evidence for herd mobility, and information on the localisation of herding strategies and the ‘animal catchment’ of sites, as well as an indication of animals imported from further afield. Through integration with published zooarchaeological studies and environmental proxies, we aim to assess the changing dynamics of herd mobility and the role of economic connectivity – compared to local ecology – on production strategies.

10 IRON AGE AND ARCHAIC AGRICULTURE IN CENTRAL ITALY: INTEGRATING ARCHAEOBOTANY, ZOOARCHAEOLOGY AND STABLE ISOTOPES ANALYSIS

**Abstract author(s):** Gaveriaux, Fanny (Department of Earth Sciences, Sapienza University of Rome; Department of Environmental Biology, Sapienza University of Rome) - Motta, Laura (Kelsey Museum of Archaeology, University of Michigan) - Moses, Victoria (University of Arizona, School of Anthropology)

**Abstract format:** Oral

From the 10th to the 6th century BCE the populations of the Tyrrhenian region in central Italy underwent social, political and economic transformations, including nucleation and urbanization processes which led to the rise of the first city-states. These changes were associated with a demographic growth as well as a significant shift in settlement patterns and size that dramatically restructured life across the region. Previous scholarship postulated that, therefore, the population would have intensified and modified their agricultural practices. However, little is known about agriculture during this period, and only very recently new datasets became available. Here we propose a multi-proxy approach that integrates zooarchaeological and archaeobotanical data with carbon and nitrogen stable isotope analysis (Δ13C and δ15N) on charred cereal grains (barley and emmer). While the first method allows us to have an overview of crop productions and livestock husbandry, the second one permits to better characterize the farming practices used in the fields. This study compares the results from three sites, Tarquinia, Rome and Gabii that underwent this phase of proto-urbanisation and have provided archaeobotanical and zoological remains spanning the whole period.

11 AGRICULTURAL SYSTEMS, FORMS OF SOCIAL ORGANISATION AND LANDUSE IN THE VALENCIAN COUNTRY BETWEEN THE 6TH AND 1ST MILLENNIA BC

**Abstract author(s):** Jorda, Guillem (Dept. of Prehistory, Archaeology and Ancient History. University of Valencia) - Gordó, Salvador (Departamento de Geografía e Historia. University of La Laguna)

**Abstract format:** Oral

From the establishment of the first farming communities in the Valencian Country (Eastern Iberia) in the middle of the 6th millennium BC, until the beginning of the Roman presence, changes have taken place that firstly affect the forms of social organisation, with processes of aggregation and disintegration of the population, as well as phases with greater and lesser social complexity. At the same time, the agricultural system has undergone changes, moving from an intensive to an extensive model, with innovations that have also affected the appearance of new crops or the introduction of technological improvements such as the use of animals as draught power or the appearance of metal implements.

In this paper we have selected a series of sites that cover this chronological span and contrast different variables.

- Size of settlements/population volume
- Agricultural system
- Soil quality

Based on these data, it can be seen that intensive models only work when the population is dispersed, given the impossibility of maintaining it over large areas of land. On the other hand, when there are processes of aggregation of the population, a mainly extensive model is chosen, without ruling out the possibility of coexistence with small-scale horticultural production.

At the same time, it can be seen how the selection of crops is conditioned by the quality of the surrounding soils, and in this way, it can be observed how the introduction of metal tools and undemanding crops such as fruit trees made it possible to exploit areas that had not been previously occupied. In short, the study shows how there is a close relationship between the possibilities offered by the environment, technology, social organisation and the use made of the territory by the different farming communities.

12 NICE RICE, CAN I HAVE IT?: MODELLING PRODUCTIVITY AND SUITABILITY OF RICE FARMING DURING THE YAYOI PERIOD IN JAPAN

**Abstract author(s):** Brainerd, Leah - Crema, Enrico (University of Cambridge) - Madella, Marco (ICREA - CaSEs, Department of Humanities, Universitat Pompeu Fabra) - Yoshida, Akihiro (Kagoshima University)

**Abstract format:** Oral

The introduction of rice and millet farming to Japan during the Yayoi period (2,800-1,750/1,700 BP) was a significant turning point in Japanese history that subsequently led to the emergence of early states in the archipelago. Rice and millet agriculture were proliferated by migrant communities from mainland Asia; these communities spread into the Japanese islands interacting with the incumbent population of complex hunter-gatherers, the Jomon people. The introduction of wet-rice farming, in particular, brought major changes in settlement patterns and demography but its adoption was not uniform across Japan, with some areas showing limited to no reliance on the new subsistence strategy and others, after an initial adoption, even reverting to a predominantly hunting and gathering economy. The geographically diverse response to the continental subsistence economy is generally assumed to be reflecting the underlying variation in the environmental and climatic settings of the Japanese islands. However, this assumption remains untested and further exploration of the relationship between environmental and social factors are required to elucidate the diversity of local responses. This paper contributes to this research agenda by modelling the geographic variation in the suitability and productivity of wet and dry rice farming in the Japanese archipelago using ecological thermal niche modelling and retrodictions based on spatial autoregressive models. The latter are based on historic agricultural yield census data from mid-late 19th century Japan and extrapolated to the climatic conditions of the Yayoi period. We assess the limitations and the potential of the two approaches by comparing the two models against each other and their relative fit to the archaeobotanical fossil record.

13 CHANGING FARMING PRACTICES OF A LATE ANTIQUE RIVERSIDE RURAL SETTLEMENT IN THE GREAT HUNGARIAN PLAIN

**Abstract author(s):** Masek, Zsófia (Institute of Archaeology, Research Centre for the Humanities, Budapest) - Daróczy-Szabó, Márta - Daróczy-Szabó, László (Budapest History Museum) - Kenéz, Árpád (Independent researcher) - Pető, Ákos (Hungarian University of Agriculture and Life Sciences, Institute for Wildlife Management and Nature Conservation) - Rácz, Zsófia (Institute of Archaeological Sciences, Eötvös Loránd University)

**Abstract format:** Oral

The economic strategies of past communities are especially difficult to assess in a complex way, when the environmental and climatic reconstructions of the investigated landscapes are also in progress. New considerations may be raised when one site could be examined in several consecutive time periods and a comparison of each datasets is also possible.

Time and time again, new waves of eastern communities entered the Carpathian Basin over the millennia. Instead of pastoral practices, these communities mostly tended to settle down, interacting with new neighbouring societies that transformed them as a result, providing various responses to the environmental and social challenges.

In this local study, we would like to present the agricultural dynamics through a site, where a continuous habitation with strong cultural transformations can be traced. The examined time period is the late 4th – early 6th. c. AD. These horizons are referred to different ethnic groups (Sarmatians, Gepids), but today’s research uses these terminologies more as chronological concepts. Instead of a large number of Hun-period samples at the site, the results of the transformation processes of the 5th century can be grasped with a contrast of the previous and the following settlement horizons.

We would like to combine the studying of animal and plant resources, livestock management, as well as systematic archaeological evaluation. In the vicinity of the site which lies on the bank of the Tisza river, a mosaic-like landscape structure is determinant. In spite of limited opportunities of re-defining land use, changing dynamics and farming structures are revealed in both agriculture and animal husbandry. These processes coincide with the results of the archaeological assessment; however, there are several explanations for the agricultural changes, the possible causes of which are also discussed.

A. **THE VILLAGE AFTER THE CITADEL: THE AGROPASTORAL ECONOMY OF THE MEDIEVAL OCCUPATION OF NIĞDE-KINIK HÖYÜK (CENTRAL ANATOLIA)**

**Abstract author(s):** Castellano, Lorenzo (New York University, Institute for the Study of the Ancient World) - Campana, Douglas (US National Park Service - retired) - Crabtree, Pam (New York University, Department of Anthropology)

**Abstract format:** Poster

The multi-period mound of Niğde-Kınık Höyük (N-KH) lies in the northern fringes of the Bor-Ereğli plain, an agricultural rich region of southern Cappadocia (Central Anatolia), strategically located on the main routes connecting the Central Anatolian plateau with Cilicia and the Levant. Since 2011 the site of N-KH is under investigation by a joined NYU and Pavia University project. Within this framework, extensive archaeobotanical (wood charcoal and seed/fruit remains) and zooarchaeological research allowed to diachronically reconstruct the agropastoral economy orbiting around the site, throughout its long occupation history spanning from the Bronze Age to the Medieval period.

As part of this broader research project, the aim of this contribution is to communicate the zooarchaeological and archaeobotanical evidence from the latest occupation of N-KH, dating to the Seljuk/Early Ottoman period (ca. 1200-1450 CE). This evidence will be discussed within a broader diachronic framework, providing insights into the degree of continuity and discontinuity in the local and regional agropastoral system.

The changes detected in the archaeobotanical and zooarchaeological record during the Seljuk/Early Ottoman are interpreted as chiefly resulting from changes in the nature of the occupation and to the cultural proclivities brought by new populations settling the area. The latter instance might be suggested by the almost complete disappearance of pig (*Sus scrofa*) from the zooarchaeological assemblage. On the other hand, other aspects of the local agricultural landscape appear in continuum with the earlier tradition, as exemplified by the continuous attestation of botanical macro-remains of grapevine (*Vitis vinifera*), reflecting the long-standing importance of viticulture in the region.

B. **BIOARCHAEOLOGICAL APPROACHES TO FARMING PRACTICES AND PALAEOENVIRONMENT IN THE LATE NEOLITHIC SETTLEMENT OF VINČA CULTURE FROM ȘOIMUȘ-TELEGHI (HUNEDOARA COUNTY, ROMANIA)**

**Abstract author(s):** Malaxa, Daniel - Stanc, Simina - Danu, Mihaela (Alexandru Ioan Cuza University of Iasi) - Marc, Antoniu (Museum of Dacian and Roman Civilisation, Deva) - Bejenaru, Luminița (Alexandru Ioan Cuza University of Iasi)

**Abstract format:** Poster

Archaeological research conducted in 2011 on the Șoimuș-Teleghi site (Hunedoara County, Romania) revealed many discoveries (i.e., houses, pits with different destinations, ovens, ditches, ritual deposits, graves), belonging to the Neolithic, Bronze Age, Iron Age and Antiquity.

The present study tries to answer questions related to farming practices and palaeoenvironment in the southwest of Transylvania during Late Neolithic, from interdisciplinary perspective, valuing archaeozoologically and archaeobotanically the Vinča site of Șoimuș-Teleghi (5300-4500/4450 cal BC).

The archaeozoological sample comprises 1523 faunal remains which belong to mammals (85.82%), bird (0.06%), and mollusks (14.06%). Almost 86% of the identified mammal remains are of domestic species: cattle (*Bos taurus*), sheep (*Ovis aries*), goat (*Capra hircus*), pig (*Sus domesticus*) and dog (*Canis familiaris*). Slaughter ages suggest the management of cattle and sheep/goat for both secondary products (e.g., milk, traction) and primary ones (e.g., meat), while pig mostly for primary products (meat, fat).

The wild mammals represent about 14% of the identified remains belonging to this class. Some species, especially of large mammals, were hunted for meat: red deer (*Cervus elaphus*), wild boar (*Sus scrofa*), roe deer (*Capreolus capreolus*), wild horse (*Equus ferus*); others provided also leather or fur, such as hare (*Lepus europaeus*), beaver (*Castor fiber*), bear (*Ursus arctos*).

The skeletal frequency indicates that both domestic and wild animals were slaughtered in or near the settlement, as remains from all body regions were identified (excepting wild species with small number of remains: wild horse, wild donkey, aurochs, etc.). The presence of the freshwater mussel (*Unio* sp.) is an indicator that the Vinča community from Șoimuș-Teleghi practiced also the mollusk gathering for an additional source of food.

In our research, phytolith analysis represents another way to interpretation the cultural layers and makes possible the reconstruction of the settlement palaeoeconomy. Phytolith assemblages also offers information on the palaeoenvironment.

**INNOVATIONS, IDEOLOGY AND INTERACTIONS - THE NARRATIVES OF EARLY MODERN DECORATED EARTHENWARE**

**Theme:** 6. Material culture studies and societies

**Organisers:** Witte, Frauke (Museum of Southern Denmark) - Wennberg, Tom (Gothenburg City Museum)

**Format:** Regular session

Material culture has a symbolic value and can be used actively in social and economic relations. The time of the Reformation put focus on the relationship between the individual and Christianity, and the Renaissance challenged the medieval perception of art. These changes often demanded that each person should take a stand in the community as an individual. This position was communicated to the community through material culture.

One medium was pottery. In the 15th and 16th centuries potteries in various regions of Northern and Central Europe started to produce new forms, which can be decorated using new technologies, such as coloured glaze, slip-painting and Scraffito. The interaction between producer and customer after 1500 for a while came under the influence of the big religious and political questions of the time. This allowed expressing certain signals and values and a kind of personal choice of decoration. As the motives used were quite similar all over Europe, they can be interpreted as well-known symbols – both in connection with the bible and with rather profane aspects of life. Later, in the 18th century, also written statements appear on pottery. We must ask ourselves, if the material also was perceived as a kind of “everyday art”, being displayed and placing the owner in a social and cultural group.

This session aims to compare the motifs in a wider European perspective to discuss the question of understanding the decorations as symbols and the objects as art and representative pieces besides its function. Also chronology of the objects is relevant as it reflects the delay of adapting new fashion from south to north, which can shade light to the transport and implementation of ideas. We welcome papers presenting decorated early modern earthenware from all European regions with an emphasis on the motives and their meanings.

1

**NEW DATA ON 13TH-15TH CENTURY CERAMIC PRODUCTION IN BENEVENTO (CAMPANIA, ITALY): THE EXCAVATION OF THE MONASTERY OF SANT’ILARIO**

**Abstract author(s):** Rapuano, Silvana - Rotili, Marcello (Università della Campania Luigi Vanvitelli)

**Abstract format:** Oral

The present paper is focused on the preliminary results from the study of pottery coming from the site of the church of Sant’Ilario a Port’Aurea, located in the north-eastern area of the historic center of Benevento, in the southern Italy. The church was built in between the end of the 7th and the beginning of the 8th centuries and owes its name to the close Arch of Trajan, which was also known as “Porta Aurea” (i.e. Golden Gate) being, at that time, incorporated into the town walls. The first cenobitic nucleus was added to the cult hall soon after the construction. In particular, the fictile finds here analyzed and belonging to several ceramic classes, with strong technological differences, come from 13th-15th century strata formed in the area in front of the church and in the coenobium. Those finds and many other artefacts were dug up during the years 2001-2002 by the Archaeological Superintendency of Benevento, during a campaign financed with public funds allocated for the construction of the so-called Trajan Arch’s Park. However, since at that time the finds were not analyzed in depth and even the documentation on the excavations is still unpublished, the group of medieval archaeologists of DILBEC, at the University of Campania “Luigi Vanvitelli”, is currently working on it. The research is conducted under the scientific direction of Marcello Rotili, who carried out long-term research in Benevento, in agreement with the Superintendence of Archeology, Fine Arts and Landscape for the provinces of Caserta and Benevento, and aims to shed light on the production, dissemination and use of this kind of pottery in the Benevento area. In this framework, the preliminary results we present here are the first of a promising sequence.

2

**MODERN DECORATED EARTHENWARE IN THE NORTH OF FRANCE BETWEEN THE 16TH AND 18TH CENTURIES**

**Abstract author(s):** Vincent, Vaiana (INRAP)

**Abstract format:** Oral

This paper proposes to question the modern decorated earthenware discovered in the North of France. The 16th century shows a profusion of ceramics decorated with sgraffito, notably the Beauvaisis productions. In the region, no other potter’s workshop is known to have attempted the same type of decoration. Their reputation and success was such that they were later widely distributed in Northern Europe. Slip decorations succeeded them. At first dominated by the German workshops at Werra, several local workshops then tried their hand at this technique, creating their own decorative field with their subtlety. It will also be interesting, through certain consumption sites, to see the choices made for decorated stoneware. The decorations take up both religious and

secular themes and the choice of consumers, according to the nature of the site observed, may reveal important information. If the 17th century in the North of France was largely dominated by the arrival of majolica and earthenware from the Netherlands, the first regional earthenware factories (notably that of Lille) appeared at the beginning of the 18th century. The study of several production sherds from waster pits allows us to characterize for the first time as closely as possible this production from Lille, whose decorative repertoires were inspired both by the great center of Delft and by the productions of Rouen (in Normandy), from which many workers came. This paper will be based on the study of ceramics from both production centers and consumption sites, dealing with the motifs created/chosen, their possible symbolism, the chronology in the North of France and the adaptability of local pottery centers to compete with the large “international” productions with a wide distribution.

3 **PORTUGUESE CERAMICS AS A VEHICLE FOR EUROPEAN AESTHETIC SYMBOLIC MESSAGES (1550-1800)**

**Abstract author(s):** Casimiro, Tania (HTC NOVA University of Lisbon)

**Abstract format:** Oral

Portuguese ceramics were widely distributed in Europe from late 16th to early 18th century. These objects correspond to a large variety of wares mostly destined to the transportation of goods or used as table ware. Although blue on white tin glaze wares are the most abundant, red wares were also highly demanded. These presented decorations which enriched the aesthetic portfolio of European houses in a perfect balanced relation with Spanish, Italian, Dutch and English wares, all in circulation at the same time. These were high quality productions and destined to a wealthy market with many on-demand peculiar objects.

This paper discusses styles and decorations, their influences and originality and how can they help to build a historical narrative. Most importantly it aims to understand the symbolic demands that European populations made of tableware, through mythological, biblical, historical, and political representations and how Portuguese pottery workshops and artists responded to that demand.

4 **LEAVES, CIRCLES, WAVES AND MORE - DECORATED LEAD-GLAZED EARTHENWARES FROM THE GOTHENBURG AREA IN THE EARLY MODERN TIMES**

**Abstract author(s):** Wennberg, Tom (Museum of Gothenburg) - Gustavsson, Jeanette (Rio Göteborg) - Forsblom Ljungdahl, Veronika (Arkeologerna)

**Abstract format:** Oral

The production of slip-decorated lead glazed earthenwares on the west coast of Sweden from Early modern times is still a largely unresearched area. We are at this point not sure exactly what was produced locally and what was imported. We do have a general idea of what that could be though, and ICP-analysis has been done that starts to shed light on this subject. Much of the decorated pottery is likely to have been imported, possibly from present day Germany and Holland. This paper will suggest a general chronology of slip-decorated lead glazed earthenware in the urban contexts of Nya Lödöse and Gothenburg as we understand it today.

Introduction of slip-decoration on pottery in Nya Lödöse (1473-1624) is closely associated with the increased use of plates and bowls in the later period of the town during the second half of the 16th century. Before that time, decorated pottery is rare. The main motifs seem to be simple geometric and floral patterns. There are a few examples of birds and one or two examples of fish motifs. So far, no examples of other animals or human figures have been identified.

Gothenburg is the urban continuation of Nya Lödöse (1619-present). In general, the use of decorated larger plates and bowls continues in Gothenburg, but the motifs become more varied. There are primarily flowers and other vegetative motifs but other motifs like geometrical forms, animals and people are to be found. During the late 17th century, the tulip seems to be very popular but other motifs are used. In the late 17th and early 18th century there are two traditions emerging. One with simpler motifs for everyday use vessels and one with more elaborate motifs that depict cultural traits.

5 **THE PAINTED EARTHENWARE OF THE LOWER RHINE REGION - A CERAMIC MEDIUM AND ITS CULTURAL CONNECTIONS**

**Abstract author(s):** Röser, Christian (LVR-LandesMuseum Bonn; Rheinische Friedrich-Wilhelms-Universität Bonn)

**Abstract format:** Oral

For a long time, the painted earthenware of the Lower Rhine Region was regarded primarily as an autonomous phenomenon that reflected local everyday culture. In addition the misleading term ‘peasant pottery’ (“Bauernkeramik”), which was sometimes chosen for this ware, placed it in the context of lower social classes. However, these attributions did not do justice to the Lower Rhenish Earthenware, for the realities of its creation, production and distribution were far more complex. Its motifs and stylistics certainly show unique and characteristic features, but these can only be understood in an analysis that is trans-regional and also goes beyond the material of ceramics. Technical and stylistic traditions going back further in time place the Lower Rhenish Earthenware in a broad European perspective. The emergence of the production of polychrome painted earthenware in the Lower Rhine Region at the end of the 17th century and the establishment of a putting-out system through which this ware was exported, especially to the Dutch Republic, has to be seen as a consequence of economic changes and the shifting of trade routes for ceramics in Northwest Europe.

This contribution attempts to present these versatile connections and contexts and to incorporate the latest insights resulting from the BMBF project ‘Medium:Keramik – Produktion, Verwendung und kulturelle Bedeutung rheinischer Keramik mit Bildsprache und Symbolik in der frühen Neuzeit’, thus providing an overview of the current state of research and future perspectives.

6 **A NEW DISCOVERED POTTERY PRODUCTION SITE OF HORN-PAINTED SLIP WARE FROM DESSAU AT THE ELBE RIVER (SAXONY-ANHALT/GERMANY)**

**Abstract author(s):** Petzschmann, Ulf (Landesamt für Denkmalpflege und Archäologie Sachsen-Anhalt)

**Abstract format:** Oral

Recently finished excavations in the Early-modern suburb outside the town wall of Dessau investigated around 2000 sqms. of a densely built-up urban area. Wasters and other pottery production related finds give strong evidence for a long tradition of pottery production on the site from the 16th to 19th century, albeit no pottery kiln was found. One of the main products from Dessau was obviously horn-painted slip ware, which was found overall the place in almost every layer and every context. There are several well-dated closed find contexts like an earth cellar and several backfills in wells and cesspits which shed light on the development of the painted slipwares from around 1600, around 1750 and the first half of 19th century.

The paper presents plates, dishes and miniature vessels from each of these periods in chronological order. The various decoration techniques like chattered- and sgraffito-decoration, inscriptions and different ways of horn-painting give a good impression of pottery traditions in a minor town at a major river in central North-Eastern Germany. The geographical placement of Dessau connects this region to the North Sea and the southern Baltic. The presentation of these regional slipwares can give a basis to discuss the general development of horn-painted slipware throughout Northern and Central Europe.

7 **ADAPTATION OF NOVELTIES IN POTTERY PRODUCTION AND DECORATION IN POMERELIAN TOWNS IN POST-MEDIEVAL PERIOD**

**Abstract author(s):** Starski, Michal (Faculty of Archaeology University of Warsaw)

**Abstract format:** Oral

The paper aims to describe the changes in pottery production and the range of ceramic vessels used in the Pomerelian towns from the 16th to the 18th century (Gdańsk Pomerania). The main area of considerations will be the issue of introducing new production trends, new forms of vessels and their ornamentation, as well as the associated symbolism. The impact of the Reformation will also be the background for the observed changes, as well as local production trends and regional trade influences. This problem will be presented based on an analysis of selected collections from the principal city of the region, i.e. Gdańsk, and several smaller urban centres (such as Czluchów, Chojnice, Debrzno, Lębork, Puck and Skarszewy). As a result of this presentation, the similarities and differences in the adaptation of new products in post-medieval pottery, including the share of foreign products in the range of used vessels, will be outlined.

8 **FORGING IDENTITIES IN EARLY MODERN CARNIOLA: THE CASE OF LOKA PAINTED WARE**

**Abstract author(s):** Predovnik, Katarina (University of Ljubljana, Faculty of Arts, Department of Archaeology)

**Abstract format:** Oral

In central Slovenia, the former Duchy of Carniola, the production of decorated earthenware first began in the mid-sixteenth century. This so-called Loka Painted Ware (LPW) is characterized by polychrome painted and in some cases incised (sgraffito) decoration on white slip coating covered with transparent glaze. Large bowls and plates predominate, clearly intended for display. The decoration includes combinations of geometric and floral motifs as well as depictions of animals (birds, fish, deer) and people, both portrait busts and full-figure representations. Some vessels also bear inscriptions and dates. Production of LPW lasted at least until the early years of the seventeenth century, when it was replaced by various, more austere productions of slip-painted and monochrome-glazed pottery.

While the decorative techniques and motifs of LPW are undoubtedly derived from earlier and contemporary Italian ceramic wares, the vessel forms, stylistic execution, and preference for particular motifs, as well as the colour palette, are quite distinctive and original. LPW can therefore best be understood as a cultural hybrid that emerged under the conditions of increasing literacy, education, and both physical and social mobility of people during the Reformation and Renaissance. As an affordable local alternative to imported Italian majolica and sgraffito wares, LPW has been interpreted as a resource for the emulation of polite behaviour by the middle classes in the processes of cultural change and social differentiation of early modern Carniolan society. The presumed symbolic meanings of the painted motifs and year numbers will be discussed in terms of identity formation, using a relational approach to material culture that interprets artefacts as social agents forming networks of relationships with people, places, and other objects.

9 **FEASTING & DANCING - PURE JOY OR GUILTY PLEASURE? FESTIVITY MOTIFS ON VESSELS AND TILES FROM EARLY MODERN TIMES**

**Abstract author(s):** Krukowska, Olga (Archaeological Museum in Gdansk)

**Abstract format:** Oral

The article presents selected ceramic artefacts as stoneware jugs, Werra ware, stove tiles decorated with everyday scenes coming from early modern times. The artefacts have origins in Gdansk and they have got their analogies amongst the artefacts coming from Europe. Decorative motifs that are going to be presented are scenes with dancers, feasts and weddings. These scenes often imply some symbolic, hidden meaning we cannot always understand. One character I would like to draw the attention to is the seemingly unconcerned jester. A jester, so called a fool was often associated with joy, fun and jokes. Although feasting and dancing were portrayed in art for centuries and as decorative motifs they had various meanings depending on the epoch, a jester was always omnipresent in many fields of art and his symbolic meaning remained unchanged for centuries. Only the thorough knowledge of the epoch may enable us to understand the hidden messages.

10 **FOR ONE KNIGHT ONLY? SYMBOLISM AND MEANING IN THE DECORATION OF STENHOUSE REDWARE CERAMICS**

**Abstract author(s):** Hall, Derek (Independent Contractor)

**Abstract format:** Oral

Amongst the limited number of pottery kilns and workshops so far discovered in Scotland is the Scottish Redware production centre at Stenhouse near Falkirk in the Forth Valley. First discovered in the 1950's during sand quarrying by the Carron Iron Company the site and pottery assemblage were finally written up by the author twenty years ago and a further adjacent part of the pottery was excavated by him in the early 2000's. This example of a late 15th/16th century Scottish Redware production was distinguished by the use of a distinctive group of symbols and decorations on the pottery that have been linked to the site's ownership or patronage by the Knights of St John of Jerusalem at their preceptory of Torphichen which lies 14 and a half Kilometres to the South of the site. This paper will discuss the use and meaning of these decorative styles from the perspective of Scottish pottery studies.

11 **A FORGOTTEN ART HISTORY?**

**Abstract author(s):** Johansen, Iben (Museum Sønderjylland)

**Abstract format:** Oral

This presentation will start with the simple question: Is decorated Danish pottery from 1500-1800 art? The question is interesting because pottery, and decorated household items in general, have been written out of western art history. In recent years it has gotten a revival as a beloved medium in contemporary art.

To answer this question, there is a multitude of other questions that needs to be answered first. How has the definition of art changed over the centuries, and how does the decorated pottery fit into that concept in different periods? Do we have sources, which can inform us on the perception of pottery?

At the same time, we must also look at the Danish term "Folkekunst" (Folk Art), which was first used in the latter part of the 19th century. Under this term decorated pottery is hobbled together with furniture and other decorated everyday items, which at the time were characterized as folksy and implicitly uncouth in style. In the Western art historical canon, it is a rule that these everyday art mediums are excluded for unsaid reasons. From the earliest times art historians view all mediums as important in understanding art history – everyday objects as well as ceremonial. Up until the ancient Greeks the art of the decorated vase or plate was an important part of art history. But from about the Middle Ages up until about a hundred years, ago decorated pottery was hardly mentioned at all. It returns into art historical writing around the start of the 20th century, where the new avantgarde movements expanded the then very narrow definition of art (painting, sculpture, architecture). From then on everything could be art. In that light we would now define decorated pottery as art, but would it have been, when it was created?

12 **EVERDAY ART? EXPRESSION BY SYMBOLISM ON EARLY MODERN EARTHENWARE IN SOUTHERN SCANDINAVIA**

**Abstract author(s):** Witte, Frauke (Museum of Southern Jutland)

**Abstract format:** Oral

During many periods of human history, common people's art was dominated by decorated pottery.

Compared to the preceding period, dramatic changes in the ceramic tradition in Southern Scandinavia become apparent from the beginning of the 16th century: potters - under influence from further south - introduced new vessel forms and started decorating the wares completely different. In this way, the earthenware acquired a completely alternate appearance and aspects of the ornamentation took on the hitherto unknown function of expressing certain signals and values (i.e. knowing the bible).

These changes in the ceramic tradition took place at the same time as the Reformation put focus on the relationship between the individual and Christianity, and the Renaissance challenged the medieval perception of art. The new vessel forms and ornamentation which characterise locally produced earthenware through most of the 16th and into the 17th centuries reflect the need of the

owners to either distinguish themselves visually from their surroundings or to be part of a bigger group. These changes in forms and especially ornamentation reflect a new development towards the use of meaningful symbolism.

In the past Southern Scandinavia societies ways of visually expressing personal beliefs and statements were limited. One such way was art. In contrast, pottery has over a very long period brought art into all homes, from the rural farm to the castle. Only few were able to represent status and decorate through the choice of books, tapestries, and paintings, whereas all levels of society used ornamented pottery whose different motives and forms developed into "everyday art" which was displayed, e.g. hanging on the wall.

287 **ECONOMIC AND TECHNOLOGICAL NETWORKS OF THE EURASIAN STEPPES**

**Theme:** 4. Globalisation and archaeology

**Organisers:** Gleba, Margarita (Ludwig Maximilian University of Munich; University College London) - Daragan, Marina (Institute of Archaeology, Ukrainian National Academy of Science)

**Format:** Regular session

The Eurasian Steppe region was fundamental in the development of multiple technologies and transregional networks of economic exchange long before the establishment of the Silk Roads. Far from being a periphery, the Eurasian Steppe region was the crucible in which fundamental technologies, languages, ideas and even pathogens originated and spread. Recent studies highlighting the exceptional scale and volume of Eurasian metallurgy and the emergence and spread wool textile technology in Eastern Europe, the Urals, Western Siberia and Kazakhstan are demonstrating that the Eurasian Steppe societies were at the heart of these technological development since the Bronze Age. Yet, although large-scale historical narratives spanning Europe and Asia have recently been gaining momentum, research dealing with specific technologies across this vast region remains disjointed, making it difficult to understand the broader patterns. The long-standing focus on headline-generating 'shiny' objects found in burials has led to the neglect of the necessities and realities of the complex economic systems, that required large-scale infrastructures to access raw materials and finished goods.

The session will consider sources of materials and objects (food, wool, leather, metals, wood etc.) and their production technologies (metallurgy, animal husbandry, textile production) with the aim of reconstructing economic and technological networks which developed across the Eurasian Steppe region in its broadest geographical expansion from the Bronze Age until the end of the 1st millennium BCE. We are particularly keen to see submissions which explore innovative scientific approaches to explore developments across time and space.

**ABSTRACTS:**

1 **SHEEP AND WOOL: EURASIAN STEPPE PASTORAL CULTURE INPUT IN WOOL INDUSTRY DEVELOPMENT**

**Abstract author(s):** Shishlina, Natalia (State Historical museum) - Orfinskaya, Olga (Centre of Egyptological investigation, RAS) - Roslyakova, Natalia (Samara State University of Social Sciences and Education)

**Abstract format:** Oral

The Bronze Age of northern Eurasia is characterised by major socio-economic changes. A secondary products revolution defined an overall trajectory in these global economic transformations. Innovative changes in fibre technologies led to appearance of woven wool textiles and production and consumption of new types of clothing.

The transmission of wool technology was a result of contact between communities in the steppe and their southern neighbours in early 3000 BC. In subsequent periods wool textiles 'travelled' from south to north with migrating population groups, where they were rapidly assimilated into local technical systems. This assimilation and the emergence of secondary products economy based on wool textiles was, most likely, facilitated by widespread of mobile sheep/goat herding, which became a dominant economic model in mid-3000 BC. In the last quarter of 3000 BC a wider preference for wool textile gradually spread, stretching north into the forest-steppe and forest zone and then from west to east. The production of wool textiles was fully integrated into the social economy of Eurasian pastoralists and wool textiles became increasingly widespread across northern Eurasia, spreading east towards the Urals and across Siberia and Kazakhstan.

2 **PRACTICE NOT CULTURE: ON THE UTILITY OF THE COMMUNITY OF PRACTICE CONCEPT FOR CERAMIC TECHNOLOGY ON THE EURASIAN STEPPE**

**Abstract author(s):** Rose, Nicole (Independent Researcher)

**Abstract format:** Oral

The Eurasian Steppe has been characterized by such terms as "highway" (Andersson 1929) or "spread zone" (Nichols 1998; Malory 2014) throughout its history of study. Though our understanding of the mechanism by which such a corridor developed has transformed over time from long-distance migration to overlapping seasonal cycles of pasture exploitation (Shishlina 2001; 2008; Frachetti 2008), scholars have consistently identified the role of mobile pastoralism in spreading languages, genes, materials, and technologies across Inner Eurasia. Yet mobility is implicated in not just the spread of technologies but in the construction and main-

tenance of tradition. Here I propose the application of an increasingly popular concept in archaeology to Eurasian steppe contexts: “community of practice” (Lave and Wenger 1991). Such a concept allows us to discuss what Frachetti (2012) termed “nonuniform institutional complexity” within and between distinct societies as developing in social networks unfolding at various scales dependent on the form of technological practice. For everyday technologies such as ceramics, on the Sal-Manych steppe, for example, a widespread community of practice whereby low investment technology was produced and curated in remarkably consistent ways persisted from the fifth millennium BCE through second millennium BCE as long as the “region” (de Certeau 1984, 126) of pastoral movements was maintained. With the social and economic transformations of the first millennium BCE, communities of practice would diversify in terms of ceramic technologies as steppe societies transitioned to historically-recognized pastoral nomadism, becoming more localized even as some social networks grew increasingly global.

3 **NOMADLAND: EXPLORING BRONZE AGE POTTING TRADITIONS OF SOUTHEAST KAZAKHSTAN**

**Abstract author(s):** Dupuy, Paula (Department of Sociology and Anthropology, Nazarbayev University) - Amicone, Silvia (Competence Center Archaeometry Baden-Wuerttemberg, Eberhard-Karls-Universität Tübingen; UCL Institute of Archaeology, University College London) - Mathur, Arvin (Department of Anthropology, University of Wisconsin-Madison)

**Abstract format:** Oral

Through regular interactions with their neighbors, the diverse groups of the Bronze Age Eurasian steppe (2500-800 BCE) formed dynamic interregional networks that saw the proliferation and persistence of shared material cultures over a vast geographic area. Some amount of cultural signaling related to these connections is demonstrated through handmade ceramics that repeat a narrow range of forms and finishes across the Eurasian steppe. Historically, such stylistic uniformity in regional potteries led scholars to posit that the people may have been similar too. However, recent archaeometric studies contradict this idea by revealing considerable diversity in both genetics and subsistence practices throughout the region. These data have therefore brought into question the utility of pottery studies to achieve anything but a gross description of Bronze Age communities. This talk stresses the need for a holistic approach to studies of material culture, combining both macro- and micro-scale technological studies, in order not to lose sight of the actual people who drove defining transformations in the Bronze Age. We provide a combined petrographic and formal analysis of pottery from the Semirech'ye region of southeastern Kazakhstan to examine diachronic technological traditions with a special focus on routines of selection and raw material processing. Our results demonstrate site-specific technology as well as traits that permeate both time and space. This microcosm of unity and diversity in crafting practices shows the potential of pottery as a proxy for studying deep-histories of human-environment interactions among different communities of practice. Results illuminate how and to which level technological adaptations connect people in the Bronze Age beyond the social signals as seen from stylistic-typological studies.

4 **SAKA-SCYTHIAN GOLDSMITHING: EVIDENCE FROM ELEKE SAZY AND SHILIKTY BURIAL COMPLEXES (KAZAKHSTAN)**

**Abstract author(s):** Amirova, Saltanat - Martínón-Torres, Marcos (University of Cambridge)

**Abstract format:** Oral

Gold is a prominent component in the material culture of the nomadic cultures that inhabited the Eurasian Steppe in the Bronze and Iron Ages. However, the scarcity of studies of contextualised finds from modern archaeological excavations has constrained our ability to discuss the development of technological traditions, the provision and value of raw materials, cross-craft interactions, or the role of gold in funerary rituals. Here we present an initial contribution to these topics through the analysis of gold assemblages recovered from two kurgan complexes, constructed by the Saka-Scythian cultures in Eastern Kazakhstan around 800 - 400 BCE. Recent excavations revealed a few kurgans with rich goldwork assemblages, some left intact or only partially looted. We employed two portable, non-invasive analytical techniques: digital microscopy to identify technological features and usewear, and portable X-ray fluorescence (pXRF) for elemental analysis. The results show remarkably different goldworking techniques, ranging from the application of wrought sheets on organic substrates through to solid casting, granulation and inlaying. Correlations between technology, composition and usewear are suggestive of different modes of sourcing, crafting and using gold. In addition, thousands of gold microbeads, barely visible to the naked eye, highlight the value of skill and labour in addition to that of the material. These initial results give useful pointers for future research, which we plan to pursue as the project expands.

5 **TECHNIQUE AND TECHNOLOGY OF SCYTHIAN BRONZE ARROWHEAD CASTING**

**Abstract author(s):** Daragan, Marina (Institute of Archaeology of Ukrainian National Academy of Sciences)

**Abstract format:** Oral

The most ubiquitous category of Scythian material culture – the bronze arrowheads – is paradoxically the least studied to date. First and foremost, this concerns one question: how were they cast? No definitive conclusions regarding the technology of arrowhead casting have been reached. Some sources suggest the use of a metal mould for these purposes, while others propose the use lost-wax casting technology. Our understanding of the casting technology is fundamental, since it affected the organisation of the manufacturing process of such a numerous category of material and,

as a consequence, the supply of Scythian warriors with necessary weapons. In order to solve this problem, more than 12,000

arrowheads from 455 quiver sets from burials and layers of settlements found in the steppe and forest-steppe zone of the Northern Black Sea region were studied, and several experiments were carried out casting the arrowheads in a metal mould, using

metal moulds to obtain wax models, and lost wax casting. Comparative metallographic analyses were carried out for some of the original Scythian arrowheads and their analogues, cast in different ways. The results of the experiments indicate the casting of

arrowheads using the lost wax technique. These data were confirmed by the results of metallographic analyses: the difference in the cooling rate of the crystallisation of arrowheads obtained by different casting methods affected the parameters of the crystal

structure of their alloy. The dendritic structures of the analysed original Scythian arrowheads have a great similarity. Uniformity of the dendritic parameter (thickness of dendritic branches) is observed when moving from the surface into the depth of the

arrowhead. This indicates the casting of the arrowhead most likely using to the lost wax model, and probably in a disposable ceramic rather than a metal mould.

6 **USING ARCHAEOLOGICAL MATERIALS SCIENCE TO TRACE ECONOMIC AND TECHNOLOGICAL NETWORKS OF THE EUROPEAN SCYTHIANS**

**Abstract author(s):** Gleba, Margarita (Ludwig Maximilian University of Munich)

**Abstract format:** Oral

Scythian material culture is first and foremost associated with shiny gold objects, yet it is the perishable materials such as leather, textiles, wood and bone that constituted its bulk, as demonstrated by the spectacular Scytho-Siberian burials preserved by the permafrost in the Altai region of Russia. The preservation conditions are not as favourable in the Ukrainian steppe, but a large number of fragmentary organic remains does survive, for example in kurgan burials at Bulgakovo, Ilyinka and Vodoslavka. Recent developments in archaeological materials science allow using various scientific analytical techniques to trace economic and technological networks of the European Scythians. This paper will provide an overview of the recent and ongoing research into characterisation and provenance of archaeological textile, leather, wood and bone artefacts from the Scythian burials excavated in Ukraine. The multi-analytical approach includes technological analysis, fibre and dye identification of textiles (using SEM and HPLC-DAD); species identification of wood (using microscopic techniques); species identification of leather (using ZooMS and SEM); and characterisation of pigments (using SEM, FTIR, RAMAN, multispectral imaging). The new data provide a rich source of information about the materials and techniques used for the production of Scythian tools, weapons and elements of clothing. In some cases, their provenance reflects complex networks of their acquisition, thereby expanding our understanding of Scythian economy.

7 **USING ZOOMS TO IDENTIFY LEATHER SPECIES FROM THE 1ST MILLENNIUM BC BURIALS OF THE EURASIAN STEPPES**

**Abstract author(s):** Brandt, Luise (GLOBE Institute) - Daragan, Marina (Institute of Archaeology of the National Academy of Sciences of Ukraine, Kiev) - Pankova, Svetlana - Chugunov, Konstantin (The State Hermitage, St. Petersburg) - Gleba, Margarita (Ludwig Maximilian University of Munich)

**Abstract format:** Oral

Excavations of kurgans across the Eurasian steppes yielded extremely well preserved burials of various Scythic cultures of the first millennium BC. While the magnificent golden decorative objects found in many of these burials have received much attention, other, particularly organic artefacts made of leather, have rarely been investigated, despite their importance to the everyday life of their nomadic owners. These objects provide a unique opportunity to gain insights into the animal exploitation, leather technology and use, and perhaps also the beliefs attached to the animals so frequently depicted in the Scythian Animal Style art. Until recently, identifying species of the leather has been difficult since morphological methods for identifying skin materials are complicated by interspecies variation and, particularly in archaeological environments, frequent degradation of the diagnostic surfaces. Using the protein-based species identification method ZooMS (Zooarchaeology by Mass Spectrometry), we analysed 63 leather samples from quivers and articles of clothing from the seventh century BC Arzhan-2 kurgan in Tuva, Russia and 13 different Scythian kurgan sites in Ukraine, primarily of the fourth century BC. Also articles from the southern Siberian Oglakhty cemetery, Burial 4, were sampled. This site belonged to the Post Scythian group (1–4 c.AD) that inherited many traditions of the previous period. The different geographical locations of the finds allowed testing for the variable degree of leather preservation in different environments. Most species identified are domesticates such as equids, bovids and ovicaprids, demonstrating that people in the steppe primarily relied on herded animals for their raw materials. At least two samples, however, belong to wild carnivorous species and one is human, confirming for the first time the claim of the Greek historian Herodotus that Scythians used the flayed skin of their enemies to make quiver covers.

8 **PIGMENTS OF EUROPEAN SCYTHIANS LOCATED IN THE PONTIC STEPPE: PRELIMINARY RESULTS**

**Abstract author(s):** Leighton, Chloe (UCL) - Gleba, Margarita (LMU) - Radivojevic, Miljana (UCL) - Daragan, Marina (Institute of Archaeology of the National Academy of Sciences of Ukraine) - O’Grady, Caitlin - Phillipson, Ines (UCL)

**Abstract format:** Oral

Recent studies on the technologies and economic exchanges that occurred along the Eurasian Steppes have begun to address the prejudices of the conventionally accepted historiography of ‘East-West’ exchange. Archaeologists, by expanding research to

SCYTHIAN FUNERAL FEAST AS A REFLECTION OF SCYTHIAN ECONOMICS: THE CASE OF ROYAL SCYTHIAN ALEXANDROPOL KURGAN

**Abstract author(s):** Daragan, Marina - Polin, Sergei (Institute of Archaeology of Ukrainian National Academy of Sciences)

**Abstract format:** Oral

The Royal Scythian Alexandropol kurgan, dated to the last third of the 4th century BC, was 24 m high and 85 m in diameter. The funeral feast (trizna), discovered in the course of the recent re-excavation of the Alexandropol kurgan, contained the remains of no less than 457 Greek transport amphorae. These amphorae had been produced in 13 different centers and had 14 different shapes. Combining these with the amphorae, which were found inside the kurgan’s burial chambers, the total number of amphorae discovered in Alexandropol kurgan amounts to 479 units. Using the standard amphora volume, we estimate that the participants of the feast consumed between 5663 and 7242 litres of imported Greek wine, in addition to the beverages of local origin which are indicated by the presence of Scythian moulded vessels. The transport of such a quantity of wine to the distant steppe raises the question of economic supply logistics. Where did this wine come from and how was it delivered to the burial site? It is important to consider not only the weight of 6000 liters of wine itself, but also the weight of the amphorae, which based on our calculations, would have totaled 10–11 tons. In addition to the wine, the participants of the funeral feast at Alexandropol consumed 16 cattle, 71 horses, 7 sheep/goats, 2 domestic pigs and 1 red deer, amounting to no less than 17,240 kg of meat. Based on these data, we estimate that the number of participants was between 3500 and 5780 persons. Whilst approximate, these numbers allow us to consider some aspects of Scythian economic and political organization, including the high social status of the deceased buried in the Alexandropol and the networks of supply allowing organization of a large number of people and logistics of their food supply.

“ALL MY PRETTY ONES?”— CHEMICAL ANALYSES OF SOME GLASS BEADS FROM EARLY SARMATIAN BURIALS

**Abstract author(s):** Hall, Mark E. (Black Rock Field Office, Bureau of Land Management)

**Abstract format:** Oral

While a variety glass objects are often found in the high status burials of the Eurasian Scythians and Sarmatians, glass beads are commonly found in a variety of female and child burials of varying status belonging to the Sarmatian culture. The purpose of this paper is to present some new, and re-examine some previously published, chemical analyses of glass beads from ten Early Sarmatian (3rd-1st century BC) burials excavated at Pokrovka, Russia. The chemical analyses are classified according to the chemical typologies developed by Lankton and Dussubieux (2006).

Oxide ratio plots indicate 4 groups in the data set; while principal component analysis indicates 4 to 5 groups in the data set. One high lead bearing glass bead is clearly of Chinese origin and does not fit into any of these chemical typologies. There is one bead conforming to a potash glass with moderate lime (mKCA) that has possible origins in Southeast Asia. Eight beads are a soda-lime silica glass made with plant ash (vNC). These types of beads have a wide distribution, and numerous production sites, throughout the East Mediterranean and Central Asia. The largest group of beads correspond to a “Mediterranean” composition. Thirteen of these beads have similar compositions to other Hellenistic glasses from Greece and Anatolia. The remaining six have a composition similar to the Group 2 glasses recovered from Yahorlyk, Ukraine.

The results of the chemical analyses, and the lack of any glass furnaces at Early Sarmatian sites on the steppes, are clear evidence of the economic networks of the Sarmatians. At a minimum, these beads illustrate indirect ties of the Early Sarmatians with the Hellenistic city states and the Maruyan empire.

FALCONRY: FROM THE EURASIAN STEPPE IT CAME AND FROM THERE IT SPREAD

**Abstract author(s):** Grimm, Oliver (Centre for Baltic and Scandinavian Archaeology - ZBSA)

**Abstract format:** Oral

There are good reasons to suggest that falconry, the hunt with trained birds of prey, originally belonged to the Eurasian steppe. The open landscape demanded hunting assistants: dog and golden eagle. Falconry had practical value: acquisition of fur (fox) and

protection of the flock (against wolves). This kind of hunting might be as old as the steppe itself. However, the earliest pieces of evidence – archaeological and written – are c. 2500 years old, for the more eastern part of the steppe.

Much more solid is the source situation for the Chinese Han dynasty; falconry is around 1.900 years old, on the base of archaeological and written testimonies. Somewhat surprisingly, the earliest falconry in Korea and Japan in the east, the Arabian Peninsula and Persia to the south, and Europe and northern Africa to the west is more or less 1500 years old, as indicated, again, by archaeology and written records – how did the knowledge of falconry, once invented in the Eurasian Steppe, travel that far?

WIDENING HORIZONS – CONTRIBUTING TO COMMUNITIES IN A POST-COVID-19 WORLD THROUGH INCREASING ACCESS TO ARCHAEOLOGY AND HERITAGE

**Theme:** 3. The new normality of heritage management and museums in post-Covid times

**Organisers:** Richardson, Philip (Archaeology Scotland) - Doyle, Ian (The Heritage Council)

**Format:** Regular session

We believe that archaeology and heritage is for everyone and that it can have a positive impact on people’s lives and help to develop better communities. With the increasing social-economic impact of the Covid-19 Pandemic bringing into sharp focus the inequalities between many people and communities across the continent there is clear need for fairer, more sustainable and more resilient communities to emerge once the pandemic is over. Community focused archaeology and heritage projects will be one way that we as practitioners can help and contribute to this urgent need.

In this session we will explore the ways in which archaeology and heritage can widen its horizons to help contribute to making our communities fairer, more sustainable and more resilient.

We welcome contributions from members that are engaging in archaeology and heritage practices that are contributing to wider community engagement and development and especially those that are seeking to widen participation to include working with and within communities (communities of place, interest or socio-economic situation) that do not normally have access to archaeology and heritage. We are keen to hear about innovative ways in which different audiences can be engaged in archaeology and heritage, and of new methodologies for widening participation and positively contributing to different communities. We would also welcome contributions from those members whose projects or initiatives did not work as envisaged or planned as well as contributions that critically assess the roles in which archaeology and heritage can contribute to wider socio-economic problems.

ABSTRACTS:

RECHARGING PUBLIC PARTICIPATION IN ARCHAEOLOGY: THE CBA’S RESPONSE TO COVID-19

**Abstract author(s):** Corkill, Claire - Redfern, Neil (Council for British Archaeology)

**Abstract format:** Oral

The impact of Covid-19 on local archaeology groups and societies has been profound, with activities restricted and many groups lacking the skills and confidence to engage with their members successfully online. The potential long-term impact of this remains to be seen but we know that many groups are concerned about their lack of income, ability to rebound and the effect that their limited engagement is having on their members. While the focus of these groups is the delivery of archaeology-based activities, many of them also play a significant role in people’s lives creating wellbeing opportunities.

During 2020 the CBA undertook a range of activities to support local archaeology societies through the pandemic as part of our Historic England funded Recharging British Archaeology project. This allowed us to provide some immediate assistance and look at opportunities to help groups become more resilient for the future through new methods of engagement.

The Festival of Archaeology also provided valuable learning opportunities. Moving from on the ground to digital resulted in a significant drop in participation from local groups but also highlighted the potential digital events offer to reach new audiences and engage people in different ways.

Moving beyond the pandemic our paper will set out how we are looking to take these experiences and continue to work with groups and societies to develop creative, engaging ways to use archaeology to help people explore the stories of their local place and feel more connected to their communities.

A ROMAN VISITOR CENTRE FOR MENTAL WELLBEING

**Abstract author(s):** van den Dries, Monique (Faculty of Archaeology, Leiden University) - Hazenberg, Tom (Hazenberg Archeologie)

**Abstract format:** Oral

In this paper we will talk about a care centre for (around 500) people with mental disorders (like Down Syndrome, dementia etc.) in the Netherlands (Ipse de Bruggen). During its construction in the 1970’s, a Roman fort and harbour was discovered, including six ‘Zwammerdam ships’. This Roman history inspired the organisation to open a Roman visitor centre (in 2016). The care centre aimed to use its heritage to achieve a ‘reversed integration’ of clients with ordinary citizens, by encouraging local villagers and tourists to

visit the Roman exhibition. Clients of the care centre helped making the visitor centre and some of their day time activities are still inspired by the heritage and the tasks needed to run the visitor centre. As this is a unique use of Dutch heritage, the authors conducted a study among the clients (and staff members) to learn about the effects of the visitor centre on their wellbeing. This paper will discuss the results of this evaluation.

### 3 COMMUNITY-LED SURVEYS OF IRISH HISTORIC GRAVEYARDS DURING THE COVID-19 PANDEMIC

**Abstract author(s):** Tierney, John (Eachtra)

**Abstract format:** Oral

Archaeological fieldwork since March 2020 has presented some interesting challenges and responses by our own team and by our community group partners.

Due to Covid-19 restrictions;

1. we seem to have ended up with more rapid data capture, albeit with some impacts on quality in the initial phase of data entry.
2. An older cohort has taken part in the rural fieldwork ie. anecdotally our usual cohort are mid 50-60s but last Summer (2020) our main drivers were in their 70s? This has resulted in challenges in digital data entry.
3. Our own philosophy has shifted somewhat, probably due to the maturity of the project (10 years old in 2021) to increasing storytelling components rather than the previous emphasis on data gathering.
4. It hasn't happened just yet but we feel like we're going to have more global elements to the storytelling than strictly Irish. Should know by time of the conference if that has materialised ie. you tell the story of Ireland by talking about Irish communities of the diaspora.

### 4 SOFORTHILFEPROGRAMM HEIMATMUSEEN – SMALL SCALE INVESTITION IN RURAL COMMUNITIES

**Abstract author(s):** Civis, Greta (DVA - Deutscher Verband für Archäologie)

**Abstract format:** Oral

The national investition programme „Soforthilfeprogramm Heimatmuseen“ started in spring 2020 during the first lockdown in Germany. Due to this context it was often mixed with programmes meant to limit the harm caused by Covid 19, but it never was: The programme is framed in a national attempt to strengthen rural communities in respects of culture and heritage from pre-covid-times. Small museums, archaeological parks, archaeological sites and similar places were granted up to 25.000€ for investitions to maintain and accompany their work in and with rural communities. The small sums, accompanying guidance by the Deutscher Verband für Archäologie and the option for civil initiatives and volunteers to apply were new for a programme financed by a national ministry. The massive responses showed a grand need for investitions in cultural institutions in rural areas, as well as much appreciation of the national interest and engagement. The presentation will address outcomes and learnings from the first year as well as some perspectives on cultural work in small communities.

### 5 INTERACTING WITH COMMUNITY ARCHAEOLOGY IN A TIME OF PANDEMIC THROUGH VIRTUAL LEARNING ENVIRONMENTS (VLE)

**Abstract author(s):** Donnelly, Colm (School of Geography, Archaeology and Palaeoecology,) - McDermott, Siobhán - Murphy, Eileen (Queen's University Belfast)

**Abstract format:** Oral

The Centre for Community Archaeology at Queen's University Belfast has been developing a series of online learning resources to facilitate increase participation in local heritage across Northern Ireland. Initiated in response to the Covid-19 pandemic and its impact on society, these online learning resources have proven to be highly effective tools to help communities engage with their local archaeological resource, and the current paper outlines the results from two programmes of online learning. The first of these was the Community Archaeology Toolkit (CAT), developed during the Spring 2020 "lock-down" as a means of signposting participants towards a range of freely available online resources while guiding them through archaeological desktop assessment. The paper outlines the results obtained during this initiative and how the CAT enabled individuals in "lock-down" to still engage actively and productively with their heritage using accessible online resources to research their localities. The success of the programme was measured through personal testimonials, anonymous questionnaires and online user analytics. Participants reported increased confidence when engaging with the research process, while their demographic profile proved markedly younger than for a traditional community-based archaeological project. The success of the CAT has now led to the development of a second VLE project, designed for the Lough Erne Landscape Partnership (LELP) in County Fermanagh, and with a wider curriculum that includes oral history collection, building survey, remote sensing and archaeological excavation. With an opening up of social interactions, digital learning was blended with place-based fieldwork experiences.

### 6 CREATION OF AN ARCHAEOLOGICAL EXHIBITION IN PANDEMIC TIMES. THE EXAMPLE OF AMAIUR ARCHAEOLOGICAL CENTRE (NAVARRRE, SPAIN)

**Abstract author(s):** Matelo Mitxelena, Suberri - Errarte Zurutuza, Maite (Aranzadi Science Society)

**Abstract format:** Oral

The archaeological site of Amaiur Castle is located in the homonymous town (Baztan Valley, Navarre, Spain) and it began to be excavated in 2006, owing to the locals initiative. From the first moment, they turned to the Aranzadi Science Society for scientific support. Since then until 2020, excavations have been carried out with volunteers and archaeologists from that Society.

The structures found were musealized in 2014, and the traces found have contributed to strengthen the identity of the town, seeing the site as an indispensable part of the community and a driver in the promotion of tourism. Thanks to this, the town has encouraged a new project that seemed unthinkable in these times of pandemic: an Archaeological Centre with a permanent exhibition where the archaeological items founded in the castle and other historical material are displayed. These pieces are the proof of the battle that took place in the castle in 1512 and the speech and imagery that have been created subsequently about that historical event. Due to the difficulties caused by the epidemic, all this project has been done in a record time of two months.

In this paper the museum designers will explain the process, its strengths and weaknesses, as well as the work that the locals carried out to open this centre in pandemic context.

### 7 COMMUNITY ARCHEOLOGY AND OTHER PARTICIPATORY STRATEGIES DURING PANDEMIC. ADAPTATION AND FUTURE OF THE TERRA LEVIS-MASAV PROJECT, ÁVILA (SPAIN)

**Abstract author(s):** López García, Juan Pablo (MASAV)

**Abstract format:** Oral

In 2017 AC Abulaga was created and linked to it was the Terra Levis Arqueología en Comunidad project. Work processes based on citizen participation in its management, made the project become an action in the territory with the name MASAV -Museo Abierto de las Sierras de Ávila y el Valle Amblés-. A regional management strategy that included research, didactic strategies, culture and communication in a wide territory -Sierra de Ávila and Valle Amblés, Spain-, which was joined by both small town councils, as well as the provincial and regional government. The expectations in 2020 were extraordinary as they would mean the consolidation of the project in the territory. The last big event before the closure of the country due to the Coronavirus was the Archaeological Carnestolendas held on February 29 in Solana de Rioalmar, Ávila, Spain. The attending public was able to enjoy an action-packed day with workshops on experimental archeology, cinema, talks, concerts, and craft markets. COVID-19 was a cloud that was observed on the horizon, but had not yet begun to discharge. On March 14 they confined the country. At stake, a Community Archeology project that had to adapt to survive without the proximity of the community. Without those affections, without that close contact so necessary for a project of this type. The creativity, the desire for action of the countrymen, associates and technicians adapted the strategy to the situation. First with online talks when confinement was more difficult, then with controlled actions in the territory: archaeological excavations, guided tours, artistic interventions ..., which allowed us to achieve the objectives set at the beginning of 2020 and which guarantees, with the support of citizenship and public administration, the survival of this project, at least one more year.

### 8 ARCHAEOLOGY AT THE TRAIN STATION – MAKING A MUSEUM FOR EVERYONE

**Abstract author(s):** Host-Madsen, Lene (Museum Skanderborg)

**Abstract format:** Oral

It will be a completely different experience to wait for a train or bus in the future at Skanderborg Station, Denmark. In 2019, the museum moved into the former post office building at the station with an ambition to create a different museum very close to people's everyday lives.

The ambition is for the museum to become a natural part of the station environment and thus as natural and straightforward to use as public transport.

Imagine that you enter the waiting room on Platform 1, and here you meet the Dead Warriors from Iron Age "Alken Enge", the Viking and his horse from Fregerslev or maybe Princess Anna, who became Queen of England. Or that you follow the archaeologists' fascinating work very closely as they process the material from the excavations in the workshop. You can also take a cup of coffee in the café and experience a pop-up exhibit while you wait.

We put the new museum right where people are. In the middle of the vibrant everyday life. With the location at the station, the museum becomes both a place where you learn about the past and a living meeting place. The ambition is that the physical setting will change the way we think and use museum experiences.

9 **SUSTAINABLE INVESTMENTS FOR MUSEUMS, GALLERIES, AND HERITAGE SITES DUE TO THE CORONA CRISIS**

**Abstract author(s):** Nitzschke, Diana (Deutscher Verband für Archäologie e.V.)

**Abstract format:** Oral

As of september 2020 the Deutscher Verband für Archäologie grants funds to museums, galleries und cultural or archaeological heritage sites within the funding program „Pandemiebedingte Investitionen in Kultureinrichtungen zur Erhaltung und Stärkung der bundesweit bedeutenden Kulturlandschaft“. The program is part of the larger funding program „Neustart Kultur“, brought to life by the BKM, the Representative für culture and media in Germany, due to the Covid-19 pandemic and its impact on cultural institutions.

The cultural institutions can apply for a project between 5000€ and 100.000€. The projects must focus on activities, that strengthen their hygienic conditions compliant with the new normal in living with the Coronavirus and that build up their digital settings and nourish their long-term attractiveness for visitors. Massive responses showed a grand need for invests in cultural institutions, grand or small. The presentation will address outcomes and learnings from the first year as well as some perspectives on cultural work influenced by the Covid-19 pandemic crisis and in times of lockdowns.

10 **PURSUIING TRANSCULTURAL HERITAGE IN THE TIME OF COVID: TOWARDS A MORE ACCESSIBLE ARCHAEOLOGY OF EURASIA IN THE PAST AND PRESENT**

**Abstract author(s):** Knutson, Sara Ann (University of California Berkeley; University of Cologne; University of Warsaw)

**Abstract format:** Oral

In this paper, I explore the possibilities for traditional pieces of archaeological evidence, such as coinage, to contribute to timely discussions in Archaeology and cultural heritage work, especially in light of the COVID-19 pandemic. In particular, the pandemic has demonstrated the importance and relevance of non-invasive, digital methods in Archaeology for examining cultural heritage materials and for using such tools to make these materials more accessible to different communities around the world. My own research uses digital archaeological tools including ArcGIS and Social Network Analysis software to make trans-Eurasian materials such as Abbasid coinage, housed in European museum collections, more accessible to source communities who are the recipients of this heritage. My research in museum collections seeks to understand these archaeological materials as evidence of multicultural networks in the Eurasian past as well as part of contemporary material networks in the 21st century that continue to inform cultural heritage in a variety of ways. In conducting this work, I hope to demonstrate the need for greater sensitivity among researchers to traces of power and inequalities in the past and their entanglement in contemporary public debates and cultural heritage.

11 **(DIS)CONNECTING THROUGH HERITAGE - PERSPECTIVES UPON PRACTICES AIMING FOR SOCIAL COHESION IN NORDIC AND BALTIC MUSEUMS**

**Abstract author(s):** Wollentz, Gustav (The Nordic Centre of Heritage Learning and Creativity)

**Abstract format:** Oral

The paper looks at how heritage can be approached as a process of connecting to diverse communities through focusing upon the concepts of care and belonging. We have also been examining reasons why and when heritage institutions fail in connecting to a diverse audience. We have studied practices and attitudes in museums in Nordic and Baltic countries, through a method of both a widespread questionnaire sent to ca 750 museums in Sweden, Norway, Finland and Estonia, as well as through qualitative semi-structured interviews with a selection of key-individuals. The study was carried out within a larger project called "Heritage, Identity and Social Cohesion", which was collaboration between several museums and other heritage institutions that aimed to develop and pilot activities increasing social cohesion in society. The paper identifies that the current speed of the museum tends to hinder the process of reaching and connecting to a diverse audience, where a relationship based on mutual trust can be sustained over a long period of time. Care is an on-going temporal practice, and there is a danger in placing demarcated beginnings or endings upon it. Furthermore, it identifies the need for a shared understanding within the sector as to what concepts such as diversity mean and how it can be approached through practices in the museum. Finally, the paper recognises that the sector itself has to become more diverse in order to reach out to a plural society.

A. **PARTICIPATORY MUSEUMS: THE STATE OF THE ART OF ITALIAN ARCHAEOLOGICAL MUSEUMS**

**Abstract author(s):** Frascella, Selene (Università Cattolica del Sacro Cuore, Milano)

**Abstract format:** Poster

The COVID-19 pandemic has had its effects on both individuals and museums. While scientific studies have shown the psychological disturbances produced by isolation, research by leading museum associations shows that museums have been quick and proactive in responding to the pandemic and the obligation to close, strengthening their digital activities. These have demonstrated their value, bringing together and comforting people at home, sharing experiences, offering a virtual space to build ideas together.

Now it is important to plan the construction of a new normal, making the new working methods triggered by this crisis systematic. It is important to translate this new digital involvement, which has also made it possible to reach new audiences, into physical and participatory involvement within museums, in anticipation of their reopening. It is time to make the transition to participatory museums, not centred “on” something or designed “for” someone, but created and managed “with” visitors, who can create, share and

connect with each other through content offered. More relevant and interested in people’s needs and interests, they will be able to leverage the high digital engagement achieved during the pandemic, help combat the psychological effects of lockdown isolation, and compensate for the drastic loss of revenue due to forced closure.

In view of this change, it is first necessary to understand what the starting point of museums is in the field of participatory programs in order to be able to design and develop effective strategies. This work fits into this context and will illustrate the state of the art of Italian archaeological museums through a quantitative and qualitative analysis of the participatory projects they have implemented. The goal of the contribution is to analyse, through significant case studies, to what extent Italian archaeological museums have reached the standards of public participation and through which forms.

295 **BEYOND THE FAR HORIZON: EVALUATING REGIONAL SURVEY IN THE WESTERN IBERIAN PENINSULA. THE STATE-OF-THE-ART AND FUTURE PROSPECTS (FIDO; ARCHAEOLOGICAL PROSPECTION)**

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** García Sánchez, Jesús (CSIC-Instituto de Arqueología,Mérida) - Devi, Taelman (Ghent University) - Paul S., Johnson (University of Nottingham)

**Format:** Regular session

Regional landscape surveys in the Mediterranean have been widely employed since the1980 s, with the seminal article by John Bintliff and Anthony Snodgrass (1988) continuing to provide a methodological and conceptual underpinning to many current projects. Despite this prevalence, projects have often focussed on historically important sites, or otherwise easily accessible landscapes; marginal landscapes and those on the periphery of historically attested polities remain understudied.

This session aims to address some of these lacunae through a focus on one such liminal zone, the western Iberian Peninsula. Despite a strong tradition of recording rural archaeological sites, often resulting in municipal site-catalogues, and in studies centred on the hinterlands of ancient cities, there is little current engagement in western Iberia with emerging trends in survey methodologies. We therefore aim to address the following specific questions: how can challenging landscapes such as the dehesa and mountainous regions be approached archaeologically; how might industrial agricultural landscapes be harnessed for their archaeological potential, and how can archaeological resources be understood and preserved; what are the current links between western Iberian surveys and projects elsewhere in the Mediterranean, and how have survey methodologies in these marginal landscapes been tailored to specific archaeological and historical goals and aims?

From this focus, we aim to widen the horizons of discourse on landscape studies, relying on methodological and theoretical insights from this, and other regions, to develop a discussion around how to engage with key socio-cultural questions about identity, the exploitation of landscape and its sustainability.

Since different national research traditions encourage a variety of theoretical and methodological approaches, we welcome proposals from colleagues which apply a landscape archaeology perspective to surveys dealing with Western Iberia, and also papers concerning other Mediterranean zones.

Bintliff, J., Snodgrass, A., 1988. Mediterranean survey and the city. *Antiquity* 62, 57–71.

**ABSTRACTS:**

1 **BEYOND THE FAR HORIZON: EVALUATING REGIONAL SURVEY IN THE WESTERN IBERIAN PENINSULA**

**Abstract author(s):** Johnson, Paul (University of Nottingham) - Taelman, Devi (Ghent University)

**Abstract format:** Oral

Regional landscape surveys in the Mediterranean have been widely employed since the1980’s, with the seminal article by John Bintliff and Anthony Snodgrass (1988) and the volume by Johnson and Millett (2013) continuing to provide a methodological and conceptual underpinning to many current projects. Archaeological survey projects, however, generally still focus on historically important sites and/or easily accessible landscapes.

In this introductory paper, we present ongoing research of a rural and landscape survey in the north-western Alentejo region in Portugal and western Extremadura region in Spain that aims to address questions about the impact and causes of ecological change over the long dureé, alongside changes in political authority, through a study of settlement dynamics and the conceptual geographies which they signify, in a remote part of the Roman Empire and in a particular survey-challenging dehesa landscape.

Through this case study, we wish to introduce some critical issues around the selection of survey areas, the development of survey strategies and methodologies, and the need for well-defined and clearly articulated research questions when investigating so-called ‘hidden’ landscapes and/or landscapes on the periphery of historically attested polities. These issues form the conceptual core of this session raising questions which will be explored through a set of papers which combine assessments of the latest developments in Mediterranean survey archaeology (methodologically, strategically and analytically), with case-studies of landscape surveys in different parts of the western Iberian Peninsula, that articulate these developments to go beyond the established archaeological traditions of the region.

## 2 BEYOND THE PLOUGHED SURFACE: DEALING WITH VISIBILITY AND ACCESSIBILITY BIASES

**Abstract author(s):** van Leusen, Martijn (Groningen Institute of Archaeology)

**Abstract format:** Oral

Survey archaeologists have long been aware of the dangers inherent in the selection of 'best' areas to survey, i.e. those that are most easily accessible and present little or no obstructions to the documentation of surface archaeology. They have attempted to counteract the resulting biases by paying attention to the regional sampling design and by adapting the field protocols, but have achieved only partial success in this. More recently, some projects have taken to specific targeting of 'difficult' landscape types – mountainous, marshy, uncultivated, buried. This paper examines what we can learn in this respect from the 'Hidden Landscapes' surveys conducted between 2005 and 2013 by the Groningen Institute of Archaeology in central and southern Italy, and looks at potential future developments. Where possible and relevant, the discussion will refer to the recently published multi-authored "Guide to good practice in Mediterranean surface survey projects" (Journal of Greek Archaeology vol. 5, 2020).

## 3 THINKING THROUGH "MARGINAL" LANDSCAPES IN THE MEDITERRANEAN: A CASE STUDY FROM SW TURKEY

**Abstract author(s):** Vandam, Ralf (KU Leuven; Vrije Universiteit Brussel)

**Abstract format:** Oral

This paper focuses on several themes with regard to marginal landscapes in the Mediterranean such as connectivity, vulnerability and resilience and applies it to the case study of the Dereköy Highlands in SW Turkey. Previous archaeological research in the area and generally in Western Turkey has until now mainly focused on the larger fertile lowland areas (e.g. Burdur Plain). This research revealed numerous farming settlements from the Neolithic (6500 BC) onwards and illustrated clear distinctive periods of continuity and collapse in human occupation in these areas. Next to nothing was known about sites in other landscape units such as remote, high altitude locations, which in contrast to plain areas, are traditionally considered to be 'marginal', as they are not particularly favorable for permanent habitation. The Sagalassos Archaeological Research Project started a new archaeological survey research in the Western extent of the Taurus mountainous which aims to fill the gap in knowledge by documenting all human activity in the so-called 'marginal' landscapes. With this research we aim to investigate how communities operated in these landscapes in terms of subsistence, resource exploitation and mobility and to assess how different/similar they were in comparison to the city of Sagalassos and the lowland communities. In this paper we will illustrate that marginal landscapes should be considered as integral parts of the cultural landscape. From early onwards (120.000 BCE) until recent times (Late Ottoman period; 18th - 19th century) we have evidence that people were living and exploiting these landscapes and that they formed an explicit element in the different lifeways and economic systems of past communities.

## 4 AN INTERDISCIPLINARY, COMPARATIVE APPROACH TO NON-INVASIVE ARCHAEOLOGY ON THE TIDAL ZONE AND MARSHLANDS OF LACUS LIGUSTINUS. THEORETICAL APPROACH AND METHODS

**Abstract author(s):** Lagóstena, Lázaro (Universidad de Cádiz) - Aragón Nuñez, Enrique (Flinders Univesity)

**Abstract format:** Oral

Over the last few decades, archaeologists have identified patterns and created models of early human migration and mobility based on evidence recovered from sites on land. However growing awareness of past climate change, and sea-level fluctuations have highlighted a critical flaw in these models. Although archaeologists commonly point to the importance of coastal and riverine margins in migration studies, they still not been investigated systematically. Marshlands play a pivotal role in the understanding highly altered landscapes that based on their use and perception from different societies make them be considered marginal. Marshlands archaeology investigations can seem overwhelming, given their extension. Still, the increasing availability of non-invasive technology had opened the opportunity to access archaeological sites in spaces that occupies vast areas. This context has enabled the discipline to blossom, primarily through geoarchaeological and remote sensing methodologies. This paper purports to propose methods applied to marshland site prediction and detection, for an adaptation on a specific case of study, the lower course of the Guadalquivir riverbank (Cadiz, Spain), as representative of the so called lacus Ligustinus, within the incorporation of local and traditional knowledge. Ultimately, this paper's main objective is to introduce the theoretical and practical framework to address research questions surrounding this particular territory of the Southwest of the Iberian Peninsula.

## 5 WHEN THE GOING GETS TOUGH: RESOURCE PACKAGES AND SUSTAINABLE LANDSCAPE MANAGEMENT IN SPHAKIA, CRETE

**Abstract author(s):** Nixon, Lucia (Wolfson College, Oxford)

**Abstract format:** Oral

The Sphakia Survey, co-directed by Nixon and Moody, is an archaeological project investigating human activity in this rugged ('tough') peripheral area, from people's arrival (later 4th millennium BC) to the end of Ottoman rule (1898).

The concept of resource packages was developed (Nixon 2006) to assess land use in Sphakia. A resource package (RP) is a combination of perceived resources in a specific area, which people use in a specific way at a specific time.

People in Sphakia tended to live in more or less sedentary agro-pastoral communities. Each settlement had a minimum local RP including arable, pasturage, water procurement, and connectivities (in/visibility, inter/visibility of specific locations; networks inside/outside Sphakia, by land and sea). People also used other RPs, often some distance from settlements, and sometimes at a significantly different altitude. The clearest example is the high pastures in the White Mountains, several hours' walk from relevant settlements, exploited in particular by herders over the Survey's whole timespan, and into the present. Specific high pasture locations were used repeatedly, though not necessarily continuously, by people living elsewhere. In Venetian-Turkish times, textual evidence confirms that shepherds produced enough cheese to sell outside Sphakia (as today).

Re-use of the same areas does not indicate identical agro-pastoral systems over time. Rather, it suggests that land where something will grow without cultivation is never marginal. Careful use of all Sphakiote RPs is crucial. Modern parallels suggest that people know the consequences of failures in resource management (Forbes 2017). In this case, over-grazing could not be permitted, because its adverse effects on arable were well-known. The details of RP use and the systems of which they are a part will differ from period to period, but any system needed built-in sustainability. Sustainability therefore underlay people's resource strategies, and their tactical use of individual RPs.

## 6 UNLOCKING THE LEGACY SURVEY DATA OF ROMAN PORTUGAL

**Abstract author(s):** Casarotto, Anita (Leiden University; Royal Netherlands Institute in Rome - KNIR)

**Abstract format:** Oral

In this paper I present a data collection initiative and a digital platform that allows scholars and students who conducted regional landscape surveys in the Western Iberian Peninsula to publish online their survey projects and share their data. This initiative is part of a Leiden University project funded by the Dutch Prins Bernhard Cultural Foundation that aims at studying settlement patterns in relation to the Roman expansion in ancient Lusitania (Portugal – western Iberian Peninsula, 3rd c. BC to the 3rd c. AD), and to compare it to other Mediterranean data-sets (esp. in Italy). Activating researchers and students, these legacy survey data can be unlocked and made openly accessible online by means of a digital webGIS platform. In this paper the results of an online internship are presented in which students collected and digitized a good sample of legacy data from regional surveys in Portugal, and assisted the researchers working there with their data publication in the Fasti Online Survey platform. The increased availability of open survey data expected if wider participation in this initiative is achieved will enable comparison of data patterns and survey methodologies on an inter-regional level, which is vital for landscape archaeological analysis and historical reconstruction.

## 7 RESILIENCE AND ROMANIZATION, UNDERSTANDING THE LATE IRON AGE AND EARLY ROMAN COUNTRYSIDE IN LUSITANIA

**Abstract author(s):** García Sánchez, Jesús (CSIC-Instituto de Arqueología, Mérida)

**Abstract format:** Oral

In 2019 a new research project was established to study the Late Iron Age landscape and the transition to the Roman organized territory of Augusta Emerita, capital of Lusitania (present-day Mérida, Badajoz). This paper aims to introduce the main debate about the organization of the western territory of Augusta Emerita with a special interest in the social dynamics occurring in the area from the Late Republican/ Iron Age period to the creation of a Roman organized landscape. These dynamics could be traced in archaeological proxies such as the settlement pattern, the organization of society in new clustered sites rather than fortified hillforts, and other historical information, such as epigraphic formulae.

Methodologically speaking, this paper will discuss the geospatial (site pattern analysis, remote sensing) and fieldwork approaches, namely intensive field survey conducted in early autumn 2020, and will try to frame the discussed topic in a wider Mediterranean and Iberian context in opposition to old-fashion regional approaches which still dominate the local literature.

## 8 ARCHEOLOGY BETWEEN VINEYARDS. ARCHAEOLOGICAL SURVEYS IN TIERRA DE BARROS (EXTREMADURA, SW OF SPAIN)

**Abstract author(s):** Pérez-Aguilar, Luis-Gethsemaní (Archaeology Institute of Mérida - CSIC) - Gordillo Salguero, David (University of Salamanca)

**Abstract format:** Oral

The historical importance of the current region of Tierra de Barros is widely acknowledge. This zone, characterized by the fertility of its lands, nowadays oriented towards viticulture, used to be one of the most relevant areas of Colonia Augusta Emerita's territory.

Ancient settlement patterns in Tierra de Barros are known after the datasets provided by the archaeological surveys carried out in the 1980s. These works represented a break through and their advances constitute the starting point for further research. Nevertheless, this data has important downsides.

In June 2020, we started a new campaign of archaeological field survey in this area within the project "Settlements and landscape in Tierra de Barros (Extremadura) between Protohistory and the Early Middle Ages". Our main purpose is to refresh the existing information in the central part of the Tierra de Barros.

9 The two year duration of the project forced us to adapt methodological approaches and the main goals to the available resources. Firstly, we do site-oriented macro-scale surveys with a threefold aim. To locate and correctly georeferenced both known and new archaeological sites; to refine the chronological information of such sites based on ceramological criteria, and to determine the functionalities of these archaeological sites. To do so, we apply parameters such as presence/absence of diagnostic artifacts as well as the location and extension of sites.

A second phase consists on intensive micro-scale surveys in selected archaeological sites. This approach combines artifact collection (for chronological and functional information), and spatial data to produce kernel density estimations. This allows us to perform quantitative analyses such as the calculation of settlement’s entropy. Eventually, these analyses will provide an insight into the exosomatic metabolism of the community that occupied the studied sites.

9 THE LANDSCAPE AS A LABORATORY. THE CASE OF CIUITAS IGAEDITANORUM IN THE NORTHERN HINTERLAND OF LUSITANIA

**Abstract author(s):** Lacerda, Sofia (University of Coimbra; Centre of 20th Century Interdisciplinary Studies)

**Abstract format:** Oral

During the Roman period, the historic village of Idanha-a-Velha was a small but important town called Igaedis. Located in the northern hinterland of Lusitania, at a strategic location within the province, the ciuitas Igaeditanorum included a large territory and an economy based on gold mining and agricultural production. Today, most of this territory belongs, broadly, to the district of Castelo Branco, in the interior of Portugal. Over the last decades, several archaeological surveys and excavations have been done, thus helping us to better understand this ciuitas: the singular contours of its city, the kind of rural settlements who Romans established here or the specificities of its economy. Recently, through various spatial analyses, we tried to represent and connect the data collected during field work. With this in mind, our aim is to spread the results of these spatial analyses, showing how they express the occupation and exploitation of the ciuitas Igaeditanorum during the Roman period.

10 A GIS BASED LANDSCAPE STUDY IN LATE IRON AGE BETWEEN THE BASIN OF RIVER LEÇA AND LOWER AVE (NORTHWEST PORTUGAL)

**Abstract author(s):** Maciel, Sílvia (Independent researcher) - Blanco-Rotea, Rebeca (University of Santiago de Compostela)

**Abstract format:** Oral

Martins Sarmento’s pioneer work in the nineteenth century in the hillfort of Citânia de Briteiros (Guimarães, Portugal) was the starting point of Iron Age studies in the Northwest of Portugal. Many researchers continued his work alongside theoretical and methodological advances, focusing on developing site-catalogue studies or on identifying Iron Age settlement patterns in the main hydrographic basins, in relation to the strategies of municipal territory reorganization carried out in the 1980s, but few landscape studies were carried out since then. In the last decade, Geographic Information Systems have been an important tool for noninvasive studies of Iron Age landscape but also for heritage representation and preservation by contributing for the knowledge about these sites that, in some cases, were intervened at that time and by identifying new settlements from the same period completing the settlement structure and improving the settlement patterns. In our opinion, the lack of investment in cultural heritage in Portugal and the difficulty of preserving/maintaining the sites post excavation has led to a certain standstill in this line of research, which has only been recovering in recent years due to various researchers that have been incorporating new technologies.

With this paper, we aim to present the Landscape study of Late Iron Age settlements between de river Leça and the lower Ave through geospatial tools. Our main goal was to understand the relationships between sites and its surroundings and inter-sites, with the oppidum of Citânia de Sanfins (Paços de Ferreira, Portugal) as a focal point. We combined an Information System 2Archls (Unity of Archaeology of University of Minho) with GIS, to obtain important locational information such as mobility, accessibility, and visibility that were validated in the field. Also, we intend to ponder about new lines of work that combine the use of new technologies with surface survey tools.

11 MODELIZATION OF THE ROMAN SETTLEMENT IN NORTH ALENTEJO (PORTUGAL) USING LEGACY DATA, ITINERARIES, SURVEYOR’S LITERATURE AND AGRICULTURAL RESOURCES

**Abstract author(s):** Trapero Fernández, Pedro (Cádiz University) - Carneiro, André (Évora University)

**Abstract format:** Oral

Our aim is to use Geographical Informations Systems to propose a method to classify and study the limits and connections between villae and their fundi in Alto Alentejo (Portugal). This territory has scarce urban centers, such as Ammaia and Ebora, being not easy to determine what the association of villa with cities is, but has relevant connections between the main urban centers Emerita Augusta and Olisipo by the XII, XIV, and XV main roads. This territory benefited from some archaeological research, allowing us to develop our methodology, which consists of associating current geographic parameters with recognizable values in the recommendations in the ancient surveyor’s and agronomist literature to determine the limits between the different agricultural fundi. Also, we want to use geographical data to try to evaluate the agricultural potentiality in the land use to test and propose a methodological model to analyze the roman settlements combining the existing data.

12 A LIMITED HORIZON IN CENTRAL PORTUGAL: AN OVERVIEW AND FUTURE PROSPECTS FOR REGIONAL ARCHAEOLOGICAL SURVEY IN THE REGION OF AVEIRO

**Abstract author(s):** Vilarinho, Gil (The University of Edinburgh)

**Abstract format:** Oral

The region of Aveiro, in central Portugal, could be considered a strange case in archaeological terms, as a relatively small number of sites have been documented hitherto across this territory. When compared to other regions in Portugal, the constrast in the number of sites identified in this littoral area becomes even more evident. For decades, this absence of evidence was frequently associated with the recent formation of this stretch of coastline but a simple spatial analysis reveals that the mountainous areas, which are distant from the shorelire, also lack known archaeological evidence. Why are there fewer sites known in this region then? The answer is simple: Though there is a long tradition of work at known archaeological sites, field surveys and landscape analysis have been frequently overlooked until now.

Building on an on-going research on the Iron Age and Roman settlement of this region and drawing on literary sources, recent publications, LiDAR and geophysical data, this paper aims to present an overview of the data currently available for region of Aveiro and discuss the problematics for regional surveys in this area, as well as future prospects. The geomorphology of this landscape is diverse and includes vast littoral plains with holocene formations and high mountain ranges. This broad case study area offers different perspectives for archaeological prospection and different problems. In this study we argue that, although the lack of archaeological survey is common throughout the whole area, the problematics and the future prospects vary according to topography, demographics and land-use. Ultimately, this paper asserts the need for further archaeological investigation and provides some valuable insights for future research.

296 TRACING PREHISTORIC HUNTER-GATHERERS IN THEIR ENVIRONMENT: CHALLENGES AND PERSPECTIVES FOR PROSPECTING ELUSIVE LIFEWAYS (PAM; ARCHAEOLOGICAL PROSPECTION)

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** De Smedt, Philippe (Department of Environment, Ghent University; Department of Archaeology, Ghent University) - Corradini, Erica (Institute of Geosciences, Applied Geophysics, University of Kiel) - Schneidhofer, Petra (Department for Cultural Heritage Management, Vestfold and Telemark County Council) - Verhegge, Jeroen (Department of Archaeology, Ghent University; Department of Environment, Ghent University; GATE Archaeology)

**Format:** Regular session

While advances in survey methods have been a boon for studying past landscapes, mapping traces of hunter-gatherers and their environment remains a long-standing challenge. Information on such lifeways, characterised by ephemeral land-use, is difficult to capture with any survey approach, particularly in stratified environments. This elusiveness is exacerbated when using non-invasive tools (such as geophysics or remote sensing), and strongly restricts identifying and characterising land-use patterns hidden in landscape-scale datasets.

The continually expanding archaeological prospection toolkit does, however, create new opportunities. Recent, well-structured integrated approaches show how accounting for the limitations of complementary survey methods as well as for the intricacies of the prehistoric record supports detailed palaeoenvironmental reconstructions, and can equally provide fine-grained site-specific insight into cultural activities. Still, such advances remain only peripherally integrated into Palaeolithic or Mesolithic archaeology, with particular consequences for development-led applications. While available survey toolkits have promise, their translation into daily practice remains variable, restricting the potential of ‘Malta archaeology’ for tapping into this archaeological resource. Although in some regions, finetuning prospection strategies has increased the amount of detected stone age sites, in other areas this number has stagnated or – e.g. following intensified farming practices – deteriorated.

In this session, we strive to bridge the gap between fundamental questions related to Palaeolithic and Mesolithic archaeology, and established and novel survey approaches. We consider the contribution of archaeological prospection in its broadest sense: ranging from non-invasive techniques (e.g. remote sensing and geophysics), to minimally (borehole and direct-push) and highly invasive (test pitting) methods, complemented with spatial sampling strategies tailored to Palaeolithic and Mesolithic targets.

We welcome contributions on questions and solutions to the complexities of prospecting hunter-gatherer environments, and equally encourage discussing integrated survey approaches that combine traditional and emerging methods to investigate elusive types of the wider array of prehistoric land-use.

ABSTRACTS:

1 DETECTING MESOLITHIC SITES. A MULTICHANNEL GROUND PENETRATING RADAR (GPR) INVESTIGATION AT ANCIENT LAKE DUVENSEE

**Abstract author(s):** Corradini, Erica (Institute of Geosciences, Christian-Albrechts-University Kiel) - Groß, Daniel (Centre for Baltic and Scandinavian Archaeology - ZBSA, Schleswig-Holstein State Museums Foundation Schloss Gottorf) - Wunderlich, Tina (Institute of Geosciences, Christian-Albrechts-University Kiel) - Lübke, Harald (Centre for Baltic and Scandinavian Archaeology - ZBSA, Schleswig-Holstein State Museums Foundation Schloss Gottorf) - Wilken, Dennis - Erkul, Ercan (Institute of Geosciences, Christian-Albrechts-University Kiel) - Schmölcke, Ulrich (Centre for Baltic and Scandinavian Archaeology - ZBSA, Schleswig-Holstein State Museums Foundation Schloss Gottorf) - Rabbel, Wolfgang (Institute of Geosciences, Christian-Albrechts-University Kiel)

**Abstract format:** Oral

A large-scale ground penetrating radar (GPR) survey using a 16 channel MALÅ Imaging Radar Array (MIRA) system was performed at the early Mesolithic hunter-gatherer sites of Duvensee (10000-6500 cal. BCE). The aim was to map the location of former islands possibly hosting Mesolithic camps, for reconstructing the prehistoric landscape and shed light on human-environment interaction in the Early Holocene. The presented study extends the geophysical work done in the past four years investigating the unknown area surrounding the recently excavated site (WP10) and eventually detect new islands which can be a location for yet unknown dwelling sites. Furthermore, a detailed comparison between the archaeological excavation and the GPR record is presented with the purpose to identify hazelnuts roasting facilities, which are the most important findings of the camps. It turned out that the detection of these features is possible, but this demands a very detailed analysis of the different profiles and is partly only possible with prior archaeological identification. Nevertheless, the stratigraphy was imaged with a high degree of resolution (3/5 cm) providing the internal layering of the archaeologically investigated sectors and delivering the possibility to locate the interface between archaeological relevant layers and the sterile ones.

Another striking discovery is the presence of unknown islands, promising more insights into prehistoric life in the area. However, currently no evidence of surface findings that would indicate human occupation is recorded. Integrating non-destructive but high-performance analysis into archaeological landscape reconstruction has proven useful in several cases. However, applying this to elusive archaeological landscapes like ancient Lake Duvensee where hunter-gatherers left little structural evidence of their activities is significantly improving our understanding of the past. Apart from being able to cover large areas in a short time, the GPR measurements need adequate post-processing to reach useful results and calibration through in situ investigations.

2 A NEEDLE IN A HAYSTACK. LOOKING FOR TRACES OF PALEOLITHIC HUNTER-GATHERERS IN THE WESTERN TAURUS MOUNTAINS (SW, TURKEY)

**Abstract author(s):** Vandam, Ralf (KU Leuven; Vrije Universiteit Brussel) - Van Peer, Philip (KU Leuven) - Willett, Patrick (KU Leuven, Belgium; University at Buffalo, SUNY) - Egberts, Ella (The British Museum) - Poblome, Jeroen (KU Leuven)

**Abstract format:** Oral

In 2016-2017, the Sagalassos Archaeological Research Project initiated an archaeological intensive field walking survey program in the Dereköy Highlands, SW Turkey. This survey investigated the long-term socio-ecological developments in agriculturally "marginal" highlands within our mountainous study region in order to break with the traditional archaeological research focus on ecological zones that are well-suited for crop cultivation, such as valleys and plains. One of the most remarkable outcomes of Dereköy Highlands survey was the discovery of Middle Paleolithic artefacts (120 000-45 000 BCE) which push the evidence of the earliest human activity in the area far back in time. After more than 25 years of archaeological surveying in the research area, we were finally able to detect solid indications of Middle Paleolithic human activity in the form of abundant loose finds, but more importantly in two concentrations on a high plateau within the Bey Dağları as well. This plateau is characterized by an extensive gully system that has been transecting sedimentary (probably aeolian and fluvatile) deposits. Although no Middle Paleolithic artefacts were yet identified in-situ, it is most likely that these artefacts have been eroded from buried sedimentary deposits that are being washed out through the active gully system. In 2021, we will initiate invasive test pitting survey research within this plateau to hopefully gain high resolution data on the chronology and nature of the artefact concentrations. The prospect of finding Middle Paleolithic in-situ occupations in what seems to be a large sedimentary trap indicates that this site has major potential for the study of the Paleolithic past of Anatolia. In this paper we will specifically present our survey design along with our first results and compare it to previous survey research which had yielded so very scarce Paleolithic results.

3 DETECTING SEALED FINAL PALEOLITHIC HUNTER-GATHERER SITES IN THE SCHELDT VALLEY (INW BELGIUM) – AN INTEGRATED APPROACH

**Abstract author(s):** Pincé, Possum (Department of Archaeology, Ghent University) - Vandenberghe, Dimitri - Karimi Moayed, Nasrin - De Grave, Johan (Department of Geology, Ghent University) - Crombé, Philippe (Department of Archaeology, Ghent University)

**Abstract format:** Oral

During the Late Glacial recolonization of NW Europe, hunter-gatherers preferably settled in sheltered environments and along river valleys and lake edges. In the Scheldt valley of NW Belgium, however, remains of these Late Glacial settlers are scarce. It is at pres-

ent not clear whether this scarcity is related to specific taphonomic factors and/or corresponds to a prehistoric reality. Moreover, the few known sites in the Scheldt floodplain all seem to belong to the Younger Dryas (final stage of the Late Glacial), which led to the recent hypothesis of a possible population shift from the inland lakes towards the Scheldt River at the abrupt transition from the warm Allerød to the extreme cold Younger Dryas. This hypothesis, however, is significantly hampered by the lack of an in-depth assessment of Final Palaeolithic sites in the Scheldt valley.

To investigate this apparent scarcity, geoarchaeological research is performed on elevated locations (aeolian dunes) along the floodplain of the Scheldt River and its tributaries that have a high potential for sealed Final Palaeolithic sites. The first step of this research is to reconstruct the formation and age of these dunes by using minimally (manual and mechanical coring) and highly (test-pitting) invasive survey techniques that include sampling for sedimentological analyses (e.g. granulometry, soil micromorphology) and Optically Stimulated Luminescence (OSL) dating. Based on these results, systematic archaeological coring surveys are conducted on a selection of these dunes to detect sealed Final Palaeolithic sites and to obtain a better understanding of the hunter-gatherer responses to the changing environment and climate in NW Belgium during the Late Glacial. This paper will present the first results, new insights and challenges of this research project.

4 KOKOŘÍNSKO: ASSESSING PROSPECTION DATA ON HUNTER-GATHERER LIFEWAYS FROM A VARIABLE ENVIRONMENT

**Abstract author(s):** Kapustka, Katarína (Institute of Archaeology of the Czech Academy of Sciences, Prague, v.v.i.) - Walls, Matthew (University of Calgary) - Pauknerová, Karolína (Center for Theoretical Study, Charles University)

**Abstract format:** Oral

There are many modes of archaeological prospection, and scrutinizing the character of how spatial data is produced is critical to understanding how past communities disposed themselves on past landscapes. This is particularly the case for highly mobile hunter-gatherers whose lifeways include movement across environments that have variability in terms of preservation conditions. In this paper we present preliminary results of a structured survey project that we conducted in the region of Kokořínsko in order to better understand human-environment relationships during the Pleistocene/Holocene transition of Central Bohemia. An objective was to locate both surface scatters and well-stratified contexts with large assemblages that might offer clear insight on lifeways during the radical environmental changes that took place during the Pleistocene/Holocene transition. Kokořínsko is comprised of deeply incised sandstone valleys that break up high plateaus; this creates a rich and varied environment with a dense distribution of ecological niches and localized contexts where geomorphological conditions support archaeological preservation. Our sampling strategy included a combination of field walking, sub surface boring, and test pits, adapted to local context. We outline the distributions of sites located during this work, and reflect critically on the extent to which these reflect real land use patterns through the Final Paleolithic and Mesolithic communities can be assessed, or if these are products of the sampling strategy.

5 PRECISE SUBMARINE MEASUREMENT AS BACKBONE FOR THE RECONSTRUCTION OF COASTAL MESOLITHIC LANDSCAPES

**Abstract author(s):** Enzmann, Jonas (Lower Saxony Institute for Historical Coastal Research)

**Abstract format:** Oral

Since 2011 the site Strande LA 163, in 6 m depth around 1 km in front of the modern coast, is known as one of the few aceramic Ertebølle sites in Northern Germany. A first excavation campaign in 2012 and a survey in 2014 had very promising results, which led to the current project. Under the title: „Subsistence strategies, settlement structure and communication during the terminal Mesolithic exemplified by a submarine micro region in the Bay of Kiel“ the German Research Foundation (DFG) granted a three years project to the Lower Saxony Institute for Historical Coastal Research (NIHK).

The presentation will show how it was possible to reconstruct the palaeotopography and the complex site formation processes. During the project several small trenches were excavated. These trenches were supplemented by coring transects made with a Pürckhauer and special sampling cores next to the trenches obtained by a vibrocoring device. All coring had to be done by divers due to the exposed position of the site. Special remarks will be made on the innovative measurement system which was crucial for the merging of small-scale excavation data, the mid-level coring data and the large scale seismic and sonar data. By combining Computer Vision Photogrammetry with Total Station measurements, it was possible to get positions of layers, artefacts, coring's and samples with a precision of under 5 cm and even less in height. Obviously such a precise and coherent localization of different datasets and information is necessary to understand the extremely dynamic ancient coastal landscapes in which hunter-gatherers lived.

6 DIRECT PUSH VIDEO IMAGING FOR PREHISTORIC PALEOLANDSCAPE MAPPING

**Abstract author(s):** Verhegge, Jeroen (Department of Archaeology, Ghent University; Department of Environment, Faculty of Bioscience Engineering, Ghent University) - Delvoie, Simon (Department of Architecture, Geology, Environment and Civil Engineering, University of Liège) - Luong, Hiep (Department of Telecommunications and Information Processing, Faculty of Engineering and Architecture, Ghent University)

**Abstract format:** Oral

Prospecting prehistoric landscapes relies profoundly on natural paleolandscape surveys. Invasive sampling methods, such as test pitting and coring, are widely used but rely on a direct soil or sediment observations. Non-invasive, sensor based techniques such

as remote sensing, marine or near-surface geophysical survey were introduced over the past decades. Direct-push sensing is used less frequently and forms a compromise of both approaches, due to its rapid, in-situ data recording. Since, the sensor is pushed down the soil profile while recording data continuously, the target discrimination potential is independent of the burial depth, contrary to non-invasive survey, but dependent on the horizontal extent instead. Therefore, it is well-suited to map deeply buried, subtly contrasting targets with a large horizontal extent and a complex overburden.

After investigating electrical cone penetration testing in combination with electrical conductivity logging, the potential contribution of direct push, in-situ video imaging was explored over the past years to map prehistoric paleolandscapes of the polder-, sand- and loess region of Belgium. On different locations, 720i videos of the soil passing by a small sapphire glass window were recorded as a conus containing the camera is pushed into the soil. Next, image stitching was employed to convert the recorded video (frames) and time-depth data to a vertical mosaicked overview image of the individual depth soundings. This results in an ca. 1 cm wide RGB image of the penetrated soil profile, which was interpreted in combination with mechanical and electrical soil properties. Results point towards an increased discrimination potential in organic (rich) sediments and subtle paleosol horizons. As such, direct push camera imaging forms a considerable new tool for prehistoric landscape mapping. Nevertheless, independent validation of the interpretations by direct soil observations is still required. Further improvements in camera resolution and color calibration could reduce this dependency.

**COMPLEX REALITIES OF HUNTER-GATHERER ARCHAEOLOGY: A REVIEW OF PAST ADVANCES AND FUTURE CHALLENGES FOR MAPPING ELUSIVE LIFEWAYS**

**Abstract author(s):** De Smedt, Philippe (Ghent University) - Corradini, Erica (Institute of Geosciences, Applied Geophysics, University of Kiel) - Schneiderhofer, Petra (Vestfold and Telemark County Council) - Verhegge, Jeroen (Department of Archaeology, Ghent University; Department of Environment, Ghent University; GATE Archaeology)

**Abstract format:** Oral

Mapping past hunter-gatherer landscapes remains a long standing challenge in archaeological survey. Over the past decades, many prospection techniques have been developed that try to account for the scale and subtlety of the elusive targets characterising these lifeways. The range of regions in which integrated prospection approaches are applied, is expanding continually. While sub-aqueous, wetland and sedimentation areas pose specific technical complexities, the search for Palaeolithic and Mesolithic occupation in dryland environments, mountainous regions or even submerged areas is pushed by academic framework and the mitigation responses to land-use and development.

While some techniques, including traditional approaches such as test pitting, are well established, advancement on adaptive sampling strategies or continual scrutiny of deployed field approaches remains limited. The same goes for other methods that have a more regional 'acceptance', such as systematic auger surveying in Belgium and the Netherlands. These provide opportunities beyond local applications, and often hold an untapped potential for developing comprehensive survey approaches that increase the scientific revenue as well as the economic efficacy of field practice. Lastly, the introduction of novel investigative methods such as remote sensing or geophysical prospection has heralded a 'prospection positivism' in some schools. While such approaches can resolve (sub)surface variation at an unrepresented spatial scale and sensitivity, the increased effort towards automated interpretation schemes does raise concern for omitting hunter-gatherers from the 'non-invasive' archaeological record.

In this presentation, we provide an overview of traditional and non-traditional approaches to prospecting hunter-gatherer environments and the material remains that enable us to study them. We will start by delineating the targets that define these from an archaeological and environmental standpoint, and evaluate how common approaches are optimal – or inefficient – in resolving these. Lastly, we will propose future pathways to a more sustainable evaluation and reliable investigation of these elusive lifeways.

**DUVENSEE PALAEO-DATA IN NEW LIGHT: RE-EVALUATION OF ON- AND NEAR-SITE SEDIMENT SEQUENCES FROM THE MESOLITHIC**

**Abstract author(s):** Wieckowska-Lüth, Magdalena - Dörfler, Walter (Institute of Pre- Protohistoric Archaeology, University of Kiel)

**Abstract format:** Poster

The intensive archaeological research in the ancient lake Duvensee was accompanied several times by the palynological studies. However, these were mainly restricted to archaeological purposes, that is, dating of hunter-gatherer sites and clarifying questions about the stratigraphy, rather than being regarded as essential for understanding of the temporal evolution of the palaeolake area. This poster presents a re-evaluation of the hitherto results of the palynological research carried out in the Duvensee area, referring to several both published and unpublished on- and near-site early Holocene sediment sequences.

Owing to this holistic view of the paleo-data it was possible to identify common developments. While more or less continuous use of the Duvensee area could be detected in most of the pollen records since the beginning of the Boreal, hydrological changes at the transition from the early to the late Boreal seem to have had an impact on the Mesolithic land-use. During this phase, evidence of open-land indicators decreases, often correlating with a hazel decline. The poster takes up the discussion of whether hazel may have been encouraged either by human activities, or that climatic changes may have temporarily slowed down its spread.

**MODELLING COMPLEXITY: PAST INTERACTIONS BETWEEN PEOPLE, CLIMATE AND ENVIRONMENT [PAM]**

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Burke, Ariane (Universite de Montreal; Oeschger Centre for Climate Change Research) - Riede, Felix (Aarhus University)

**Format:** Regular session

Conveying a sense of place and measuring the importance of environmental services for people in the past are difficult tasks. Understanding the relationship between prehistoric human populations and the world around them requires the ability to reconstruct key aspects of the palaeoenvironment – from large-scale drivers of environmental conditions, such as climate, to more regional variables such as vegetation cover and faunal communities. Computational archaeology is leading the way in the study of past human-environment interactions across spatial and chronological scales. With the increased availability of high-resolution climate models, palaeoecological proxies and the mature use of GIS-aided ecological modelling, archaeologists working in interdisciplinary settings are well-positioned to explore the intersection of human systems and environmental affordances and constraints. These methodological advancements provide a better understanding of the role humans played in past ecosystems – both in terms of their impact upon the environment and, in return, the impact of environmental conditions on human systems. They may also allow us to infer past ecological knowledge and land-use patterns that are historically contingent, rather than environmentally determined. This session seeks contributions that combine reconstructions of past environments and archaeological data with a view to exploring their complex interactions at different scales and invites scholars from varying disciplines and backgrounds to present, compare and contrast different modelling approaches.

**ABSTRACTS:**

**CLIMATE NICHE MODELLING REVEALS THE FATE OF PIONEERING LATE PLEISTOCENE POPULATIONS IN NORTHERN EUROPE**

**Abstract author(s):** Pedersen, Jesper (Department of Archaeology and Heritage Studies, Aarhus University Moesgård; Center for Biodiversity Dynamics in a Changing World - BIOCHANGE, Department of Biology, Aarhus University) - Assmann, Jakob - Normand, Signe (Department of Biology - Ecoinformatics and Biodiversity, Aarhus University; Center for Biodiversity Dynamics in a Changing World - BIOCHANGE, Department of Biology, Aarhus University) - Karger, Dirk (Swiss Federal Institute for Forest, Snow and Landscape Research WSL; Center for Biodiversity Dynamics in a Changing World - BIOCHANGE, Department of Biology, Aarhus University) - Riede, Felix (Department of Archaeology and Heritage Studies, Aarhus University Moesgård; Center for Biodiversity Dynamics in a Changing World - BIOCHANGE, Department of Biology, Aarhus University)

**Abstract format:** Oral

Following deglaciation during the final stages of the Pleistocene, vast landscapes became increasingly accessible for human dispersal. With no historical analogues, it remains uncertain how people were adapting to these unknown and often unstable environments and whether dispersals were sustained or characterised by local retreat or extinction events. We address these uncertainties by using climate niche modelling to investigate the relationship between climate and the archaeological record of such a dispersal event: the Late Upper Palaeolithic Hamburgian settlement of northern Europe. Our models consider temperature and precipitation from paleo climate models with high temporal (100 yrs) and spatial resolution (c. 1km). They suggest that rising temperatures instead of precipitation changes drove dispersal events by allowing carriers of the Hamburgian tradition to occupy a specific, northward shifting climate space. Similarly, our models suggest a subsequent constriction and fragmentation of this climate space caused by declining temperatures. This climatic downturn and shifting climate space coincides with the disappearance of the Hamburgian tradition from the archaeological record. We argue that this sudden climatic change pushed the social and demographic costs of northward dispersal to become unsustainable, leading to a depopulation of the region.

2

OF HUNTING, GATHERING AND FISHING: EXPLORING SOCIO-ECOLOGICAL DYNAMICS USING AGENT-BASED SIMULATIONS

**Abstract author(s):** Günther, Gerrit (Department of Geography, Physical Geography, Christian-Albrechts-Universität zu Kiel; CRC 1266: Scales of transformation: Human-environmental interaction in prehistoric and archaic societies - SFB 1266, Christian-Albrechts-Universität zu Kiel) - Groß, Daniel (Centre for Baltic and Scandinavian Archaeology - ZBSA – Schleswig-Holstein State Museums Foundation Schloss Gottorf; CRC 1266: Scales of transformation: Human-environmental interaction in prehistoric and archaic societies - SFB 1266, Christian-Albrechts-Universität zu Kiel) - Knitter, Daniel (Department of Geography, Physical Geography, University of Kiel; CRC 1266: Scales of transformation: Human-environmental interaction in prehistoric and archaic societies - SFB 1266, Christian-Albrechts-Universität zu Kiel) - Strohm, Steffen (Department of Computer Science, Christian-Albrechts-Universität zu Kiel; CRC 1266: Scales of transformation: Human-environmental interaction in prehistoric and archaic societies - SFB 1266, Christian-Albrechts-Universität zu Kiel) - Wieckowska-Lüth, Magdalena (Institute of Prehistoric and Protohistoric Archaeology, Archaeobotanical and Palynological Laboratory, Christian-Albrechts-Universität zu Kiel; CRC 1266: Scales of transformation: Human-environmental interaction in prehistoric and archaic societies - SFB 1266)

**Abstract format:** Oral

Land use practices and spatial organization are integral to understand past human-environment interactions. Especially in hunter-gatherer-societies with their elusive material culture, it becomes important to find ways for interpreting the archaeological data. Agent-based modelling is a method, which provides a bottom-up approach for studying complex systems. In this presentation, we focus on the Mesolithic on the Northern European Plain and provide an abstract, modular simulation tool that allows investigating various aspects and possibilities of socio-ecological dynamics and environmental perception of past societies. In order to test hypotheses regarding different land use patterns and strategies, socio-ecological concepts are combined with advanced computational modelling techniques. Transferring these concepts into a simulation using the Julia programming language we provide first results that showcase agent-based models as useful tools for discussing hypotheses and bridging the gap between archaeological data and socio-ecological dynamics. Our model contributes to understanding hunter-gatherer-societies by an integrative perspective of theoretical approaches and empirical data.

3

CHALLENGES IN USING COMPUTATIONAL ARCHAEOLOGY WITH LIMITED DATA: A CASE STUDY FROM FINAL PALAEOLITHIC SCHLESWIG-HOLSTEIN

**Abstract author(s):** Grimm, Sonja - Eriksen, Berit (ZBSA - Centre for Baltic and Scandinavian Archaeology; CRC 1266) - Günther, Gerrit - Hamer, Wolfgang - Knitter, Daniel (CAU Kiel; CRC 1266) - Krüger, Sascha (National Museum of Denmark) - Weber, Mara-Julia (ZBSA - Centre for Baltic and Scandinavian Archaeology; CRC 1266) - Wild, Markus (CAU Kiel; Cluster of Excellence “ROOTS”)

**Abstract format:** Oral

Using computational modelling is a promising field in combining palaeoenvironmental and archaeological research. However, a model always represents a simplification and analysing complex connections such as human-environmental interactions requires a solid conceptual fundament and the respective data base. Source criticism is essential to differentiate past patterns from analytical limits. For instance, the idea of developing an inductive predictive model for finding sites of the different Final Palaeolithic technocomplexes in Schleswig-Holstein could not be developed straightforwardly due to the small number of sites in regard to the size of the region and the timespan. The palaeoenvironmental archives are also limited and reflect shifting ecological zones across Schleswig-Holstein during the Lateglacial. Furthermore, the landscape has changed significantly since the deposition of Final Palaeolithic material with the accumulation of coversands and tidal plains, the development of peat bogs from open water bodies, wind ablation, permafrost development and melting. Hence, modern DEMs do not reflect past landscapes and cannot be adapted by simple equations. We are lacking detailed information about the development in large parts of the landscape what makes geostatistical analyses difficult to impossible.

Yet, advanced computational methods can help evaluating our hypotheses if we can transform these conjectures into spatially explicit data and test them against the available archaeological and palaeoenvironmental sites and material. For instance, the incorporation of fuzzy logic allows us to map our limited knowledge as linguistic variables. The benefit of this rule-based approach is that it reflects our hypotheses and answers questions concerning, for instance, key palaeoenvironmental aspects for Final Palaeolithic humans and traditional choices of placing a camp.

4

THE LAST OF THEM. INVESTIGATING THE PALAEOGEOGRAPHY OF THE LAST NEANDERTHALS IN EUROPE (MARINE ISOTOPIC STAGE 3; 60-27 KY BP)

**Abstract author(s):** Albouy, Benjamin - Burke, Ariane - Riel-Salvatore, Julien (Université de Montréal)

**Abstract format:** Oral

Neanderthals (*Homo neanderthalensis*) are the best-documented extinct human species to this day. They are generally associated with the material culture known as the Mousterian. They occupied a large part of Eurasia, starting around 350 ky Before Present (BP) until their disappearance around 40 ky BP. In this context, Marine Isotopic Stage 3 (MIS 3), lasting 60-27 ky BP, constitutes a key period to consider their adaptability and to clarify the reasons behind their extinction. Further, this period was marked by both abrupt climatic change, and the arrival of Anatomically Modern Humans from the East. Hence, it is crucial to investigate the precise impact of each of these elements on Neanderthal behavior.

While much research has focused on the specific conditions of their extinction, we present here a new doctoral research project that aims to assess more precisely the influence of abrupt climatic change on the Neanderthal settlement of Europe during MIS 3. This project, taking place within the Hominin Dispersal Research Group (HDRG), involves a multidisciplinary approach combining a large corpus of archaeological and paleoclimatic data used to develop species and ecological distribution models. We detail here the first step of this project, focusing specifically on the collected archaeological data. The resulting database, built from a comprehensive literature review, is the foundation of our work and will also constitute an open-access resource for further research and collaborative projects. We conclude with an in-depth discussion of our methodology for integrating these data with the paleoclimatic data and how they will be used to build habitat suitability models of unprecedented temporal and spatial resolution.

5

TOWARDS COMPLEX MODELLING: HUMAN-ENVIRONMENT INTERACTION IN EUROPE DURING GLACIAL-INTERGLACIAL CYCLES

**Abstract author(s):** Schmidt, Isabell - Limberg, Heiko - Klein, Konstantin - Wegener, Christian (University of Cologne) - Weniger, Gerd-Christian (Neanderthal Museum) - Hense, Andreas (University of Bonn) - Rostami, Masoud - Shao, Yaping (University of Cologne)

**Abstract format:** Oral

Climatic change during glacial-interglacial cycles of the Late Pleistocene have raised intense discussions about its effects on humans’ resilience, their survival, socio-cultural and economic adaptations, and dispersal processes. In this study, we use the human-existence potential model to investigate how climate change influenced the distribution and dispersal of humans, taking the expansion of Anatomically Modern Humans into Europe a case study.

A global climate model is used to simulate extreme climate conditions of stadial and interstadial periods. These simulations underlie the human-existence potential model, which combines climate and archaeological data and provides an estimate on the human existence probability at each given location. We find that climate change profoundly influenced human dispersal during the Aurignacian. Several hot-spot areas located in the climate shadows of large topographic features may have played important roles during cold conditions. However, we also observe interesting mismatches which could indicate evidence of specific human adaptation during this time frame. In general, the contrast between the high temporal resolution of the climatic record and low resolution available for the archaeological record requires careful adjustment of the research questions addressed at this scale. However, high potential is identified for its application to long temporal time-series and the integration of additional environmental and socio-cultural factors.

6

LANDFORMS AND HABITATS: A DIACHRONIC PERSPECTIVE ON UPPER PALAEOLITHIC LAND USE IN EUROPE

**Abstract author(s):** Schoenenberg, Jonathan - Sauer, Florian (University of Cologne)

**Abstract format:** Oral

The geomorphology of landscapes influences a variety of different abiotic factors such as precipitation, evapotranspiration or soil formation. Hydrological conditions in the landscape are regulated and directed by valleys and peaks while insolation changes with elevation and exposition of different landforms. Local topography has an indirect effect on biotic factors by defining the framework for plant societies and the accompanying fauna. Therefore, topography and landforms are proxies for the patterning of biocoenoses and its resulting bioeconomic potential. We use the diversity of different landforms in modelled catchments of prehistoric sites to quantify this bioeconomic potential.

In this presentation we show the methodological framework and initial results of the analysis of bioeconomic resource potential for the Upper Palaeolithic (c. 42–10 ka BP) on a continental scale.

First results of the project allow to quantify the difference between generally available landscapes and settled regions. The diachronic comparison throughout different technocomplexes reveals further distinction in the interaction between humans and their surrounding environment. We also identify regional trends by synchronous comparison of different chronological phases and regional units. At this point of research, we can document a strong correlation between the diversity of catchments in different chronological phases and global climatic trends. During warmer periods of the last glaciation a preference for low variance in landform distribution resulting in a lower bioeconomic potential can be observed. In turn, hunter gatherers favoured higher diversity within catchments during colder phases such as the Last Glacial Maximum.

Discussing our modelling results, we will illustrate potential implications on the Upper Palaeolithic land use in Europe and compare these against common mobility theories.

7

THE IMPACT OF MAGDALENIAN HUNTER-GATHERERS ON THEIR ENVIRONMENT

**Abstract author(s):** Gravel-Miguel, Claudine (Arizona State University)

**Abstract format:** Oral

Anthropological and ethnographic research has shown the influence of climate and resource distribution on hunter-gatherer lifestyle. As a result, an increasing number of archaeologists have attempted to reconstruct past environments to understand behavior in its context. However, to this day, only a few have considered the possibility that hunter-gatherers themselves impacted the environment and resources on which they relied. This research aims to reconstruct Southwest European Magdalenian environment and

8 evaluate the potential impact that Magdalenian hunter-gatherers had on that environment. It uses the biomization method, focusing on the distribution of 77 plant taxa aggregated into 13 plant functional types (PFT), which are then grouped into biomes. The modern distributions of the PFT are assessed through crowd-sourced data, and a model of their climate requirements is built using MaxEnt. Those requirements are then applied to Magdalenian climate to reconstruct the PFT’s probable prehistoric distributions. Magdalenian climate maps are reconstructed using WorldClim and data from the Trace-21ka global climate model. In the scenario without human impact, the PFT distributions are combined to form biomes. In the scenario with human impacts, a MaxEnt model is built using archaeological sites to predict the distribution of Magdalenian hunter-gatherers, which affects the threshold of PFT’s presence prior to being combined into biomes. The reconstructed biomes of both scenarios are then compared to the archaeological pollen record to evaluate which scenario (with or without human impact) fits the empirical data best.

8 **RETHINKING THE IMPORTANCE OF EUROPEAN RABBIT (ORYCTOLAGUS CUNICULUS) IN THE HUMAN DIET DURING THE UPPER PALAEOLITHIC IN IBERIA**

**Abstract author(s):** Seuru, Samuel (Département d’Anthropologie, Université de Montréal) - Perez, Liliana (Département de Géographie, Université de Montréal) - Burke, Ariane (Département d’Anthropologie, Université de Montréal)

**Abstract format:** Oral

Understanding interactions between prehistoric human populations and faunal communities requires a combination of theoretical models and computer-based simulations to reconstruct key aspects of cynegetic behaviors such as small game hunting. Today there exists no general consensus as to the causes of the introduction of the European rabbit (*Oryctolagus cuniculus*) into the diet of Palaeolithic hunter-gatherers in Iberia. One hypothesis is that resource stress, caused by an imbalance between human and ungulate populations in Iberia during the Last Glacial Maximum, drove people to expand their diet breadth. Because this hypothesis is grounded in Optimal Foraging Theory, we use this conceptual framework to build an agent-based model (ABM). The goal of the ABM is to evaluate the impact of the resource stress hypothesis on the zooarchaeological record and better understand its implications. The results bring a new perspective to the intense debate surrounding the interpretation of the large number of European rabbit remains in Iberian sites during Upper Palaeolithic.

9 **WHERE THE GRASS IS GREENER: ESTIMATED VEGETATION PERIODS AND THEIR EXPLANATORY POTENTIAL FOR SITE DISTRIBUTION IN THE EAST EUROPEAN PLAIN**

**Abstract author(s):** Tharandt, Louise - Linsel, Florian - Maier, Andreas (Institute of Prehistoric Archaeology, University of Cologne) - Ludwig, Patrick (Karlsruhe Institute of Technology, Institute of Meteorology and Climate Research, Department Troposphere Research - IMK-TRO)

**Abstract format:** Oral

Migrating animals often show a behavior that is termed “surfing the green wave”, i.e. they move to patches of land where plants just started to sprout. Timing and conduct of such movements likely have been of interest for prehistoric hunter-gatherers. Particularly in areas with a comparatively homogeneous topography, such as the East European Plain, these movements might have been a strong factor influencing the distribution of site and consequently the intensity of contact and interaction between different groups. In this paper, we present estimates on the timing of the vegetation period in the East European Plain between 40 ka (GI-9) and 27 ka (GS-3). We explore the differences and shifts in the start and end of the vegetation periods with regard to Stadial and Interstadial conditions. Evaluating the explanatory potential of the emerging pattern, we compare the results with the site distribution during the different periods as well as the formation of larger taxonomic units. We conclude that differences in the estimated timing of the vegetation period in different parts of the East European Plain are helpful to understand the large-scale structure of the archaeological record between the Vistula River and the Ural Mountains.

10 **ABOUT PEOPLE AND LOESS. MODELLING DUST EMISSION AND IMPLICATIONS FOR THE PEOPLING OF NORTH-WESTERN FRANCE DURING THE LAST GLACIAL MAXIMUM**

**Abstract author(s):** Boisard, Solène (Hominin Dispersals Research Group, Department of Anthropology, University of Montreal) - King, James - Chaput, Amélie - Gauvin-Bourdon, Philippe (Wind Erosion Laboratory, Department of Geography, University of Montreal) - Burke, Ariane (Hominin Dispersals Research Group, Department of Anthropology, University of Montreal)

**Abstract format:** Oral

Human settlement dynamics are influenced by ecological and social factors. In North-Western France, the scarcity of archaeological sites dating to the Last Glacial Maximum (LGM) is commonly assigned to periglacial conditions characterized by important loess accumulations. The emission processes, their sources, and the transport of loess as well as its extent in this region are not well defined and explained. It is commonly assumed that loess material comes from a major and distant source: the English Channel/ North-Sea, a large exposed periglacial area during the lowering of sea level. However, research on passive (geological and geoarchaeological regional map) and active (global paleoclimatic models with dust production models) geomorphology are rarely confronted, opening issues about the ancient ecosystems and their habitat suitability for ancient populations.

This preliminary study combines two approaches and multiple sets of data. To study passive geomorphology, spatial analysis of loess deposits thickness available in northern France were set against potential sources of emissions from the English Channel. This approach emphasizes on geomorphology patterns (topography and hydrography). The active methods consist of modelling the

regional LGM climate in Northern France, via existing global paleoclimate models, driving a Lagrangian trajectory model (FLEXPART) to study various potential dust sources. Modelling results are correlated and contrasted against loess analysis maps, to verify the accuracy of the potential dust sources. Unique or multiple origin dust influence regional soil type, and by extent vegetation, a situation that could lead to more contrasted ecological patchwork and influence movements dynamics of faunas and humans.

11 **REFLOATING THE AEGEAN LOST DRYLAND: AN AFFORDANCE-BASED GIS APPROACH TO EXPLORE THE INTERACTION BETWEEN HOMININS AND THE PALAEOLANDSCAPE**

**Abstract author(s):** Tsakanikou, Peny (Palaeolithic Lesbos Research Project, University of Crete; Centre for the Archaeology of Human Origins, University of Southampton)

**Abstract format:** Oral

Recent palaeogeographical reconstructions for the past 400ka provide solid evidence for the occurrence of subaerially exposed landmasses over the northern and central Aegean during the glacial low stands of the Middle Pleistocene (from at least MIS 12). Similar conditions could be extended as far back as the Early Pleistocene or even the Late Pliocene, based on current knowledge of the tectonic evolution of the Aegean.

These former terrestrial environments, which now lie underwater, connected Western Asia to Europe via the Greek mainland, offering opportunities for settlement and dispersal to hominin groups. The Aegean dryland would constitute the extension of the Balkan refugial zone over the NE Mediterranean, hosting variability-rich resources and protected niches during extreme climatic phases. In spatial terms, a whole new arena for the LP research is now revealed at the crossroads between Africa, Europe, and Asia.

Understanding the interaction between hominins and this newly revealed, former terrestrial landscape in the deep past has proven to be quite challenging due to the dynamic nature of the Aegean region. Despite these challenges, through GIS-based suitability analysis and predictive modelling, we can begin to formulate a better understanding on the nature of this interaction.

This paper will present an interdisciplinary approach, integrating archaeology, palaeoenvironments and palaeogeography within an affordance-based GIS framework, to explore further the affording palaeolandscape and the hominin response to it. Predictive modelling based on suitability and landscape legibility led to the identification of potential trans-Aegean corridors of opportunity for dispersal and occupation zones during the Early and Middle Pleistocene.

This work is hoped to instigate future LP research and renew interest in the Aegean by fostering a new cycle of discussion on the biogeographical importance of the wider NE Mediterranean during the early settlement(s) of the European continent.

12 **GIS-AIDED MODELLING OF NEOLITHIC SOIL EXPLOITATION IN THE SOUTH OF EASTERN EUROPE**

**Abstract author(s):** Kiosak, Dmytro (Ca’ Foscari University of Venice) - Radchenko, Simon (Universita degli Studi di Torino)

**Abstract format:** Oral

Neolithic farmers had certain patterns of soil exploitation, which were well established in Central Europe. There are particular sedimentary conditions at many Neolithic sites in the south of Eastern Europe (modern-day Ukraine, Moldova and Romania). The remains of Neolithic houses are covered by thick (sometimes over 1 meter) layer of later Holocene deposits. On the one hand this situation makes any large scale excavation of these sites a difficult enterprise, on the other hand it opens the possibility to study the soil sequence looking for trends of change during Holocene.

In this work we study the geographical correspondence between sites of several Neolithic cultures and the modern soil distribution. In order to carry out the comparison we compiled the database, which was designed in PostgreSQL, and digitalized (in QGIS) a dataset of soil maps provided for agricultural purposes. The results indicate a variable patterns of soil exploitation throughout Neolithic. Furthermore, several case-studies (Linear Pottery Culture site Kamyane-Zavallia, Trypillia sites Sabatynivka 1 and Kamyane-Zavallia I) enable us to verify the correspondence of modern soil cover to the soil cover of Neolithic in different geomorphologic contexts. This possibility forms a basis for modelling of the soil distribution in Neolithic in a given microregion. The latter is carried out in a shape of GIS-project.

13 **FROM CELLS TO BEHAVIOURS. MODELLING PASTURES AND CROPS IN A RASTER GIS SYSTEM STARTING FROM LANDSCAPE (PALEO-)DATA**

**Abstract author(s):** Sotgia, Agostino (Sapienza - University of Rome; RUG - University of Groningen)

**Abstract format:** Oral

The exploitation of landscape resources has always been the main type of relationship between human communities and the environment where they live. Agriculture and pastoralism represent the first level of rational exploitation of the landscape by man and above all for the prehistoric communities they are the most evident sign of their action.

For this reason, a GIS cell-raster model has been developed that is capable of the identification of the area most suitable for the agro-pastoral exploitation.

Combining information from landscape survey, excavations and palynological and archeozoological analyses, I will propose a land use model, based on these primary data, informed by studies on pre-modern agricultural techniques (as the Latin agronomists Columella or Pliny), as well as on contemporary agricultural requirements (FAO - land evaluation).

Using the Analytic Hierarchy Process method, the system carries out an integrate multi-criteria analysis of various variables such as: soil types, slope and sun exposure of land, area elevation or the distance from water resources, as well as effect of the phenomenon of erosion on the lands or the wetness present in the area.

Once the landscape’s areas most suitable for agro-pastoral exploitation have been identified, it will be possible to analyse their relationship with archaeological sites using all the typical tools of the archaeological discipline, whether they are the most typical of space archaeology or the new, more phenomenological approaches.

The paper presented intends to illustrate in detail the structure and functioning of the GIS model developed, as well the different possible applications in archaeological contexts.

14

POPULATION DENSITY DRIVES FARMER SETTLEMENT AND ABANDONMENT OF MARGINAL ENVIRONMENTS

**Abstract author(s):** Yaworsky, Peter (Department of Archaeology and Heritage Studies, Aarhus University; University of Utah Archaeological Center; Department of Anthropology, University of Utah) - Coddington, Brian (University of Utah Archaeological Center; Department of Anthropology, University of Utah; Global Change and Sustainability Center, University of Utah)

**Abstract format:** Oral

While archaeological research throughout the world documents the spread of farming communities following regional domestication events, explaining the variation in their timing and persistence remains contentious. Leveraging insights from behavioural and population ecology, we examine the factors that drive farming populations to occupy and abandon marginal environments. We assess the rise and collapse of farming communities in the West Tavaputs Plateau in the southwestern USA. Early farmers in the region lived at the northern extent of where agriculture was possible. With its high plateaus, deep canyons, and limited perennial water sources, the arid environment resulted in both short growing seasons and a paucity of water. We use the ideal free distribution model to investigate the occupation and abandonment of habitats across the West Tavaputs Plateau. We find that neither occupation nor abandonment is driven by variation in precipitation, but by other factors that affect population size. This finding has two significant implications. First, it supports the idea that farmers on the West Tavaputs Plateau were not dry farming, but primarily reliant on perennial water sources for crop irrigation. Second, settlement and abandonment events appear to mirror one another, with lower-ranked habitats being occupied last and abandoned first. These results have important implications for understanding the resilience of farming in marginal environments around the world.

298

THE LONG FOURTH CENTURY BC: TRACING THE TRANSFORMATION OF SOUTHERN ITALY IN ITS MEDITERRANEAN CONTEXT

**Theme:** 4. Globalisation and archaeology

**Organisers:** Heitz, Christian - Hoernes, Matthias (University of Innsbruck) - Henning, Agnes (Humboldt University, Berlin) - Robinson, Ted (University of Sydney)

**Format:** Regular session

Thirty years ago, Nicholas Purcell recognised a ‘long’ fourth century BC, between the late fifth century and the end of the Pyrrhic War, as the “heroic age” of Southern Italy. This period saw significant dynamics in the construction of urban and rural landscapes as settlements transformed into cities, many of them fortified. Hinterlands were scattered with farmsteads, new sanctuaries appeared and new forms of local identity emerged. Tombs increased exponentially in number and lavishness; larger tomb types arose, funerary cult intensified and increased social stratification is strongly implied. Over this period, craftsmanship underwent specialisation and the production of red-figured and glazed pottery grew into an industry that flooded the inland with commodities and led to the establishment of workshops there. Nevertheless, this period has primarily been regarded as a phase of constant turmoil and crisis, into which the so-called ‘condottieri’ are thought to have thrown the South on the eve of the Roman conquest. Predominantly based on the literary evidence, such narratives fall short of this highly dynamic period, in which longer developments tied in with accelerated change and Mediterranean connectivity and transculturality thrived more than ever before.

Purcell had already voiced the hope that archaeology could construe a new narrative by going “beyond the simple evolutionist perspective of analysing hundreds of local experiences in geographical order” and instead making sense of them within a broader historical process. After three more decades of archaeological work, it is now time to sketch a narrative of the ‘mezzogiorno’ and to trace transformative dynamics on the basis of the archaeological evidence. We invite papers presenting in-depth studies of manifestations of regional dynamics, surveys with a sensitivity for local particularities, or comparative perspectives from neighbouring regions in the Mediterranean, which focus on, but are not limited to, the topics touched on above.

ABSTRACTS:

1

TRANSFORMATIVE DYNAMICS IN THE 4TH CENTURY BC MESSAPIA

**Abstract author(s):** Meo, Francesco (University of Salento)

**Abstract format:** Oral

Messapia corresponds to the southeastern edge of Italy. During the last few decades, extensive archaeological research has been conducted into Messapian settlements. This paper will focus on transformation of the settlements and territory in this area, through social dynamics and material culture.

Despite the fact that most of the evident transformations of this population (the introduction of writing, the construction of a road system, the change of domestic architecture and of funerary practices) occur during the 6th cent. BC, new researches are demonstrating several consistent, even if less evident, changes in some settlements during the second half of the 4th cent. BC.

As in the case of the Archaic period, these transformations are rather internal to societies, led by the local aristocracies.

As for the whole southern Italy, also Messapian settlements build imposing surrounding walls in the 4th cent. BC, whose dimension demonstrate the importance of the centre in a sort of civic competition. In the case of Muro Leccese, they totally redefine the town as they are built destroying some funerary nuclei and outer clusters of dwellings and occupying about 30 hectares of a new area.

Together with walls, changes consist in the construction of larger dwellings (Vaste), sometimes with a mosaic floor (Oria) and of monumental tombs (the ‘Ipogeo Palmieri’ at Lecce, the ‘Ipogeo delle Cariatidi’ at Vaste and a new hypogeum found at Muro Leccese) whose decoration reflect the cultural *koinè* with Macedonia and Epirus, through Taranto.

On the other hand, in daily life Messapian communities became markedly less open to external cultural experiences, reflecting a pronounced conservatism among the local ruling classes. The building techniques replicated those of the Archaic period, while the ceramics used for daily purposes included far fewer imported items, limited almost exclusively to amphorae of wine.

2

VENAFRO PROJECT: THE RISE OF HILLTOP FORTIFICATIONS IN SAMNIUM IN THE 4TH CENTURY BC

**Abstract author(s):** Hoer, Alexander (Universität Zürich)

**Abstract format:** Oral

The tribes referred to as “Samnites” by Roman sources were particularly noted for their ferocity. Samnites allegedly posed a threat to Roman hegemony and were subsequently fought in several wars beginning in the 4th century BC.

The image of Samnites conveyed in literary sources has recently been challenged by archaeological research, which has focused especially on sanctuaries and settlement patterns. An important feature, has however, received little attention so far: the rise of hilltop settlements and military outposts surrounded by massive megalithic walls.

The aim of this paper is to provide a reassessment of these hilltop fortifications through fieldwork and new theoretical approaches. Three extensive field survey campaigns of the region around Venafro, carried out in 2017 and 2018, serve to document several hill-forts and their surrounding features in more detail. Therefore, the paper discusses the new results carried out in these field campaigns. They provide a new perspective on the broader territorial and historical context and the nature of hilltop fortifications.

THE SPATIAL AND SOCIAL TRANSFORMATION OF THE SETTLEMENTS BY FORTIFICATION WALLS IN THE MOUNTAINOUS INLAND OF SOUTH ITALY

**Abstract author(s):** Henning, Agnes (Winckelmann-Institut, Humboldt-Universität zu Berlin)

**Abstract format:** Oral

Due to the geomorphology, the mountainous inland of South Italy was characterized by hill top settlements since the late Bronze Age. Although we have only little evidence for the organisation of the settlements in the first half of the 1st millennium BC which were probably structured as single clusters, a radical transformation and a completely new layout of the settlements is to be observed since the 4th century BC. Older buildings and even necropolises were given up and overbuilt. The most significant change was the construction of fortification walls. The fortifications surrounded and protected the settlements from now on, but they also bounded and defined the settlements towards the external space and made them visible from far away. These enormous building projects - which have been executed not only in the South Italian inland but also in the whole Mediterranean and which coincided with the development of new war techniques - were a novelty and an economical, logistical and technical challenge. New technologies were applied which in this extend have never been used before. This demonstrates that the fortifications had a high value for the single settlements which cannot only be reduced on the defensive function of the walls. Furthermore, they have to be seen in a wider context of the South Italian communities in the 4th and 3rd century BC.

In my paper I will present these transformations and ask their dynamics, which are related to the graduate growth of the Roman influence towards the South.

4	<p><b>VISUAL CONNECTIVITY AND CONTROL: LUCANIAN FORTIFIED CENTRES</b></p> <p><b>Abstract author(s):</b> Myers, Brett (Australian Archaeological Institute at Athens; University of Sydney)</p> <p><b>Abstract format:</b> Oral</p> <p>This paper will investigate models of fortification systems used during the 4th century BC in ancient Lucania. Over seventy fortified centres are known in Lucania from this period and we will examine how the environment of the uplands of Basilicata could have helped shape Lucanian settlement patterns and how some of these settlement patterns were seemingly tempered by proximity to neighbouring Greek colonies on the Ionian and Tyrrhenian coastlines. Combining GIS and network analysis a number of questions will be examined: Were the positions of Lucanian fortified centres influenced by an ability to remain in visual contact with each other, at least within a number of discreet groups? Were their locations influenced by the amount of visual control their elevated positions afforded over communication and trade routes? Did proximity to Greek coastal colonies modify upland settlement patterns?</p> <p>The results of this survey on the fortified centres can help construct an understanding of the regions sites and the people who inhabited them.</p>
5	<p><b>CONTINUITY AND TRANSFORMATION: SOME EXAMPLES OF STOAI AND THESAUROI ORGANIZING THE PUBLIC AND RELIGIOUS SPACE</b></p> <p><b>Abstract author(s):</b> Pollini, Airton (Université de Haute-Alsace) - Montel, Sophie (Université de Franche-Comté, Besançon)</p> <p><b>Abstract format:</b> Oral</p> <p>Recent studies on Greek architecture and topography have increasingly examined the complexity of the determination of specific functions attributed to some monuments. Some monumental structures, mainly stoai and thesauroi, are found in communal spaces (public and religious) such as agorai and sanctuaries scattered almost everywhere in the Greek world, including South Italy. Their architecture was also adopted by several Italic communities. The functions of these monuments are multiple, or rather undetermined, with a very wide range of purposes depending mainly on their contexts and local history: functions may then be linked to politics, economic activities, religious acts or even philosophical debate; stoai and thesauroi may also serve as memorial places for the community and as a privileged space for the disposition of offerings, including weapons and statues, honorific and sacred.</p> <p>After the publication of a collective work on the organization of space in fourth century BCE (Montel-Pollini ed., <i>La question de l'espace au IV<sup>e</sup> siècle avant J.-C. dans les mondes grec et étrusco-italique</i>, 2018), we propose to pursue our analysis on the layout of some communal spaces (agorai and sanctuaries) taking into consideration the possibility that those vaguely defined structures (stoai and thesauroi) may also be essential in the organization and development of such spaces, during the fourth century BCE, shortly before an intensive building activity in the third century. We propose a synthetic analysis from some meaningful case studies (Metaponto, Poseidonia, Heraion Sele, Locri-Parapezza, Argos, Delphi, Epidavros, Olympia, Knidos, Smyrna) comparing the realities of both parts of the Greek world, Western and Aegean cities. In order to analyze the particularity of Italiote cities, it is essential to compare them to the Aegean: it's a necessary first step before exploring the links between Greek and Italic experiences.</p>
6	<p><b>A SYNTHESIS OF THE 'LONG' FOURTH CENTURY: THE BASE FROM UGENTO</b></p> <p><b>Abstract author(s):</b> Lualdi, Carlo (University of Warwick)</p> <p><b>Abstract format:</b> Oral</p> <p>Southern Italy between the fourth century and the early third century BC was a multicultural context: many different ethnic and political identities came in contact with each other and this caused material culture to flourish. Recent archaeological findings and studies provide new information about the Italic people settled in the Salento Peninsula, the Messapians, which are rarely mentioned by ancient literary sources. Before 1933, in the fortified settlement of Ugento, one of the largest Messapian centres located in the south-west area of the Salento Peninsula, a square base decorated by reliefs on four sides was found. The decorative apparatus of the base shows fighters on foot and riders with different equipment. Most scholars have defined the monument as a unicum dated to the end of the fourth and the beginning of the third century BC showing the spreading of the Tarentine artistic language and Hellenistic models in Messapia. Additionally, the sculptural programme of the base shows iconographic schemes and details which can be related to subjects and themes belonging to depictions dated to the early fourth century BC, which are linked to the Apulian aristocratic ideology and to models belonging to Greek heroic culture. Hence, the base from Ugento can be considered as a material synthesis of a multi-layered cultural context between the late classical and the early Hellenistic period. The present study aims to provide an updated analysis of this complex monument and its decoration based on a multidisciplinary approach.</p>
7	<p><b>SOUTHERN ITALIC WARRIORS AND THE DEVELOPMENT OF THE WESTERN MEDITERRANEAN MILITARY KOINE</b></p> <p><b>Abstract author(s):</b> Lumsden, Alastair (University of St Andrews)</p> <p><b>Abstract format:</b> Oral</p> <p>This paper examines the development of the Southern Italic military system during the 'Long Fourth Century' and the profound influence it had on other contemporary military forces in the region. It will demonstrate that southern Italic warriors acted as central agents in the evolution of the western Mediterranean military koine.</p>

8	<p><b>ITALIANS, ITALIOTES, AND HERACLES IN THE “LONG” 4TH C. BCE SOUTHERN ITALY</b></p> <p><b>Abstract author(s):</b> Wright, Parrish (University of South Carolina)</p> <p><b>Abstract format:</b> Oral</p> <p>The importance of Heracles to Italic communities across southern Italy in the “long fourth century” is attested through cult sites, ubiquitous bronze statuettes, and can be inferred from his appearance on Bruttian coins in the 3rd century. Later foundation stories for the Bruttians indicate that descent from Heracles formed a central aspect of their identity.</p> <p>While Italic identities were crystalizing in Southern Italy in the 4th c. BCE, power dynamics were shifting among the Greek city states of Magna Graecia. The Italiote league, an ever-changing alliance of these Greek communities, with Croton at its head, began to modify its own imagery and mythology to include Heracles to recruit Italians as allies.</p> <p>Heracles as a “pre-foundational” figure has been seen as a justification for Greek presence in Italy, but I show that these myths could be mutually beneficial to both Greeks and the indigenous Italians, giving Italians agency in how they deployed their versions of Heracles and bringing them into a system of alliances based on shared mythology. I argue that a combination of the archaeological evidence for the worship of Heracles in Italic sites with material from Croton to shows how these networks of kinship diplomacy functioned pre-Roman southern Italy.</p>
9	<p><b>SOME NOTES ABOUT THE CONSUMPTION OF SOUTHERN ITALIAN RED-FIGURE WARE AT METAPONTO AND PISTICCI DURING THE 4TH CENTURY BC</b></p> <p><b>Abstract author(s):</b> Lecce, Lucia (Humboldt-Universität zu Berlin)</p> <p><b>Abstract format:</b> Oral</p> <p>The use of figured vases in the inland Italic contexts of Southern Italy has been interpreted as the clearest sign of acculturation, or Hellenisation from Western Greece for a long time. However, the current debate focuses on the concepts of Middle ground and Hybridity, which frames the discussion in terms of how Italics and Western Greeks influenced and contaminated each other.</p> <p>The work aims to investigate the complexity of the relationships between Western Greek and Italic populations in a small but relevant area of Southeast Italy, revisiting the debate over pictures as medium of cultural values and social communication. In particular, I will explore the dynamics related to the consumption of Southern Italian Red-figure Ware in the funerary contexts of the Western Greek colony of Metaponto and those of the Italic settlement of Pisticci, both located on the Ionian coast of Southern Italy in the modern Basilicata region, during the 4th century BC. These sites are fundamental to the understanding of the dynamics related to the consumption of figured ware, because at the beginning both communities imported figured vases from Attica. Then, Metaponto is one of the first to produce figured vases in Southern Italy, while Pisticci is the main destination of these products in the first phase of production. Moreover, a glance at the visual and material evidence of the 6th and 5th century BC will provide a broader overview beyond the separation well known in literature between imports (Attic Black and Red-figure) and local productions (Lucanian and Apulian).</p> <p>In conclusion, the paper will show whether and how the development of visual and material “languages” can shed some light into inter-community relationships in the larger context of the 4th century transformation of Southern Italy.</p>
10	<p><b>THE LONG FOURTH CENTURY BC AND THE ARCHAEOLOGY OF FOOD: “COOKING UP” SOME HISTORICAL CHANGES IN THE GREEK WORLD</b></p> <p><b>Abstract author(s):</b> Serino, Marco (Università degli Studi di Torino)</p> <p><b>Abstract format:</b> Oral</p> <p>Current research on cooking pottery – a neglected category for a long time, at least from an archaeological perspective – is disclosing a lot of potential in the attempts of reconstructing wider historical processes. For Greece, Magna Graecia and Sicily, the analysis on these vessels through their functional, morphological and technological features allow to explore numerous and different dynamics related to acceptance, resistance, hybridism as well as local workshop’s productive strategies.</p> <p>The transformation that occurred in the cooking pot’s manufacturing tradition during the “long fourth century” aims at satisfying both new culinary needs and social customs spread in this crucial period among Greece and South of Italy. Thanks to some preliminary new data provided by current excavations at Lokroi Epizephyrii, as well as information coming from other Greek and indigenous</p>

centers in Southern Italy, it is possible to observe some crucial cross-cultural dynamics through the perspective of a renewed “archaeology of food”.

11 FUNERARY PRACTICES AND CHANGES IN THE SOCIAL HIERARCHY IN LATE 4TH CENTURY CENTRAL APULIAN COMMUNITIES

**Abstract author(s):** Peruzzi, Bice (Rutgers State University of New Jersey)

**Abstract format:** Oral

This paper analyzes the evolution of burial practices in Central Apulia in the second half of the 4th century BCE; this period was characterized by the impressive increase in the number of tombs, a spike in the number of reused burials, the introduction of new shapes in the burial kit, and the growth in the size of the assemblages. Although it is possible that this reflected a demographic growth or external influences, I argue that these changes were caused by a shift in the social hierarchy of Central Apulian communities.

Evidence for the emergence of new social groups comes, for example, from the study of Apulian red figure vases, which in this period had virtually replaced both imports and local matt-painted ceramics. The vast majority of the assemblages contained pots decorated with generic and repetitive imagery; it follows that in this period there was a wider clientele with lower expectations, and potters produced vases that were generally appropriate for burial kits and could be acquired together when necessary. In contrast, the production of very large, labor-intensive, high quality vases with sophisticated iconographies illustrates the existence of a relatively smaller group of consumers who desired to visually set themselves apart from the rest of the population.

Changes were not limited to the funerary sphere. In the second half of the 4th century, Central Apulian sites witnessed also a shift in the settlement pattern, new feasting behaviors, and the establishment of local coin production. Thus, understanding the evolution of funerary practices within this broader context of transformation will help us shed new light on this highly dynamic period in the history of Southeastern Italy.

12 CRISIS OR DISINTEREST? FUNERARY “AUSTERITY” AND ELITE LEGITIMACY IN SAMNIUM, LATE FIFTH-EARLY THIRD CENTURIES BCE

**Abstract author(s):** Scopacasa, Rafael (Universidade Federal de Minas Gerais; University of Exeter)

**Abstract format:** Oral

This paper discusses potential changes in funerary display and elite legitimacy in Samnium between the late fifth and early third centuries BCE. It focuses on a sample of five funerary sites which have been more systematically excavated/published and cover a range of sizes and phases (Alfedena-Campo Consolino, San Vincenzo al Volturno, Gildone-Morgia della Chiusa, Larino-Carpineto, Termoli-Porticone). Beginning c. 400 BCE, a decline in the number of dated tombs can be identified at Alfedena and Termoli, which for centuries had probably been key arenas for local lineages to assert their power through funerary ritual. In addition, an apparent decrease in funerary display can be detected throughout the sampled sites c.400-300/250 BCE, with tombs featuring, on average, fewer grave goods and simple tomb architecture (also in comparison with neighbouring regions of central/southern Italy). Taken in conjunction with contemporaneous trends in non-funerary contexts, I consider how these developments may indicate changes in the definition of Samnite elites' place and role in society vis-a-vis subordinate groups. Ultimately, this discussion can allow us to explore how communities that were removed from major political and economic hubs responded to, and engaged with, the accelerated social, economic and political transformations that swept through the fourth-century BCE Mediterranean.

13 BURIAL CUSTOMS AND SOCIETY IN PRE-ROMAN BASILICATA: RECONSIDERING THE CAPPUCCINA TOMBS

**Abstract author(s):** Lorente Sebastián, Paloma (Université Paris1. Panthéon-Sorbonne)

**Abstract format:** Oral

Among the transformations affecting Southern Italy during the 4th c. B.C., the introduction of cappuccina tombs deserves a renewed attention, showing a greater complexity than expected. A first novelty comes from the taphonomic study of two graves from the indigenous settlement of Monte Torretta di Pietragalla: a structural analysis of cappuccina tombs reveals under their terracotta roof a variability of this funerary practice still to be studied. Moreover, the spread of this burial customs appears to be related to a more general framework of spatial reorganization in Basilicata. Despite the evidence for the Archaic period and the early Classical age, with the burials placed around and inside the housing units, during the 4th c. BC the funerary spaces moved away from the settlement.

- In this study, by re-examining the indigenous known contexts from pre-Roman Basilicata, I shall focus on the following topics:
1. The cappuccina tombs represent a new “type” of burial custom, suggesting a new attitude towards the world of the dead.
  2. They introduce complexity in the deceased treatment.
  3. Mnemata and semata at the same time, these graves indicate a new conception of funerary spaces from a symbolic and topographical point of view.

This may show a shift in the ideology of death by a community, aiming now to be buried in a common space, by marking its presence with the cappuccina “semata-tombs”.

14 NEW THOUGHTS ON THE LUCANIANS’ ETHNOGENESIS: THE CONTRIBUTION OF FUNERARY EVIDENCE

**Abstract author(s):** Battiloro, Ilaria (Mount Allison University) - Pignataro, Mariangela (Scuola di Specializzazione in Archeologia di Matera)

**Abstract format:** Oral

Debate has long raged over the historical and cultural dynamics that led to the emergence of the Lucanian ethnos. Influenced by Strabo’s account, scholarly literature has long considered the Samnite expansion into the Southern Italian peninsula as the origin of the Lucanian ethnogenesis. More recent scholarship is now reconsidering this invasionist perspective, and, rather than reducing the emergence of the Lucanians to a mere substitution of one people for another, tends to define it as internally driven. However, the concept of “Samnitization” itself has limited, if not obscured, any more nuanced interpretations of the role played by the Archaic groups of the Southern peninsula in the creation and promulgation of a uniquely Lucanian identity.

Archaeological evidence documents the existence of Lucanian burials that show chronological and cultural “outsider elements”, both in the depositional rituals and in the funerary assemblages. They therefore represent a privileged terrain to explore aspects of rupture and continuity in the pre-Lucanian to Lucanian transition. The persistence of typically Archaic funerary customs in many Lucanian sites has been variously interpreted in literature, but no contextual analysis has been made to explain this phenomenon. This paper presents the result of a re-analysis of a sample of Lucanian tombs showing anomalous aspects, which can be referred to a pre-Lucanian culture. The topographic location of the burial, the gender and social status of the deceased, depositional ritual, and grave-good assemblage are all taken into consideration. The ultimate goal of this study is to illuminate whether the inclusion of “outsider elements” in a burial was a way for members of Lucanian communities to express a “mixed” ethnic and cultural identity, or whether it was a way to retain the memory of early encounters.

15 A TOMB OF ONE’S OWN: GENERIC MODELS AND LOCAL ADAPTATIONS IN ITALIOTE AND ILLYRIAN ICONOGRAPHY (5TH-3RD CENTURY B.C.)

**Abstract author(s):** Bièvre-Perrin, Fabien (Centre Jean Bérard)

**Abstract format:** Oral

From the 5th to the 3rd century BC, so-called “tomb scenes” are very frequent in South Italian and Illyrian iconography, especially in red-figure pottery. Although apparently very generic in their composition, these scenes present subtle differences that enlighten the historian about their production and reception contexts, as well as on gender roles. In addition to the fact that the central funerary monument (naiskos, column, stele...) may vary from one region to another, artists have often singled out the protagonists, especially women, according to their ethnicity through their clothing, the objects they’re handling and probably their gestures. In this communication, we will look at the ways in which a generic Italiote scheme is recurrently used by adapting it to the commissioners according to their culture and ethnicity.

This research is based on precise quantitative analyses carried out on several hundred representations. Three devices designed within the framework of the European project Feminicon (grant number : 891118) will be used jointly: an Omeka S platform gathering documentation, a TomL language for describing the scenes and a series of R-Markdown scripts.

300 CONTACT – THE ‘OTHER’ IN EXPERIMENTAL USE-WEAR STUDIES

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Thaler, Ulrich (Römisch-Germanisches Zentralmuseum Mainz, Leibniz Research Institute for Archaeology, KB Scientific & Experimental Archaeology) - Marreiros, João (ICArEHB, Interdisciplinary Center for Archaeology and Evolution of Human Behaviour, FCHS, Universidade do Algarve; Römisch-Germanisches Zentralmuseum, Leibniz Research Institute for Archaeology, MONREPOS Research Centre and Museum, Laboratory for Traceology and Controlled Experiments) - Macdonald, Danielle (University of Tulsa)

**Format:** Regular session

The concept of alterity, an ‘other’ in contrast to which the (collective or individual) self is defined and constructed, has long been a mainstay of social archaeology. Following the material turn in the social sciences, we may also consider the agency of material objects on one another. This leads us to a fundamental, though in some respects perhaps underdiscussed, principle of use-wear studies: any object under analysis develops its defining characteristics, i.e. use-wear traces, only through contact with an ‘other’, i.e. the contact material.

While welcoming all proposals exploring the epistemology of use-wear analyses either through specific case studies or in more general terms, the session aims to put, for the first time, contact materials centre-stage in traceological discourse and especially invites contributions highlighting the role of contact material choice and treatment in experimental use-wear studies. Topics discussed might include, e.g., issues of both replicability and ethics (as well as legal ones) in the choice of natural contact materials or artificial analogues, e.g. in the study of Palaeolithic hunting or Prehistoric warfare; the diagnostic potential of comparative studies of ‘narrow ranges’ of contact materials, e.g. different plant species such as types of cereals exploited by Neolithic farmers; best practice in the choice and pre-treatment of single contact materials standing in for larger, more varied groups of materials including potential proposals for standard samples, e.g. in the study of Bronze Age axes and forest clearance.

<p>With use-wear study having taken much inspiration from the engineering and natural sciences, e.g. tribology, this session also directly pertains to a fundamental epistemological debate in the ‘hard’ sciences, i.e. the much-cited crisis of reproducibility and the (partly) resultant crisis of confidence in science: careful consideration of the traceological ‘other’ is crucial for ensuring repeatability, replicability and reproducibility in both controlled laboratory and actualistic field trials.</p>	
<p><b>ABSTRACTS:</b></p>	
<p><b>1</b></p> <p><b>USE-TRACES AND MATERIAL AFFORDANCES OF MULTIFUNCTIONAL TOOLS</b></p> <p><b>Abstract author(s):</b> Macdonald, Danielle (The University of Tulsa)</p> <p><b>Abstract format:</b> Oral</p> <p>Understanding the behaviors of past peoples is at the core of use-wear analysis studies. Building from the microscale, the identification of traces allows for broader inferences to be made about human intentionality and action. However, to understand the past, we must recreate it in the present through making and using tools ourselves. Experimental design to replicate traces can range from actualistic experiments to highly controlled movements performed by robotic devices. These differing designs each have strengths and limitations, and much can be learned through a broad approach to experimentation. However, these methods of experimentation often overlook the wider interaction networks in which the archaeological tools reside, including the nuances and affordances of the materials they connect with. In this paper, I explore the issue of multifunctionality of tools, exploring how tools exist in broader material networks and may be used for a variety of purposes and tasks.</p> <p>Starting from the microscale, this paper assesses traces of multifunctional use on experimental tools using confocal microscopy to identify the complexities of multiple contact material traces. Building outwards through the lens of Gibson’s theory of affordances, the material properties of the experimental tools are addressed in concert with the affordances of multiple contact materials to understand the dynamics of their interactions. These ideas are discussed within the framework of material agency to understand how objects are positioned within broader material/human networks. Through the exploration of tools’ interactions with multiple contact materials, we can get closer to understanding how people were positioned in past networks and how they may have interacted with the world around them.</p>	
<p><b>2</b></p> <p><b>ROBOTS IN ARCHEOLOGY</b></p> <p><b>Abstract author(s):</b> Calandra, Ivan - Schunk, Lisa (TraCEr, Laboratory for Traceology and Controlled Experiments at MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) - Bob, Konstantin (Scientific Computing and Bioinformatics, Institute of Computer Science, Johannes Gutenberg University) - Perske, Josh (Information Technology, Engineering Department, University of Applied Sciences) - Gneisinger, Walter (TraCEr, Laboratory for Traceology and Controlled Experiments at MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) - Marreiros, João (TraCEr, Laboratory for Traceology and Controlled Experiments at MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM; Institute for Prehistoric and Protohistoric Archaeology, Johannes Gutenberg University; ICArEHB, Interdisciplinary Center for Archaeology and Evolution of Human Behaviour, University of Algarve)</p> <p><b>Abstract format:</b> Oral</p> <p>Use-wear analysis relies on reference collections to identify the use of archeological tools, and these collections are created via experimentation. Traditionally, experiments are performed manually by the experimenters themselves (actualistic, pilot or first-generation experiments). While such experiments are important to identify which factors (raw material, contact material, action, duration...) influence use-wear formation, a mechanistic, cause-effect relationship is out of reach. On the other hand, mechanized, controlled (second-generation) experiments can resolve such causal relationships. However, the way to bridge the two types of experiments to answer archeological questions is still debated.</p> <p>Here we present a series of experiments that does just that: go from a highly controlled setup characteristic of material testing experiments to human actions. First, we used a material tester (Inotec SMARTTESTER) in a straight uni-directional cutting action. Second, we used a collaborative robot (Universal Robots UR10e) in a similar action. Third, we recorded a manually-guided uni-directional cutting action (human-like, i.e. not perfectly straight) on the robot with a custom-made software. Fourth, we introduced variability in the recorded movement: small random variation in position and force exhaustion. Finally, we performed the action manually.</p> <p>In order to isolate the effect of the movement itself, force, speed and acceleration (except for the manual experiment), as well as number of strokes and movement length, were kept constant. Additionally, both the tool and the contact material were standardized. The flint tools were cut to a standardized 45° edge angle with a diamond band saw. The contact material was synthetic bone plate. Such bone plates have similar physical properties to true bone, but make it easier to compare across experiments thanks to their homogeneity and flat morphology.</p> <p>We quantified use-wear polish on each sample at the end of the experiments and applied Bayesian modelling to test for the presence of significant differences.</p>	
<p><b>3</b></p>	<p><b>ABRASIVE WEAR FORMATION ON CHERT FROM DIFFERENT RAW MATERIALS: A CONTROLLED TRIBOLOGICAL EXPERIMENT</b></p> <p><b>Abstract author(s):</b> Rodriguez, Alice - Yanamandra, Kaushik - Witek, Lukasz - Behera, Rakesh Kumar (New York University) - Iovita, Radu (New York University; Eberhard Karls University of Tübingen)</p> <p><b>Abstract format:</b> Oral</p> <p>The identification of ancient worked materials is one of the fundamental goals of lithic use wear analysis and one of the most important parts of understanding how stone tools were used in the past. Given the documented overlaps in wear patterns generated by different materials, it is imperative to understand how individual materials’ mechanical properties might influence wear formation. Because isolating physical parameters is necessary for such an endeavor, controlled rather than replicative experiments and surface topography measurements are necessary to better grasp how polish formed on stone tools. Therefore, we used a tribometer to wear natural flint surfaces against five materials (bone, antler, two kinds of wood, and ivory) under the same force, speed, and angle over one, three, and five hours. The study aimed to test if there is a correlation between polish formation and the hardness of the worked material. We measured each raw materials’ hardness using nano-indentation test, and we compared the surface texture of the polished chert bits using a metrology microscope. The interfacial detritus powder was analyzed with a scanning electron microscope to look for abraded flint particles. We demonstrate that, contrary to expectation, softer materials, such as wood, create smoother polishes than hard ones, such as ivory.</p>
<p><b>4</b></p>	<p><b>OBJECT IMPERMANENCE: USING 3D MICROSCOPY TO ASSESS PERISHABLE MATERIALS THROUGH BONE MICROWEAR</b></p> <p><b>Abstract author(s):</b> Martisius, Naomi (The University of Tulsa)</p> <p><b>Abstract format:</b> Oral</p> <p>Ancient people undoubtedly used a variety of materials that are not often found in the archaeological record due to their tendency to decompose over time. Perishable materials such as animal skins or vegetal matter would have been used for clothing, footwear, containers, and other objects. Direct evidence for such items is often lacking, especially in very old deposits, but indirect evidence in the form of microwear traces can be found on more durable materials that came in contact with these items prior to deposition. Tools made out of bone are an ideal candidate for assessing wear from perishable materials because they tend to be used repetitively for long stretches of time, accumulating well-developed microwear traces.</p> <p>In this study, I employed 3D microscopic methods to quantitatively evaluate traces from three perishable materials on replicated bone spatulas, a common bone tool form used over millennia. All objects were made from Cervus elaphus ribs and were manufactured similarly using a ground stone. Next, each object was used for 40 minutes on one of three perishable materials (fresh animal skin, processed leather, and dry bark). Bones were scanned with a confocal microscope and evaluated using 3D surface texture parameters including surface roughness [Sa], peak curvature [Spc], and isotropy [Ist]. Quantitative measurements of the bone surfaces varied, but some patterns were evident and reflective of the differences in properties of the three perishable materials. The two different states of animal skin tended to round the upper reliefs of the bone surfaces, while bark flattened the surface reliefs. Fresh animal skin was the most abrasive of these materials and resulted in smoother surfaces overall. This study indicates that 3D microscopic methods have the potential for indirectly evaluating perishable materials that once came into contact with ancient bone artifacts, contributing to our understanding of ancient human behavior.</p>
<p><b>5</b></p>	<p><b>COMBINATION OF PETROLOGICAL, GEOCHEMICAL AND NON-USE-WEAR FOR THE TRACEOLOGICAL ANALYSIS OF THE MOST REPRESENTATIVE RAW MATERIALS FROM OLDUVAI GORGE (TANZANIA)</b></p> <p><b>Abstract author(s):</b> Alonso, Patricia (Instituto de Evolución Humana en África - IDEA; Centro Nacional de Investigación sobre la Evolución Humana - CENIEH) - Rios-Garaizar, Joseba (Centro Nacional de Investigación sobre la Evolución Humana - CENIEH) - Panera, Joaquín - Rubio-Jara, Susana (Centro Nacional de Investigación sobre la Evolución Humana - CENIEH; Instituto de Evolución Humana en África - IDEA) - Martín-Perea, David Manuel (Museo de Ciencias Naturales; Universidad Complutense de Madrid; Instituto de Evolución Humana en África - IDEA) - Pérez-González, Alfredo - Rojas, Raquel (Instituto de Evolución Humana en África - IDEA) - Domínguez-Rodrigo, Manuel (Universidad de Alcalá de Henares; Instituto de Evolución Humana en África - IDEA) - Santonja, Manuel (Centro Nacional de Investigación sobre la Evolución Humana - CENIEH; Instituto de Evolución Humana en África - IDEA)</p> <p><b>Abstract format:</b> Oral</p> <p>The traceological discipline has been characterised by a constant theoretical and practical revisionism, which has led to the application of increasingly precise methods and techniques that allow for more integrated analyses and interpretations to be developed from both reference collections and archaeological material. The progressive incorporation of a wide lithological variety in the study of use-wear traces, such as quartzite, quartz and volcanic rocks, has contemplated new methodological and technical challenges for their traceological analysis. The lithological variability recorded from the lithic industry found in the archaeological deposits of Olduvai Gorge, presents a favourable scenario for the combination of different analyses that allow a more detailed understanding of the formation and development of use-wear. In this communication we present, in a preliminary way, the experimental results obtained from the most representative raw materials (Naibor Soit quartzite and basalts) of the Bed II archaeological sites after the integration of petrological, geochemical and non-use-wear traces analyses to our experimental traceological study. The combination of these analytical methods permit us to characterise the micro-topography of each lithology and determine the degree of influence</p>

that the structural and mineral variability of each raw material has on the formation and development of the use-wear traces. In order to characterize more precisely the structural and geochemical influence on the formation and development of the use-wear traces, a wide range of activities as well as organic materials (wood, non-woody plants, animal carcasses and bone) have been included in the experimental reference collection. This organic variety in different states of preservation and under the exercise of different actions presents an important challenge for the characterisation of the formation and development of use-wear traces. Seeking a more concise characterisation of the use-wear traces, the incorporation of analytical methods such as petrology, presents significant advantages for the traceological interpretations.

6 **USE-WEAR ANALYSIS OF NEOLITHIC FLAKED AND GROUND STONE AXES AND ADZES FROM THE EASTERN GOBI DESERT**

**Abstract author(s):** Evoy, Angela (Cosumnes River College)

**Abstract format:** Oral

This paper presents results for the first use-wear analysis of Neolithic flaked and ground stone axes and adzes from the eastern Gobi Desert. The aim of this study is to define patterns of wear development on basalt and siliceous stone axes and adzes resulting from contact with various materials. I hypothesize that the axes and adzes were primarily used for tree felling and woodworking but include other economic activities. With limited paleoenvironmental reconstructions for this region, and no evidence for the presence of trees during this temporospatial period, hypotheses for the probable use of these tools were based on the body of ethnographic literature. To define patterns of wear on the archaeological assemblage, use-wear methodologies were adapted and incorporated into an experimental replicative program. An experimental comparative collection of basalt and chert axes and adzes was created. The experimental tools were used for tree felling, planing wood, hide scraping, butchering, and digging. Poplar was selected for tree felling and woodworking activities as palynological analyses indicates the genus *Populus* may have been an available arboreal resource in arid Northeast China during the late Neolithic (Demske and Mischke 2003). Replicated axes and adzes were analyzed at all stages of manufacture and use to discern the differential development of wear from contact materials. The experimental collection allowed for interpretation of use-wear traces on the assemblage of Neolithic axes and adzes from the eastern Gobi Desert. Results suggest that these tools were primarily used as tree felling and adzing tools but also include hide work and secondary use for plant pounding. The wear patterns identified here have the potential to broaden our understanding about the use of stone axes and adzes in other parts of arid Northeast Asia as these tools may have been used for similar activities.

7 **CONSISTENCY IS A BEECH – ON SOCKETED AXES, EXPERIMENTAL CONTROL AND LIGNEOUS CONTACT MATERIALS**

**Abstract author(s):** Thaler, Ulrich (Römisch-Germanisches Zentralmuseum - Leibniz-Forschungsinstitut für Archäologie)

**Abstract format:** Oral

Starting from the requirements of a specific experimental set-up, this contribution builds towards a discussion on the choice and preparation of a single representative contact material for use-wear experiments from a wider class of similar, yet non-identical prehistoric contact materials.

The set-up in question is a mechanical apparatus for the laboratory-based simulation of wood-chopping with bronze axe replicas. Strict experimental control is a prerequisite for isolating the influence of individual variables such as alloy composition on the formation and preservation of use-wear on copper-based artefacts. The concomitant need for consistency extends to the contact samples used. Characteristics of wood, however, as presumably the primary contact material for prehistoric axes, not only vary from species to species and tree to tree, but are also contingent on specifics such as the moisture content of a sample or even its (former) position and orientation in a tree.

Thus, the choice and preparation of wooden contact samples need to be guided by practical considerations as well as archaeological ones; the latter include, e.g., the ‘period appropriateness’ of a tree species based on its post-glacial expansion and the documented prehistoric uses of its wood for fuel, timber and portable artefacts. Practical considerations encompass the textural homogeneity of the wood of a given species and the ease or difficulty (as well as possible procedures) of pre-treatment, resulting, e.g., from the different anatomical characteristics of heartwood and sapwood species. Practical issues also extend to aspects such as the consistency of supply, with implications for reproducibility, and, linking back to archaeological criteria, the choices in previous experimental studies.

Making the case for European beech (*Fagus sylvatica*) in the given experimental context will highlight the potential complexity of an often underdiscussed element in traceological experimentation and contribute to the formulation of general criteria for single experimental contact materials.

8 **PLANT HARVESTING VARIABILITY DURING THE NEOLITHIC ANALYZED THROUGH TEXTURE ANALYSIS OF SICKLE GLOSS**

**Abstract author(s):** Ibáñez, Juan (Spanish National Research Council - CSIC) - Anderson, Patricia (CNRS) - Mazzucco, Niccolò - Pichon, Fiona (IMF-CSIC)

**Abstract format:** Oral

The Neolithic is a period of intensification in plant exploitation activities. Cereal harvesting in agricultural practices was carried out with flint or obsidian sickles. During the origins of agriculture, wild cereals were first reaped in natural fields, later cultivated and finally domesticated. Different species of cereals were cultivated and processed, as einkorn, barley, naked wheat or emmer. Flint tools could have been also used for processing domestic crops as part of threshing sledges. Moreover, other plants, as reeds or rushes, were reaped in order to use them for covering roofs, making mattings or basketry, among other uses. Thus, plant cutting traces, which after few hours of use generate macroscopic sickle gloss, show quite varied characteristics (more domed or flatter, more or less abraded...). In order to understand this variability, we use confocal microscopy and texture analysis. We intend to understand through experimentation how different conditions in plant cutting affect the characteristics of usewear polish, in order to unveil Neolithic technologies used for exploiting plants.

9 **AN INSIGNIFICANT OTHER? PRIMACY OF ‘FOUNDER CROPS’: ISSUES AND IMPLICATIONS FOR GROUND STONE USE-WEAR STUDIES IN SOUTHWEST ASIA**

**Abstract author(s):** Pedersen, Patrick (Centre for the Study of Early Agricultural Societies - CSEAS, Department of Cross-Cultural and Regional Studies, University of Copenhagen) - Arranz Otaegui, Amaia (Muséum National d'Histoire Naturelle. UMR 7209 - Archéozoologie, Archéobotanique: Sociétés, Pratiques et Environnements - AASPE; Centre for the Study of Early Agricultural Societies - CSEAS, Department of Cross-Cultural and Regional Studies, University of Copenhagen) - Richter, Tobias (Centre for the Study of Early Agricultural Societies - CSEAS, Department of Cross-Cultural and Regional Studies, University of Copenhagen)

**Abstract format:** Oral

This paper explores issues related to ground stone tool (GST) use-wear studies within the archaeology of the Epipaleolithic-early Neolithic transition in Southwest Asia (SWA). By surveying published use-wear studies within this field, we argue that the focus of GST use-wear in SWA contexts have had, and continues to have, an ‘unhealthy’ focus on a limited range of contact materials (‘others’). Studies of GST use and use-wear in SWA have tended to focus on plants normatively associated with the Neolithic transition in SWA and their food economies: cereals, legumes etc. both in interpretation of use-wear traces and in experimental programs. However, growing archaeobotanical evidence, as well as ethnographic evidence from across the globe, highlight the important role that plants other than the traditional Neolithic ‘founder crops’ played in past diets. One of these ‘other’ plant groups is underground storage organs (USO: rhizomes, tubers etc.). Recent work on material from two sites, Shubayqa 1 and 6. dated to the late Epipaleolithic Natufian to late Pre-pottery Neolithic (PPNA) periods of SWA, have further elucidated the role of USO’s. This study it draws on that recent data, coupled with GST data from Shubayqa 1 and 6 and our recent experimental study on tuber exploitation in the Natufian, to argue that though cereals and their processing may have been important, projecting their later primacy into the Paleolithic or even the PPNA risks clouding the nuances of past foodways. This ‘founder crop’ focus unfortunately results in a view mired by deterministic narratives. We wish to deflect this focus and nuance the normative, linear view of the cereals and GST ‘marriage’ as the quintessential core of the Neolithic transition. By divorcing this view we open up avenues to explore the more ‘insignificant’ other(s), materials lost by the narrow gaze of current GST use-wear studies in SWA.

10 **VARIABILITY OF GRINDING TRACES RECORDED ON BONE MATERIALS. EXPERIMENTAL AND TRACEOLOGICAL STUDY**

**Abstract author(s):** Orlowska, Justyna - Osipowicz, Grzegorz (Institute of Archaeology, Nicolaus Copernicus University in Toruń)

**Abstract format:** Oral

Grinding is one of the oldest known bone processing techniques. Archaeological finds indicate that in prehistory, various types of stone plates were used for grinding bone objects, the type of which (mainly crystallinity) could have a large impact on the morphology of traces formed on the worked surfaces. It is believed that the grinding process was often supported by additional treatments, such as adding sand or water, which influenced not only its efficiency but also the characteristics of the traces formed during its duration. For this reason, grinding and, above all, the possibilities of identifying its various variants during the microscopic analysis of prehistoric materials is still insufficiently known.

This problem was an impulse to undertake experimental and traceological studies, the main goal of which was to precisely, multi-faceted characterization and classification of functional traces resulting from grinding osseous raw materials on various types of grinding plates (i.e. various sandstones, quartzite, gneiss) using several techniques supporting the process (i.e. admixture in a form of water, dry and wet sand and softening of the bones). An answer was also made to the question of the influence of working time on the characteristics of this type of technological traces. The presented studies were designed to verify the scope of the possibilities of interpreting the traces that are the result of grinding, which are registered on prehistoric artefacts.

The project is financed by the National Science Centre, Poland (project no. 2019/32/C/HS3/00615).

BEHIND THE SCENES – TRIBOLOGY AND FRACTURE MECHANICS TO UNDERSTAND USE-WEAR FORMATION AND PALAEOLITHIC STONE TOOL USE

**Abstract author(s):** Schunk, Lisa - Calandra, Ivan - Gneisinger, Walter (TraCEr, Laboratory for Traceology and Controlled Experiments at MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM) - Marreiros, João (TraCEr, Laboratory for Traceology and Controlled Experiments at MONREPOS Archaeological Research Centre and Museum for Human Behavioural Evolution, RGZM; Institute for Prehistoric and Protohistoric Archaeology, Johannes Gutenberg University, Mainz, Germany; ICArEHB, Interdisciplinary Center for Archaeology and Evolution Human Behaviour, University of Algarve)

**Abstract format:** Oral

Traceological studies aim at the recognition and the identification of use-wear traces on artefacts in order to gain a functional interpretation of past human technologies. However, a visual identification and interpretation of the traces is known to be dependent on different mechanics involved, such as those related to the contact material, but also to the tool raw material and morphology, the use intensity and the performed task. Therefore, an understanding of the fundamental mechanics affecting wear formation is necessary to build reliable interpretations based on causation.

The cause-effect relationship between individual variables and the formation of use-wear can only be investigated by conducting controlled, second-generation experiments. In order to test individual variables, others have to be standardised. This applies e.g. to the contact material.

The here presented sequential second generation experiment tested for differences between soft and hard contact materials. In order to investigate the effect of the contact material on the wear formation, natural - pork skin and bone - as well as artificial contact materials - tissue pad and bone plate - have been used. Unidirectional cutting movements have been performed with a mechanical device using standardised tools. Force, velocity, acceleration and cutting stroke length were kept constant, allowing for an improved understanding of the formation of use-wear traces. Combined with qualitative and quantitative use-wear analyses, the data generated throughout the experiment did not only provide insights into the development of use-wear, but also into abrasion processes and fracture mechanics within the experimental setup. Concerning these aspects, no significant difference between the natural and artificial contact materials could be observed. Consequently, it can be argued that the use of standardised contact materials can be an advantageous choice in controlled experimental setups. Moreover, the experiment highlights the relevance of use intensity and duration in the context of wear formation.

THE CONTRIBUTION OF REPLICATIVE HUNTING TRIALS TO UNDERSTAND IMPACT CONTACT MATERIALS

**Abstract author(s):** La Porta, Alice (University of Manchester; University of Exeter)

**Abstract format:** Oral

The attempt to identify stone projectiles and their delivery systems through the analysis of impact traces has been a major goal in the field of traceology. However, less attention has been paid to the recognition of the impact materials against which projectiles can strike. Here we present the results of two different set of hunting trials, specifically designed to identify different hand-delivered weapon systems, that have also offered information on impact against specific materials. The influence that different variables, such as delivery modes, ballistic parameters, and impact materials, can have on the formation of macroscopic and microscopic traces during projectile impact was investigated. Integrated results between macroscopic and microscopic wear traces and experimental variables showed that clusters of trace patterns provided useful markers for determining impact against specific hard contact materials, such as bone and ground impacts. Whereas other soft contact materials, such as meat and flesh, were underrepresented. These results may contribute to the debate on trace formation in projectile activities and their representativity.

CONCLUSIONS AND QUESTIONS FROM AN EXPERIMENTAL AND USE-WEAR STUDY OF STONE BATTLE-AXES AND AXE-HAMMERS USED IN CONTACT WITH BONE

**Abstract author(s):** Roy, Amber (Newcastle University)

**Abstract format:** Oral

Antiquarians often argued that stone and flint artefacts, such as axes and arrowheads, were weapons, or symbols of a warrior elite. Initial interpretations of British Early Bronze Age stone battle-axes and axe-hammers were just that. This has remained a potential interpretation of the function of these implements despite its grounding in stereotypical assumptions rather than scientific analysis.

This paper draws upon data from the first large scale application of use-wear analysis and experimental archaeology on British Early Bronze Age battle-axes and axe-hammers from Northern Britain and the Isle of Man. It investigates two hypotheses, firstly that these implements were used as weapons and, secondly, that they were used in animal slaughter, with a single experiment using axe-hammer (in contact with bone and flesh) to strike pigs heads with a vertical thrusting chopping motion to test both hypotheses. It also draws upon experiments using battle-axes and axe-hammers in contact with wood and soil and stones.

Based on analogy with experimental use-wear formation, analysis of use-wear on over 100 battle-axes and axe-hammers revealed a small number were used in contact with bone and flesh and had no sign of contact with other tools or weapons. However, does this reflect their use as weapons or in animal slaughter, particularly when contact with multiple materials through combat was not tested experimentally?

PLAYER 2, READY. FIGHT! CONTROL, ACTUALISM, AND CONTACT MATERIALS IN PREHISTORIC COMBAT EXPERIMENTS

**Abstract author(s):** Gentile, Valerio (Leiden University)

**Abstract format:** Oral

This talk discusses the potential and the issues connected to the implementation of experimental archaeology and traceology applied to the study of prehistoric martial practices.

In testing combat situations with melee weapons, ‘the other’ plays a pivotal role. On one hand, contact material majorly affects both the type of trace generated as well as the degree of success in performing specific actions. On the other hand, contrary to some other activities, ‘the other’ in combat scenarios has its own active agency: in this context, ‘the other’ is ultimately the opponent, who contributes to trace formation with their choices and movements while also representing the final intended contact material (the target to be hit). This peculiarity poses a vast array of ethical and methodological issues: a.o. health and safety concerns or the feasibility of highly controlled experimental layouts when reproducing an activity in which not only materials but also multiple human users are involved as main variables.

This talk will delve into these issues while illustrating and critically evaluating a methodology for combat experiment which attempts to strike a balance between actualism and a degree of control necessary to ensure the reliability of the results.

WEAR-ANALYSIS AS THE MICROWEAR ASSEMBLAGE

**Abstract author(s):** Crellin, Rachel - Tsoraki, Christina - Harris, Oliver (University of Leicester)

**Abstract format:** Oral

Beyond the Three Age System (a research project at the University of Leicester, UK) has been exploring how we can bring microwear analysis and new materialist theory into conversation. In particular, the concept of assemblage, drawn from the work of Deleuze and Guattari, has proved useful. Assemblages are a way of rethinking the basic structures of the world. Rather than focusing on bounded entities, they instead consider how the world emerges through entangled relationships between humans and non-humans which are always in process. We have been approaching use-wear analysis through this theoretical lens and thinking of it as the ‘microwear assemblage’. First, because it always emerges from a heterogeneous collaboration between humans and non-humans (from microscopes to reference collections, cameras to gloves). Second, because it explores relationships between materials that press into and change each other (we term this affect in the language of assemblage). Third, because we see microwear itself as a process: wear-analysis is not a technique where we simply reveal how an object was used, it is a process of material engagement through which interpretations emerge.

Thinking about that process brings us to a specific set of experiments we have not conducted. As part of the project, we have carried out use-wear analysis on materials from Early Bronze Age burials in Britain. Analysis of one burial revealed that a collection of lithic grave goods (including repurposed older tools) had been used as a portable stone tool kit for working metals. Our analysis suggests that metals are the ‘absent present’ in this grave: gold and copper alloy both appear as contact materials that have left traces on lithic grave goods. Where could we go next? What experiments might follow from this realisation? The microwear assemblage reveals the absent ‘other’ and directs our action to future experiments.

SAME SAME, OR VERY DIFFERENT? LOOKING AT GRINDING TOOLS FROM DIFFERENT TASK FIELDS

**Abstract author(s):** Abar, Aydin (Institut für Archäologische Wissenschaften, Ruhr-Universität Bochum)

**Abstract format:** Oral

When it comes to the Metal Ages, grinding stones belong to the most understudied material remains found both on excavations and surveys, oftentimes remaining unpublished. This is particularly surprising as they play a fundamental role within many everyday activities, including food production. The situation is somewhat better in the context of mining archaeology, where questions about techniques, technologies and modes of labour traditionally play a more important role, and oftentimes finds tend to be rather sparse. First studies on grinding tools found in ore processing contexts indicate that functional reasons played an important role, when it came to the procurement of certain rocks as raw materials for grinding implements. Still, many questions remain unaddressed e.g. kinesthetics or work place organization and attribution of tools to certain task fields e.g. “grinding ore” or “grinding cereals” happens ad hoc, and is usually based on the surrounding context only.

The main aim of the presentation is to give a preliminary report on a case study carried out on several grinding stones from different Late Bronze Age sites in Trentino, including objects from settlements as well as ore processing sites. It provides a first glimpse into the question to which degree grinding stones associated with food-processing and ore-processing resemble each other and in which points they differ, from morphometry to macroscopic use-wear traces.

A ‘FAMILY OF WEAR’: EXPLORING USE-WEAR PATTERNS ON AD HOC BURNISHING TOOLS

**Abstract author(s):** Dubreuil, Laure (Trent University) - Robitaille, Jérôme (EHES) - Gonzalez-Urquijo, Jesus (Instituto Internacional de Investigaciones Prehistóricas de Cantabria, Universidad de Cantabria) - Marreiros, Joao (Laboratory for Traceology and Controlled Experiments - TraCEr, MONREPOS – Archaeological Research Centre and Museum for Human Behavioural Evolution. RGZM) - Stroulia, Anna (University of Southern Indiana)

**Abstract format:** Oral

Having traditionally focused on ‘formal’ tools (e.g., celts and grinding implements), the field of macrolithic studies has recently expanded to include ‘ad hoc’ implements (i.e., used without prior or with minimal manufacture). Use-wear analysis, in particular, has been instrumental in not only identifying ‘ad hoc’ tools, but also demonstrating the potential of these artifacts to illuminate a wide range of ancient activities. Among these activities is the burnishing of ‘plastic’ mineral materials such as mud, clay, or plaster carried out in construction, pottery production, and other contexts. This presentation focuses on pebbles used in an active abrasive manner to regularize, smoothen, and/or polish surfaces made of clay or mud material. We discuss several examples of such tools from the Natufian of the Southern Levant and the Greek Neolithic and compare their use-wear characteristics to those of both ethnographic and experimental specimens. We argue that: 1) the recurrent use-wear features observed on these tools may allow us to define a ‘family of wear’ characteristic of burnishing plastic mineral material in general; 2) further experimentations and quantification are necessary to better define the wear patterns associated with specific use contexts.

CONDUCTING USE-WEAR ANALYSIS AND EXPERIMENTAL RESEARCH IN SOUTH BRAZIL: LEGAL CHALLENGES AND POSSIBILITIES

**Abstract author(s):** Rodrigues, Felipe (University of Exeter)

**Abstract format:** Oral

Experimental archaeology and use-wear analysis in Brazil are at a crossroads when it comes to using native contact materials. On one side, there is a need to conduct experiments as contextually accurate as possible by using native materials, thus increasing the confidence of experiments. On the other side, archaeologists need to abide by the current legislation for preserving native fauna and flora which can be limiting to experimental research questions.

This paper discusses the current legal challenges posed by preservation needs and how to plan an experiment around it by presenting a use-wear analysis research conducted in South Brazil. In addition, it briefly presents two Brazilian laws (laws nº9.605 and nº11.428), which relate to environment preservation and directly affected the procurement of contact materials for this research.

This use-wear analysis research aimed to better understand the use of different lithic raw materials by Southern Jê people during pre-colonial times. For that purpose, eight different species of flora native to the Atlantic Forest biome were chosen as contact materials for a total of 32 actualistic experiments, based on historical descriptions of Southern Jê traditional crafts. The activities consisted of scraping, cutting, and sawing the plants to extract fibers, debark, split, smoothen their surfaces, or add a point to them. Although the aim of the experiments was to understand the wearing of the tools, the contact materials were pivotal in determining the tasks conducted.

This paper reports on the challenges faced, how they were tackled and shows it is possible both to align environment preservation interests and to foster the use of native contact materials for experimental use-wear research. This study can serve as an example for future research in Brazil and elsewhere where similar challenges may be present.

A GLOBAL 3D USEWEAR CHARACTERISATION OF PRIMATE AND HOMININ PERCUSSIVE TECHNOLOGY

**Abstract author(s):** Proffitt, Tomos (Max Planck Institute for Evolutionary Anthropology) - Arroyo, Adrián (Institut Català de Paleoecologia Humana i Evolució Social - IPHES-CERCA) - Reeves, Jonathan (Max Planck Institute for Evolutionary Anthropology) - Benito-Calvo, Alfonso (Centro Nacional de Investigación sobre la Evolución Humana) - Barrett, Brendan (Max Planck Institute for Animal Behavior) - Dogandzig, Tamara (Max Planck Institute for Evolutionary Anthropology) - Tan, Amanda (Durham University) - Falótico, Tiago (University of São Paulo) - de la Torre, Ignacio (Spanish National Research Council-CSIC) - Luncz, Lydia (Max Planck Institute for Evolutionary Anthropology)

**Abstract format:** Oral

Percussive technology has, in recent years, become an important avenue of research for understanding the wider tool use behaviours of early Homo beyond the production of sharp cutting flakes and tools. Recent discoveries of the earliest lithic technology suggest that percussive behaviour was probably an important component of the subsistence strategies of Pliocene hominins and possibly beyond.

Recent research has sought to better understand the range of percussive behaviours potentially undertaken by ESA hominins by describing damage patterns produced on tool-using non-human primate percussive tools. These studies have led to developments in analytical methods which allow the fine-grained quantification of use wear damage on percussive tools. To date, however, these studies have been applied to a small number of behaviours, primarily nut cracking. To explore the variability of use wear pattern across primate percussive stone tools it is important to apply these methods in a holistic manner to a wide range of percussive behaviours and tools.

Here we present the first comprehensive cross species study and comparison of percussive damage on hammerstones for all known tool using non-human primates and a range of Early Stone Age (ESA) percussive artefacts. By using a hybrid visual and 3D quantification of use wear patterns on the active surfaces of percussive stone tools we are able to present a detailed characterisation of the various damage patterns caused through different uses. Our results show that percussive damage characterisation is significantly affected by the objects on which the tool was used. The results allow for the identification of species and behaviour specific percussive use wear patterns which may be able to help interpret archaeological percussive technology. This study has also elucidated a complex interplay between the raw material type, percussive target and action motion for which future research must focus in order to understand these variables.

EARTH, WATER AND FIRE: APPROACHING LIVING HABITAT AND COMMUNITY LANDSCAPE MANAGEMENT

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Cantisani, Matteo (Institut für Archäologische Wissenschaften, Ruhr-Universität Bochum; Ruhr Universität Bochum, Zentrum für Mittelmeerenstudien) - Gheorghiu, Dragoş (Doctoral School, National University of Arts, Bucharest; Instituto Terra e Memória - Mação, Centro de Geociências da Universidade de Coimbra) - Von Rüden, Constance (Institut für Archäologische Wissenschaften, Ruhr-Universität Bochum)

**Format:** Regular session

The relationship of humans with natural resources keeps societies functioning yet also endangers environments and triggers social tensions. Although recent holistic approaches in archaeology have addressed the transformative role of resources in ancient societies, scholars in the humanities, social and natural sciences have not sufficiently explored the relationship in terms of sustainability. This resource-culture dynamic entangles humans and habitats in glocal histories of interrelationships. Habitat is a central concept here, for it implies a generative aspect which must be acknowledged in the development of sustainable non-Cartesian models in our relationship with the environment. This session aims to expand existing phenomenological, experiential, and praxitological discourses by offering an interdisciplinary venue to discuss this topic in terms of landscape management that both structures, and is structured by, sustainable habitats. Management is to be understood not only in relational terms but also through sensory experiences, dwelling within the landscape, and its symbiotic dimension. For this reason, the transformative role of natural resources in practices that shape landscapes will represent a particularly welcome topic, through case-studies and/or more theoretically-focused papers. Topics may include, but are not limited to, the appropriation of clays, water resources, and the central role of fire in making landscapes lived habitats. Therefore, papers will be very welcome which discuss pottery-making, (de)forestation activities, and building practices, or that explore the idea of anthropogenic spaces as living habitats also affecting ecological sustainability. More generally, archaeological research is encouraged from the intersection of philosophy, social and environmental sciences, and creative engagements with materials and resources that focus on the interrelationship of humans with their lived, experienced environments. The debate fostered by this session will offer a fresh understanding of these interrelationships, and new perspectives to discuss human resiliency and sustainable developments beyond the Cartesian separation of the human and natural.

ABSTRACTS:

COPING WITH A CROWDED HABITAT: HOMO AS PREY, PREDATOR, AND IMITATOR

**Abstract author(s):** Bouissac, Paul (University of Toronto)

**Abstract format:** Oral

The imagination of Homo surviving and evolving in a natural environment all too often glosses over the fact that these hominins and early humans had necessarily to share their niches with other organisms competing for the same vital resources and offering various solutions to similar challenges. While no human groups could ever survive far from a regularly accessible source of water and deprived of some form of protective shelter, they had to contend in addition with powerful animals that had equal claims to these resources. The representation of the prehistoric environment as mostly providing mineral and vegetal resources, and some occasional live prey (the hunter-gatherer model), is a simplistic theoretical vision. All the habitable niches on the earth are crowded with organisms that share the same vital imperatives ruled by hunger. Early humans were not the first inhabitants; they always found, wherever they went, predators, pests, and parasites for which they were natural prey. In fact, they had evolved in constant interaction with these organisms that offered them examples of longstanding adaptations through some modifications of their environment that greatly pre-dated the emergence of Homo. Cognitive competences such as “theory of mind”, analogical thinking, and imitative behavior would naturally lead early humans to shelter exploitations, arboreal constructions, digging and damming, clay use, and even ways of weaving. The physical and mental lives of early humans must be imagined as entangled with a diverse and crowded animal population teeming with adaptive activities. This paper will review some of the main examples of landscape transformations due to animal industry, from termites to beavers. This perspective should contribute to situate landscape management by humans in a wider biological context.

2

THEIR HABITAT WAS A LIVING ORGANISM: HUMANS/NON-HUMANS ARCHITECTURAL ENTANGLEMENTS IN THE HISTORICAL LANDSCAPE OF ICELAND

**Abstract author(s):** Vaquero, Pablo (University of Glasgow; University of Granada)

**Abstract format:** Oral

Much thought has been given to the study of how humans managed natural resources, shape the landscape, and were shaped by it. Many debates around this topic have focused on economic production and subsistence. By contrast, less attention has received the question of how past cultures created their living-space, their habitat. No doubt, this happened in a constant interrelationship between humans and non-humans; but the scale of impact, sustainability, and disruption vary from place to place and historical period.

Human Ecodynamics (HE) and Historical Ecology offer the possibility of approaching the topic from a complex and integrative perspective. Both propose the study of the human-natural system(s) through space-time, asserting the bi-directional agency of humans and non-humans. This school of thought aims at understanding synergies between different entities by recognising the existence of non-linear dynamics of causality and hierarchical/heterarchical scales. In this sense, it widens our conceptualisation of landscapes and, to be sure, habitats.

In this paper, I apply this vision by focusing on the historical feature of the Icelandic habitat par excellence: turf houses. They represent rural architectural elements that have stood for more than a millennium as the home of Icelanders. In the last century, however, they have been abandoned both architecturally and ontologically -i.e. as human-decentered, vernacular, projects. These elements were built thanks to the constant interrelationship of biotic (including humans) and abiotic entities - a constant flux of matter through time-space. The habitat of Icelanders can be conceived thereby as a living, symbiotic, organism. Recognising these entanglements and their meaning, I argue, is fundamental for interpreting the historical complexity of rural landscapes. It is through this lens that we can think outside of our current frameworks and realise the existence of more sustainable ways of creating habitats and, by extension, managing landscapes.

3

LONGING FOR ASSEMBLY: THE SIGNIFICANCE OF BEINGNESS OF PLACE

**Abstract author(s):** Dods, Roberta (University of British Columbia)

**Abstract format:** Oral

Our evolved and evolving responses to both socio-cultural and biological drivers of change can be seen in the archaeological record. This record is our tome of becomingness. We came to defining our specific spaces/places (niche / habitat / Ecotope, even territory, etc.) through nouns prefaced to -scape (sea-, water-, land-, town-, city-, sound-, etc.) thus creating infinitesimal to expansive clusters of meaning many with flexible, indeed nebulous, boundaries. These spaces can extend from the theoretical construct of hypervolume (Hutchinson 1957), the n-dimensional environmental space encompassing a focal organism (here the genus Homo), population or species in a hypothetical referential frame or imaginary volume to existential musings of conceptual frameworks for metaphors (dreamcatchers, saṃsāra [Bhavacakra] or mandalas) of our becomingness as situated in the cyclical events that are “refracted through various external factors... mediated between the physical and social worlds of humans”. Our places in worlds of time and space are “not merely ‘revealed’ and ‘discovered’ in a social and political context” but rather are “constructed and negotiated” (Colwell-Chanthaphonh and Ferguson 2006: 148; 159) through deep observation that can, fundamentally, include and then, through contemplation, transcend. We are challenged by both adaptation (biological) and adaptability (behavioral) as we consider the various drivers that have shaped our beingness. Effectively, from our evolving identity, we discovered an understanding of the composed unity of the intricacies of multiple biotic, socio-cultural and spiritual communities. We have come to recognize that our worlds became variously changing -scapes of existence defining our layered identities from self to cultural components of living in congress.

4

THE TOUCH OF THE DEEP: NOVEL ENGAGEMENTS WITH MARINE BEINGS IN THE SOCIAL SPACES OF MINOAN CRETE

**Abstract author(s):** Anderson, Emily (Johns Hopkins University)

**Abstract format:** Oral

This paper examines how certain forms of Cretan Bronze Age material culture afforded innovative engagements between people and nonhuman organisms of the sea by “drawing them up” and into the above-ground spaces of Minoan sociocultural experience. I examine two case studies. First are early wall paintings from the palace of Knossos, where sponges were covered in paint and then pressed upon the surface of the wall. I am interested in the indexical relationship between the sponges, organisms of the sea floor, and the wall “decorations”, and how resource extraction by skilled figures (sponge divers) mediated this link. The second case study concerns a corpus of ceramic vessels crafted with high relief renderings of sea organisms on their surface. I consider how the vessels brought people a new haptic engagement with sea forms that literally brought into their hands. Both of these indicate ways in which the sea was novelly made present within the lived experiences on the land.

5

RECONSTRUCT THE LATE NEOLITHIC AND THE BRONZE AGE VILLAGE THROUGH GEOARCHAEOLOGY: CASE STUDIES FROM ITALY AND SOUTHERN FRANCE

**Abstract author(s):** Peinetti, Alessandro (Laboratoire Archéologie des Sociétés Méditerranéennes, UMR 5140 (CNRS, Univ. Paul Valéry Montpellier 3; LabEx ARCHIMEDE - programme IA- ANR-11-LABX-0032-01; Università di Bologna)

**Abstract format:** Oral

Archaeological sediments are considered as both an environmental and a cultural archive of past societies and human practices. This theoretical advancing is also due to the development of Geoarchaeology and, in particular, to the exceptional development of soil micromorphology adapted to archaeological contexts in the last forty years. Soils and sediments record human activities and furnish data about the use of space, dwelling activities and landscape use through the analysis of formation processes of archaeological deposits and occupation surfaces.

Between the end of the Neolithic and the Bronze Age, settlement sites with different forms are observed between Southern France and Italy. These variability concerns not only the shape and the organisation of the built space, or the environmental and topographic context of settling, but also the development and preservation of stratification of each site. All these settlements are described and considered as villages, but such variability in terms of forms reflects different lifestyles and different way to organize and manage the built environment.

In order to explore this variability, we choose to compare three different sites: La Capoulière (Southern France, Late Neolithic); Via Ordieri-Solarolo (Northern Italy, Middle Bronze Age); Mursia (Pantelleria, Early Bronze Age). In each site, we carried out a spatial geoarchaeological analysis. Soil micromorphology is the main analytical tool adopted for this work. Some examples from these researches will be shown to explore some topics as: (1) the procurement and use of pedo-sedimentary resources for building; (2) building practices; (3) procurement and the management of other goods for production and consumption activities; (4) the use of space and the organisation of inhabited areas.

Through these different examples, the constants and the variables of the way to inhabit the village and the social and economical implications of different lifestyles recorded by archaeological sediments will be explored.

6

CLAY, STONES AND SHERDS - DWELLING IN THE NURAGIC LANDSCAPE OF SANT’ANTIOCO/SOUTHERN SARDINIA

**Abstract author(s):** Usadel, Marie - Klingenberg, Tim - von Rüden, Constance (Ruhr University Bochum)

**Abstract format:** Oral

The incorporation of raw materials as resources plays a major role for understanding the act of dwelling in a landscape. However, this process cannot be described as a one-sided act of environmental exploitation or control by a human community, rather it has to be understood as a mutual entanglement of humans and materials in a non-cartesian way. Therefore, we not only aim to carve out how the daily practices of the inhabitants of Sant’Antioco are assembling the different materials and human actors involved through time, we also aim to bring the sensory engagement of the human actor into the foreground of the discussion. Hence, the presentation will focus on the building activities and specific architecture as well as on the pottery production of the Nuragic period and question their specific choice or disregard of materials while taking into consideration their places within the landscapes. Moreover, it wants to discuss the generative abilities of material and immaterial resources to enable a certain sustainability and when this equilibrium might be destroyed.

7

STARTING FROM SCRATCH? APPROACHING RESOURCE MANAGEMENT IN IRISH VIKING TOWNS

**Abstract author(s):** Boyd, Rebecca - Stone, David (University College Dublin)

**Abstract format:** Oral

Ireland, prior to AD800, was entirely rural. The foundation of Dublin, Ireland’s first town, required an adjustment in attitudes to lifestyles, but also to resource procurement and management strategies.

How did this new urban population sustain itself? Its environment was almost entirely organic. With the exception of occasional stone monumental structures (churches or town walls), domestic buildings were made of wood, thatch and other natural materials (straw, brushwood, clay, stone etc). Sourcing, supplying and managing these resources must have been of major concern for the townspeople. This takes on extra prominence when considered in the light of the frequent need for replacement of individual building materials – roof supports, thatch, bedding material – and the regular replacement of entire structures at any point in time. These questions of resource procurement have been indicated in Viking Age towns in Ireland through sporadic environmental approaches within developer-led archaeology but they have not been seriously addressed.

In this paper, we present an overview of some questions which we see as relevant here. We also survey the existing evidence particularly noting the value of commercially derived archaeological data.

Urban settings and urban-rural relationships require us to re-evaluate what and how we investigate those intersections between human and environment and between archaeology and interpretation. These datasets and avenues of investigations will lead to new insights into the interrelationships between urban and rural habitats and landscape and resource management strategies in the Viking Age.

8

DWELLING IN THE CHALCOLITHIC: THE RELATIONSHIP BETWEEN SETTLEMENTS AND THE ENVIRONMENT

**Abstract author(s):** Gheorghiu, Dragos (National University of Art; ITM Macao)

**Abstract format:** Oral

In South Eastern Europe, during the Chalcolithic, human settlements used a complex relational strategy with the geographic environment, based on a control system that used both a series of ritual separations, and the recombination of the materiality of the surrounding landscape.

The positioning of the settlements between dryland and water required numerous ritual and functional separations, both between the closed tell - settlement and the wilderness or the necropolis, as well as between the tell and its subordinate, seasonal settlements. The separation from the landscape was also one based on substance: the settlement was the result of the processing of the “wild” materiality and the production of a new one, that of composite materials, by combining the clay with water, plants and [cyclically] with fire.

The compact organization of the interior of the tell-settlement required a certain type of relationship with fire, as well as that required by the internal organization of the house. All these material relations can be found in the symbolism of the objects of the interior space of the house, which support, on a micro-scale, the relations between the act of inhabiting, water, clay, plants and fire.

9

MODELLING FOOD CONSUMPTION AND WOOD UTILISATION AS INDICATORS FOR PERCEPTION, COMPETITION AND LANDSCAPE MANAGEMENT

**Abstract author(s):** Boenke, Nicole (Ruhr-Universität Bochum)

**Abstract format:** Oral

The importance of food supply and the dependency on wood have been outlined by researchers from the fields of archaeology and archaeobotany for decades. Without a solid basis represented by those two factors, the establishment of complex structures is close to impossible. This specifically applies for specialised organised communities as we particularly encounter since the Metal Ages. Therefore, it is not surprising that in order to emphasize the development of ancient societies towards 'modern' 'industrialized' economies, archaeologists often argue in patterns of superlatives such as economic efficiency, enormous (trade) distances or landscapes devastated due to the exploitation of resources. In fact, this is proofed just in few cases, but unfortunately those results are frequently taken to create an image of ancient communities in general. But I would rather see the examination of extremes as one of the possible scenarios. Lacking 'attractiveness' is not the only reason for the rareness of studies focused on the individual scales and on private or small-scale common decisions, which were based on the taste or other personal preferences of ancient people. Unfortunately, individual experiences are much harder to verify than large bulks of statistic data. For the reconstruction of living environments data modelling is a principal and very effective tool to be applied. However, at this point another principal question arises: how to proof all the ancient motivations not easily fitting in (economically) rational patterns?

Based on the archaeological results of an Iron Age Salt mine in the Alps the paper takes a look on the constructed antagonism between mining and sustainability as well as on decisions apart from reasonable motivations. Other case studies are picked up to show implications on food and wood utilisation in Europe and Western Asia.

10

LIVING ON A SMALL VOLCANIC MEDITERRANEAN ISLAND: THE CASE OF USTICA AND ITS PREHISTORIC PALEOENVIRONMENT

**Abstract author(s):** Speciale, Claudia (Istituto Nazionale di Geofisica e Vulcanologia, Naples; University of Las Palmas, Gran Canaria)

**Abstract format:** Oral

This paper interprets the first analytical data to emerge from the island of Ustica (north-western Sicily, Italy) during the Neolithic and the exploitation and management of the limited local resources starting from the first human occupation in the mid-5th millennium BC. The small volcanic island of Ustica experienced several dynamics of occupation and abandonment, until the very last phase of colonization in the mid-17th century AD. The recent investigation of the site of Piano dei Cardoni (4600-4200 BC) attests the presence of human communities in some areas of the island, that probably represented a bridge in the obsidian trade route and exchanges between Aeolian islands and western Sicily. The analyses of plant macro-remains and the comparison with data on local vegetation obtained from historical literary sources and modern flora checklists show the disappearance of some woody species, today extinct or only occurring as re-introduced trees. The onset of agro-pastoral practices in the mid-5th millennium BC, testified by the archaeozoological dataset, brought about significant changes to the local pristine plant communities, probably once characterised by evergreen woodland. Local human communities exploited local and imported raw materials and objects, as attested by the analyses on lithic tools (flint, obsidian and other volcanic rocks) and pottery, showing an exploitation of several local resources throughout the island and a reliance only on specific exotic materials like obsidian. Recent analyses on the human bones from the site are highlighting origin and entity of the human population occupying this territory for the first time.

11

FROM SPACE TO PLACES, FROM LANDSCAPE TO BUILTSCAPE: RECONSTRUCTING PREHISTORIC ARCHITECTURES IN CENTRAL SICILY

**Abstract author(s):** Giannitrapani, Enrico (Confederazione Italiana Archeologi; Arkeos - Servizi integrati per i Beni Culturali)

**Abstract format:** Oral

Landscape is the geographical and political space where human history is expressed in a relationship of mutual conditioning with nature. It is a dynamic entity, a container of individual and collective memories, as it bears the 'signs' of the history of its transformations. To study the landscape is to understand its phenomenological value, that is the cognitive, symbolic and 'political' ability to interact with the environment. This determines the development of complex modes of production and reproduction of the material conditions of human communities. The identity of places is always built through complex relations, conflictual and dialectical, a constant relationship with alterity. Spatial experience is not innocent and neutral but produces hierarchical power relations based on age, gender, and social position. It constitutes a contradictory and conflict conscience through which individuals act. Every interaction between people and the natural environment creates a 'built' environment: one of the landscape's key transformative processes is architecture. It aims to organise the space where human beings live, transforming natural spaces into humanised places, into a builtscap. To build a house is a social process, determined by the cultural and historical conditions to which it belongs. If providing shelter is the house's passive function, then its active purpose is to create an environment suitable for a community and its members. Houses are social and 'political' units of organization of space. As a place of residence, production and consumption, the house expresses different meanings: family structure, social and production relations, interactions with natural resources. Architecture, then, is an ideological means to structure human society. After a synthetic theoretical discussion on spaces, places, and houses, recent researches on prehistoric central Sicily's domestic architecture will be introduced as a significative case study.

12

SENSES AND SOCIAL NEGOTIATIONS IN THE AMARNA WORKMEN'S VILLAGE

**Abstract author(s):** Rocha da Silva, Thais (University of Oxford; University of São Paulo)

**Abstract format:** Oral

The investigation of ancient Egyptian houses has paid little attention to the sensory elements that shape our lived experience. Houses have been investigated through typologies and an economic perspective that frames social life as a consequence of (re) production of goods and people. In this presentation, I explore how material culture can inform us about the interplay of the senses on social interaction within the domestic sphere in the Amarna Workmen's Village, a settlement built to house the workforce engaged on royal projects in the New Kingdom. The village was established by the Egyptian administration at the edge the desert, distant from the Nile but still connected with the city. This location demanded regular deliveries of supplies and water from the government to the local inhabitants and a spatial arrangement of the domestic space that could keep the place functioning. I show how an approach that integrates the architectural features of the village with the distribution of domestic facilities (food preparation, water storage) reveal a different sense scape, that where we can perceive social negotiations.

CONFLICT ESCALATION AND DE-ESCALATION IN URBANITY

**Theme:** 4. Globalisation and archaeology

**Organisers:** Loy, Anna (ROOTS Kiel) - Alliata, Victoria (CAU Kiel) - Cembrzyński, Paweł (ROOTS Kiel) - Zeviani, Camilla (University of Cambridge)

**Format:** Regular session

Urbanisation is a process in which people have to cope with changing conditions and increasing complexity. Such conditions not only involve an increase of population numbers and density, but also social competition, a competition for resources and development of new modes of interaction.

Urbanity can be seen as a lifestyle or interaction system which addresses issues of continuously increasing complexity and necessarily requires corresponding mechanisms of conflict resolution and de-escalation. Both escalation, potentially leading to the annihilation of at least one of the conflict parties, and de-escalation, potentially leading to cooperation, may present themselves as changes in this system. Inevitably different elements of society will be differentially affected and may be caught somewhere between fluidity and resistance.

Given the high potential for competition within urban places, we might expect an interrelation between urbanity and violence. However, urbanity apparently exhibits a rather low frequency of violent conflict. Urbanity is thus a telling example of successful resolution of conflict escalation and de-escalation, a topic which is essential for the understanding of resilient urbanity and urbanisation.

This session may evolve around questions such as:

- How can processes of escalation and de-escalation be found in the material record?
- What evidence do written sources introduce?
- Which insights can ethnography bring to the debate?
- Are there other possible sources of insight?

In this session, we aim for contributions addressing the identification and analysis of conflict escalation and de-escalation within urban places and processes, and especially the analysis of de-escalating strategies in urban contexts. We want to find out, how

415

people cope(d) with strains on personal and communal identity in urbanity. Contributions from prehistoric and historic archaeology, from sociology, from ethnography as well as from other fields of research and a global perspective are warmly encouraged.

ABSTRACTS:

1 CONFLICT PROCESSES AND URBAN PROCESSES INTERCONNECTED

**Abstract author(s):** Alliata, Victoria (CRC 1266: Scales of Transformation Kiel) - Loy, Anna (ROOTS Cluster of Excellence Kiel) - Nakoinz, Oliver (Institute of Pre- and Protohistoric Archaeology, Kiel)

**Abstract format:** Oral

Urbanity can be understood as a process that represents a balance between centripetal and centrifugal forces, and includes a set of practices and structures that keep this balance in a dynamic development.

While centripetal forces are represented by interaction opportunities, centrifugal forces are rooted in system complexity, community thresholds, and conflicts. These conflicts arise from unequal opportunity distribution, different individual interests and the sheer scope of diverse interaction possibilities between individuals with different interests in an urban system. Conflicts can be described as processes of escalation and de-escalation, with conflict potential representing an important pre-condition.

Urban conflict potentials as described above require specific solutions and specific strategies. With this paper, we want to explore the interrelationship of conflict processes and urban processes. Which strategies of conflict solution, of coping with conflicts and conflict prevention are visible in the archaeological record of urban and proto-urban sites? Do conflict de-escalation or solution strategies shape the urban profile of a place? Can a failed conflict solution compromise or even stop the urban process? The examples discussed here will include Heuneburg, Manching, and further urban and proto-urban centers in Europe.

2 URBANIZATION HALTED: REGIONAL POLITICS AND DEMOGRAPHIC CHANGES BETWEEN THE 7TH AND THE 6TH CENTURIES BC

**Abstract author(s):** Zeviani, Camilla (University of Cambridge)

**Abstract format:** Oral

The presence of cities has been traditionally connected to concepts of civilization, the urban form being the head of a hierarchy and the final result of an evolutionary process (Stage Theory). The Classical world and its examples of stable, long-standing urbanism had provided the paradigm for the definition of urbanized societies: more recent analysis in other parts of the world have proven, however, the existence of urban variabilities that distance themselves from the paradigm. Representing the earliest urbanized society in Western Europe, Etruscans present a crucial case study: through archaeological surveys, it is now possible to quantify different urbanization patterns, as well as drawing comparisons of strategies of control enacted by each place of power. Rural settlements represent leftovers of the rural structure that supported this expansion and assured the success of urbanization. However, urbanization was not unanimously embraced as the preferred social structure. Elements of conflict and resistance can be examined in smaller and short-lived enclaves of political power that tend to emerge in the formative period of city centers, usually connotated by religious/ aristocratic values and ideology. One of these is the site of Poggio Civitate (Tuscany, near Siena). Occupying a frontier, its function has been subjected to different interpretations, which lacked however data more recently acquired in surveys led in the area. By analyzing and properly identifying the nature of this Etruscan site, this paper seeks to show that urban development could often be limited by the activity of traditional elites and by the complex management of regional politics. It will highlight how the rural population was strictly dependent and tightly tied to the center, which restricted its development and capitalizing on its economic production until it was dismantled by other, fully urbanized regional powers.

3 RELATIONAL URBANIZATION IN THE MYCENAEAN GREECE: CONFLICT DE-ESCALATION IN LATE BRONZE AGE PALATIAL SETTLEMENT NETWORKS

**Abstract author(s):** Zeman, Piotr (Adam Mickiewicz University in Poznań, Faculty of Archaeology)

**Abstract format:** Oral

Mycenaean civilization emerged on the Greek mainland in the first half of the second millennium BC, and gradually dominated the Aegean. During the 14th century BC (Late Helladic IIIA), after a period of formative rivalry between various Early Mycenaean centres, it entered the so-called palatial period. It was an era of gradual centralization of administration and economy around the palaces, monumental residences of a ruler and his bureaucratic administration. The appearance of the palaces led to the development of palatial towns, i.e. settlements consisting of the palace and the lower town surrounding it. Those towns served as key nodes of urbanized, functionally and structurally organized regional settlement networks. They were political, economic and religious capitals of Mycenaean palatial states. Through the distribution of elite burial forms and monumental architecture, and both written and material records related to economy, we can see how the involvement of the palatial states extinguished the constant conflict and rivalry between competing local elites, that were characteristic of the Early Mycenaean period. Instead, various regional centres, organized in a hierarchical system, were now dominated by the palatial town, often serving a specific function within the palatial economic system. In the same time the ruling palatial elite applied various strategies of de-escalating social tensions, mainly through redistribution of goods and land, massive communal feasts and strict control of the circulation of prestigious items. In this paper I

try to explain those processes, by discussing formation of palatial towns and their regional settlement networks in the regions of Messenia and Argolid. Despite regional differences between various Mycenaean centres, some general conclusions are also drawn regarding de-escalation of conflict in the urbanized palatial settlement networks of the Late Bronze Age Greece.

4 SETTLEMENT PATTERN AND SOCIAL DYNAMICS IN NORTHERN ABRUZZO BETWEEN THE 8TH AND THE 6TH CENTURY BC

**Abstract author(s):** di Giovanni, Andrea (Università La Sapienza, Roma)

**Abstract format:** Oral

Northern coastal Abruzzo is still today a territory difficult to investigate from various points of view. It is enclosed between territorially and culturally defined area, as it is bordered by the mountains to the west, the Adriatic to the east, the Picenum (with the Tronto river as a natural limit) to the north and the territory of the Marruccini to the south of the Pescara river. Moreover, an inner border line is defined by the location of sanctuaries placed between different population. Archaeological investigations have brought to light many sites that have never been fully investigated, leaving the understanding of the territory incomplete. Indeed, between the end of the Bronze Age and the early Iron Age (8th-6th century BC), the general trend of settlements is to move toward high visibility and controlling places in the landscape (incastellamento), different local response then the Tyrrhenian-style urban forms. This denotes the need for territorial control in an area morphologically divided by medium height hills and small rivers, with settlements of different sizes built on plateaus (as for the Umbrians and Picenes), on single and multiple hills with the presence of often more than one relative cemetery. It is important to note that the area is a meeting point for at least four different cultural groups identified in historical times as Pretuzi, Vestini, Marrucini and the ager Hadrianus ( not identify to any said population).This presentation intends to investigate the causes and the dynamics of internal conflicts that gave origin to the need to build settlements and outposts on high ground through the analysis of the unpublished data coming from Atri's site and their role in the wider frame of the settlement pattern of the area.

5 VIOLENCE AND CONFLICT DE-ESCALATION IN PRE-ROMAN CENTRAL APENNINE (6TH – 5TH CENTURY BC)

**Abstract author(s):** Scarsella, Elena (Cambridge University)

**Abstract format:** Oral

This paper aims to investigate the apparently counterintuitive role of armed conflict in the de-escalation of social conflict in the mountain societies of Archaic Abruzzi, Central-Apennine. Mediterranean mountains are an interesting landscape under many aspects, and they contribute to the shaping and the formation of the unique identity of the populations inhabiting them. This paper will approach the topic from a landscape perspective, without excluding the data coming from material culture, but integrating them within a broader, holistic, framework. Indeed, the constraints of the environment, the limitations of the climate, and the rugged nature of their morphology create the basis for a fragmented human landscape. Phenomena of centralisation and urbanisation that developed on the Tyrrhenian coast and in Greece already by the 7th century BC, happened in the mountainous Abruzzi only much later and under different circumstances, namely the Roman influence. Until then, on the other hand, the settlement pattern obeyed rules dictated by the landscape and the peculiar social structure of the area. Organised around a central hillfort and focussed on the defence and control of mountain passes that connect the valleys, the settlement pattern here relied on a complex system of small hillforts and outposts, often very far from each other. The cemeteries reflect this pattern: together with extensive burial sites on the plains, small necropoleis were often associated with isolated outposts and smaller settlements. Within this complex territorial system and based on the abundance of functional weapons and osteological traces of widespread violence among male adults, conflict seems to be a fundamental aspect of the delicate balance of power of the area, at least from the beginning of the 6th to the first half of the 5th century BC, namely the formative years of the people that will be later called Vestini by the literary sources.

6 SPACES OF INEQUALITY AND CONFLICT IN URBAN HISTORIOGRAPHY OF THE MIDDLE AGES

**Abstract author(s):** Müller-Liedtke, Catharina (ROOTS Cluster of Excellence, CAU Kiel)

**Abstract format:** Oral

In the urbanization boom in Central Europe, which lasted from the 11th to the 15th century, the inhabitants of the cities consolidated into burgher communities. These communities developed their own intrinsic moral values and agency, which has been repeatedly quarrelled over. In this progress they created a demarcation that was also perceived from the outside. This presentation will investigate spaces of inequality and conflicts within urban historiography from the 13th to the 15th century. In this regard, the focus is on the hermeneutic textual analysis of urban conflicts as a cause and consequence of social inequality. How were urban conflicts presented? Which urban conflicts are present? How are these conflicts spatially located and how were the conflicts perceived by different individuals? Finally, examples from urban historiography (Augsburg, Cologne, Nuremberg, Strasbourg) will be explored to discuss whether they have relevance to archaeological examples. How can the literary description of a conflict and the material findings be related to each other? To what extent can a text-based perspective be supplemented with material access from archaeology and vice versa?

7

VIOLENCE-RELATED TRAUMA AND SOCIAL CONFLICT AT PRE-HISPANIC ANDEAN CITIES VS. THE OUTLANDS: INSIGHTS FROM BIOARCHAEOLOGICAL BIG DATA

**Abstract author(s):** Scaffidi, Beth (University of California, Merced) - McCool, Weston (University of California, Santa Barbara)

**Abstract format:** Oral

Many cities and sociopolitical centers of the pre-Hispanic Andes were mixing pots of people hailing from disparate geographic origins and with distinct practices, preferences, and individual and communal identities. For example, the Inca Empire of the late pre-Hispanic Andes is known to have practiced the forced and heavily incentivized resettlement of ritual practitioners, laborers, military conscripts, and other groups, united in the common cities of the empire. Earlier states and empires may have enacted similar policies. As these peoples came together into an urban setting from disparate places with sometimes incongruous cultural systems, did these social difference lead to tensions that boiled over into violent conflict?

This paper leverages a bioarchaeological big data approach to exploring the relationships between the frequency and type of violence-related cranial trauma (a proxy for interpersonal violence), site sociopolitical organization, settlement/city size, geographic location (plotted in GIS), and evidence for violent ritual like human trophy-taking or sacrifice. Cranial trauma rates are lower for burial samples from large settlements and cities relative to those from the provinces. This data should be interpreted cautiously given that burial samples do not reflect natal individuals injured and buried outside of the site, and since antemortem wounds could have occurred in other locations. Nonetheless, the patterns observed here suggest that Andean cities maintained systems of de-escalation that mitigated violent interpersonal conflict within large settlements and cities. Violent, sometimes public spectacles may have comprised a social order that helped to ease conflicts in multi-ethnic urban settings.

8

THE ETHNOGRAPHY OF CONFLICT ESCALATION AND DE-ESCALATION

**Abstract author(s):** Stoddart, Simon (University of Cambridge; University of Kiel)

**Abstract format:** Oral

This presentation will examine the social processes of conflict escalation and de-escalation in settlement nucleations of different scales, with the assistance of ethnographies provided by Goody, Kopytoff and Boissevain. The work of Goody will be deployed to study the key issue of succession between different political authorities and conflict occurs and is reduced at this very sensitive moment of transition. The work of Kopytoff on the internal frontier will be assessed to understand how issues of conflict are resolved in a landscape setting, developing over time. Finally, the work of Boissevain will be examined to understand how these issues play out in the intensity of small scale societies, encountered with a high frequency on islands but also applied to larger territories. Finally, these models will be explored to see whether they have relevance to archaeological examples which will be drawn from European data, ranging from the Neolithic to the Iron Age.

318

HOW CAN METAL CORROSION PRODUCTS CONTRIBUTE TO ARCHAEOLOGICAL RESEARCH? - ARCHAEOMETALLURGY@EAA, PART 1

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Rose, Thomas (Department of Bible, Archaeology and the Ancient Near East, Ben Gurion University of the Negev; Scienze dell'Antichità, Sapienza - Università di Roma) - van der Stok, Janneke (University of Amsterdam; Metals Inc.) - Peters, Manuel J. H. (Politecnico di Torino; Universidade de Évora)

**Format:** Regular session

In archaeology, the outer surface of a metal artefact is increasingly valued. Corrosion products and adhering material often contain valuable information (e.g. ghost structures) and can significantly contribute to the artefact biography. In the conservation sciences, alteration layers are regularly examined to gain information about the local environment and the alloy with the aim to design the best treatment possible.

With the spread of affordable and easy-to-use portable equipment like pXRF, the number of analyses from this outer surface is increasing and curators become even more critical when it comes to invasive sampling. Using corrosion layers for analysis instead of exposing fresh metallic surfaces might allow access to more objects and could also be considered to gain sufficient information to answer a number of research questions. However, the plethora of different influences and processes during metal corrosion makes this task very challenging.

This session will therefore initiate the discussion on how to deal with alteration layers, from multiple perspectives and for all types of metal alloy, from copper and iron to silver, from the first metals to modern times. We want to explore matters such as the most efficient way to exploit the information potential of these outer surfaces, the best way to deal with difficulties arising from the combination of different analyses and to incorporate an environmental perspective on metal artefacts. Views from multiple disciplines, like archaeology, conservation science, materials science and technical art history will all aid in this discussion and widen our respective horizons.

We welcome all contributions dealing with the outer surface of archaeological metal objects as well as advantages and limitations in investigating them. The aim of this session is to raise awareness for this seemingly undervalued part of metal artefacts and to discuss how corrosion products can be incorporated into current archaeological research.

ABSTRACTS:

1

CORROSION ON METAL ARTIFACTS: RECENT DEVELOPMENTS AND CHALLENGES

**Abstract author(s):** Rose, Thomas (Ben-Gurion University of the Negev; Sapienza – University of Rome)

**Abstract format:** Oral

First and foremost, corrosion is the result of the interaction between a metal and its environment. Therefore, conservation sciences regularly examine corrosion products of archaeological objects in order to reconstruct the depositional environment and design the best treatment for the object. However, corrosion can also bear valuable information about the artifact and its context. Admittedly, it is often very challenging to get beyond the influences of the depositional environment. But should this not be our ambition in dealing with valuable heritage, allowing us to minimize invasive sampling because it can cause corrosion on the freshly exposed surface? Often, we have to deal with corrosion products anyway: they are the only thing remaining of what was once a metal object. Additionally, affordable and easy-to-use analytical methods become more and more popular and are usually providing surface analyses. Left aside these pure necessities, facing this challenge allows accessing valuable information otherwise ignored or even lost. Hence, picking up the challenge is definitely worth it, although it is not an easy one.

This presentation will provide an overview about the current developments and different challenges in the investigation of corrosion products in the archaeological disciplines. Based on this overview, the contributions in this session will be introduced and put in a wider context in order to provide a more general perspective on the plethora of aspects investigated through the analysis of corrosion products.

2

MULTIPLE-SCAN VOLTAMMETRY: AN ARCHAEOMETRIC TOOL FOR DATING ARCHAEOLOGICAL BRONZES

**Abstract author(s):** Mödlinger, Marianne (University of Genoa) - Doménech-Carbó, Antonio (Universitat de València) - Doménech-Carbó, María Teresa (Universitat Politècnica de València)

**Abstract format:** Oral

The application of a multiple-scan strategy to nanosamples taken from 18 cross-sections of Bronze Age arms and armour, as well as two Roman coins, using the voltammetry of immobilized microparticles (VIMP) methodology is presented. The described analytical method is non-invasive, as only a few nanograms of corrosion from the object's surface are needed for the analyses. The voltammetric responses in contact with aqueous acetate buffer can be attributed to the reduction of cuprite with variable degree of compaction and crystallinity revealing significant differences in the gradient of such properties with depth. The voltammetric study of the metallographic samples of the bronze objects shows correlation with the age of the objects, respectively the period of their deposition. We discuss also (potential) influence of different factors on the VIMP measurements, such as deposition context (soil, water), chemical composition of the copper alloys, and microstructural features (as-cast, annealed, work-hardened), and how to overcome these issues.

3

USING IRON CORROSION PRODUCT MULTI-TECHNIQUE ANALYSES TO TRACE THE TEMPERATURE OF ANCIENT FIRES: METHODOLOGY AND APPLICATION TO NOTRE-DAME IN PARIS

**Abstract author(s):** Neff, Delphine (CEA) - Dillmann, Philippe (CNRS) - Syvilay, Delphine - Azéma, Aurélia (LRMH) - L'Héritier, Maxime (Université Paris 8; CNRS-ArScAn)

**Abstract format:** Oral

Iron corrosion product layers formed on archaeological artefacts depend on their history. Forging, use and fires can induce corrosion in an atmospheric environment at ambient or higher temperatures. Then, the archaeological context environment induces further corrosion processes likely to evolve over time. High temperatures are among the factors much likely to change the nature of corrosion compounds. At low temperatures, in aerated media, goethite is the main precipitated corrosion product. Hematite can form from goethite at temperatures above 300°C. As fire temperatures usually exceeds 800 to 1000 °C, investigating the transformation of an artefact's ambient corrosion feature is likely to be used to trace the course of such an event.

To determine the corrosion phases and assess their evolution with temperature, a set of fifteenth-century corroded iron cramps from Metz cathedral were heated at 300, 400, 600, 800 and 1000°C during 1 and 6 hours. The resulting heated corrosion layers were analysed by SEM-EDS and μ-Raman spectroscopy on the surface and on cross sections. Furthermore, a temperature calibration curve was obtained from the decomposition of specific hematite spectrum peaks.

This methodology was then applied to iron cramps reinforcing the upper walls of cathedral Notre-Dame de Paris (early 13th c.) which suffered several hours of blaze. Corrosion product samples were collected in situ and transverse cross sections were prepared on a few deposited cramps. Elemental composition and structural analyses reveal the presence of a ten-micrometer-thick wüstite layer assessing temperatures higher than 570°C. Thanks to the calibration curve, temperatures between 600 to 1000°C were identified depending on the cramp location leading to a better understanding of the fire dynamics. Such study improves the knowledge of high temperature iron oxidation features. This method is likely to be applied on other archaeological sites to assess the importance (or existence) of past fires.

4 **INVESTIGATING TEXTILES IN METAL CORROSION PRODUCTS OF THE GALLOWAY HOARD, C. AD 700-900**

**Abstract author(s):** Harris, Susanna (University of Glasgow) - Davis, Mary (National Museums Scotland)

**Abstract format:** Oral

Textiles are some of the most ephemeral materials in the archaeological record. By examining the corrosion products of metals, textile researchers have been successful in detecting evidence for textiles (e.g. Bender Jørgensen 1992, Gleba 2017). Conservators encounter textile traces in corrosion products when working with metal artefacts. Textile are preserved in a spectrum of metal corrosion products ranging from predominantly organic material preserved due to the biocide effect of mineral salts, to fully mineral replaced structures (Janaway 1983). The effect of preservation in this way leads to unusual textile vestiges, as mineral preserved textiles adhere to metal structures creating patterns that can be difficult to identify, distinguish from metal dendrites, or the shape of corrosion itself. In this presentation, we discuss the practical and methodological issues of examining textile traces in metal corrosion products. Focusing predominantly on textiles preserved on the artefacts of the early medieval Galloway Hoard, we consider a suite of microscopy and digital imaging methods to identify textile structures. The methods covered include portable dino-lite microscopy, optical light microscopy, Scanning Electron Microscopy (SEM) and digital SLR using Reflectance Transformation Imaging (RTI). Through the results we consider the significance of the technical and contextual information gained from examining textile traces on the metal objects of the Galloway Hoard.

5 **THE ROLE OF IRON IN THE INTERPRETATION OF AN EARLY ANGLO-SAXON BURIAL SITE**

**Abstract author(s):** Penton, Sharon (Conservator in Private Practice)

**Abstract format:** Oral

Iron is probably the most common yet most neglected of the archaeological metals. It does not survive well underground but because of the way it reverts back into the soil it can preserve the impression of other organic materials around it in great detail. Cliffs End Farm is a prime example of how iron aided in the interpretation of an otherwise poorly preserved Anglo-Saxon burial site. A significant amount of information was extracted from the iron artefacts using investigative cleaning and analytical tools such as X-radiology, Scanning Electron Microscopy (SEM) and X-ray Florescence (XRF). X-radiography aided the careful micro excavation of artifacts from soil blocks and enhanced details of design and manufacture otherwise not visible. Mineral preserved organics such as cloth and plant materials could be identified with both visual examination as well as SEM. Other metal identified with XRF were preserved due to the preferential corrosion of the iron around it. Had these artifacts not been treated by a conservator detailed information leading to the interpretation of the site would have been lost.

6 **TO THE RAINBOW AND BEYOND: MULTICOLOURED CORROSION PRODUCTS ON SILVER AND GILT OBJECTS**

**Abstract author(s):** van der Stok, Janneke (University of Amsterdam; Metals Inc.) - Joosten, Ineke (Cultural Heritage Agency of the Netherlands) - Beentjes, Tonny - van Bommel, Maarten (University of Amsterdam)

**Abstract format:** Oral

Silver, gold and gilt copper and silver objects recovered from the sea may display an intriguing colour palette. What appears to be a dirty artefact at first glance, can unravel stories about life in the past. It all starts with realising that the outer surface of the object might contain valuable information. Information about its manufacture and use in the past, the object's degradation process, its chemical and mechanical stability and the relation with other finds from the same archaeological context.

The increasing awareness of the information potential of pristine and uncleaned archaeological objects results in an increased number of studies of the outer surface. These are often conducted with an array of analytical techniques, ranging from non-destructive (like X-ray imaging) to those that require destructive sampling (like metallography).

The Dutch AMOR-project is an example of such a study, where alteration layers play a key role. The main research question is: what would be the best way to extract information from precious metal objects from a marine context? More specifically, the outer layers of a selection of objects are meticulously examined to find traces that add to the artefact biography. A selection of analytical techniques is applied, based on visual examination of the differently coloured areas on multiple artefacts. By interpreting the results with an interdisciplinary team, effort is being made to transfer this knowledge from a purely academic exercise into practical output that appeals to the public. As this is quite a challenge, this presentation will elaborate on some of these issues, as well as on more technical difficulties that arose during the analytical studies. Overall, the added value of corrosion and its adhering material will be highlighted, based on (precious) metals finds from a marine context.

7 **METAL USE IN THE LATE ROMAN PERIOD. METHODOLOGICAL LIMITATIONS AND POSSIBILITIES OF PXRF DATA FROM COPPER ALLOYS FROM GERMANIA SECUNDA**

**Abstract author(s):** van der Meulen-van der Veen, Berber (Cardiff University)

**Abstract format:** Oral

As part of a larger PhD project into the material culture of the Late Roman period in Germania Secunda and Germania Magna, a large pXRF dataset of 651 Late Roman copper alloy dress accessories was gathered. The dataset consists of objects borrowed from a

variety of private collectors, museums and archives. This meant that the finds were not allowed to undergo deep-cleaning or destructive sample taking. As with all pXRF research on archaeological metals (e.g. Roxburgh 2019), this has raised issues about the influence of corrosion processes on the analysis results.

In this paper, I would first of all like to discuss the methodological intricacies of dealing with surface pXRF data from archaeological metals, both in running the analyses and the data processing stage afterwards. The methodological choices made for this project will be discussed, including data normalisation, proving internal consistency of results across the dataset and how to deal with over- and underrepresentation of certain elements (Fernandez et al. 2013).

Secondly, the aim is to formulate a more fluid approach to understanding metal use in the Late Roman period, by looking at the relative chemistry of these objects. This can address questions of access to raw materials, recycling practices and alloy choices both inside and outside the Roman Empire and across the 4th and 5th centuries. As the dataset includes both objects traditionally associated with the military and with female or "Germanic" identities, it can also be used to address a number of social questions. One of the methods explored in this context is the exploration of chemical spaces for copper (Bray et al. 2015) by tracing the presence/absence of arsenic, antimony, silver and nickel as trace elements in these copper alloys.

8 **MICROSCOPIC AND SPECTROSCOPIC DETERMINATIONS OF CORROSION PRODUCTS ON COINS AND OTHER METALLIC ARTEFACTS UNCOVERED BY METAL DETECTORS**

**Abstract author(s):** Gebremariam, Kidane (University of Stavanger)

**Abstract format:** Oral

Understanding of the corrosion products of archeological metal artifact is essential for well-informed conservation interventions. Preventive measures could also be taken to avoid or minimize deterioration of these objects during storage and display. Various methodologies can be applied for the characterization of the corrosion products on deteriorated metallic objects at different scales of observations depending on the focus of the study. Microscopic and spectroscopic methods are applied to explore the variations in the morphologies and compositions of corrosions products on some coins and different metallic objects acquired by metal detectors. Some of the results will be presented in this contribution. The corrosions products reflect the composition of the metal and its burial condition among other factors. Besides assisting conservation works, systematic study of the corrosion products of metallic objects could facilitate better understanding of the mechanisms of the deteriorations. It is also imperative to take into account the impact of the composition of the patina when applying non-destructive surface analytical methods such as X-ray fluorescence spectroscopy.

9 **CORRODED CLUSTERS: INVASIVE VERSUS NON-INVASIVE TECHNIQUES TO DETERMINE COPPER ALLOY ARTEFACT GROUPS FROM ALBALAT (ROMANGORDO, SPAIN)**

**Abstract author(s):** Peters, Manuel J.H. (Department of Applied Science and Technology, Politecnico di Torino; Department of History, Universidade de Évora; HERCULES Laboratory, Universidade de Évora) - Bottaini, Carlo (HERCULES Laboratory, Universidade de Évora; CityUMacau Chair in Sustainable Heritage, Universidade de Évora) - Gilotte, Sophie (Centre National de la Recherche Scientifique) - Mirão, José (HERCULES Laboratory, Universidade de Évora; Department of Geosciences, Universidade de Évora) - Grassini, Sabrina - Angelini, Emma (Department of Applied Science and Technology, Politecnico di Torino)

**Abstract format:** Oral

In archaeometry, the move to non-destructive methods has led to widespread criticism concerning the use of portable X-ray Fluorescence (pXRF) for the investigation of archaeological artefacts. Corroded artefacts can provide unreliable results when it comes to surface analysis, due to enrichment and depletion processes such as decuprification and stannification.

This research investigates artefacts from the Islamic site of Albalat (Southwest Spain), which was occupied from the 10th to the 12th century AD. For this study, more than 30 previously unexplored copper-based objects were selected. Several pXRF measurements were carried out on the surface of each artefact, as well as on the metal cross-sections. The results were submitted to statistical analyses including principal component analysis (PCA) and cluster analysis to find compositional trends and possible correlations between clusters and artefact types.

Although there are differences in the individual compositional results of each artefact, related to the corrosion process, the identified clusters for both methods are very similar. The two largest clusters are a group of relatively pure copper-based alloys and a group with a significantly higher Zn component. Other elements include lead and tin. The clusters appear to correspond to clear artefact categories. The copper artefacts are primarily of simple form and function, representing implements such as nails. The brass-like alloys appear to be used for decorative elements.

The correlation between alloy and artefact class implies a conscious selection of alloy components for the desired function of the artefact. This provides an insight into Islamic metal manufacturing techniques in the Iberian Peninsula in the 12th century AD.

On the one hand, this study highlights some of the common issues with surface analysis. On the other hand, it shows that, when treated carefully, non-destructive analysis can be used in a comparative way, yielding similar results to destructive analysis on the same samples.

A. ORGANIC PSEUDOMORPHS: AN INTRODUCTORY GUIDE FOR CULTURAL HERITAGE PROFESSIONALS

**Abstract author(s):** Acuna, Katerina (Winterthur/University of Delaware Program in Art Conservation)

**Abstract format:** Poster

Organic pseudomorphs are mineralized organic materials preserved in the corrosion crusts of metal artifacts. They can reveal information about organic materials in contact with metals that have long since degraded, like wood and textiles. Pseudomorphs tend to form in stagnant, damp environments where metal objects and organic materials are adjacent and are buried in soil conducive to slow fiber degradation and metal corrosion. The surfaces of pseudomorphs are delicate and vulnerable to physical damage. It is important that archaeologists and cultural heritage professionals are widely aware of pseudomorphs so they can be documented, physically preserved, and studied with greater frequency. This poster will provide basic guidelines on what pseudomorphs are, how to identify them, how to care for them onsite, and offsite follow-up. The poster will be accompanied by an educational pamphlet for conference participants to share with students and colleagues. The guidelines on the poster and pamphlet will be informed by an ongoing research project between the Winterthur/University of Delaware Program in Art Conservation and the University of Pennsylvania Museum of Archaeology and Anthropology (the Penn Museum), in which digital microscopy has been used to document pseudomorphs from Ur. Images of pseudomorphs from Ur obtained during research carried out in the spring of 2020 will accompany the guidelines as didactic tools.

B. ANALYSIS OF UNCONSERVED ARCHAEOLOGICAL COPPER ALLOY OBJECTS

**Abstract author(s):** Vasiliauskaite, Asta (Klaipeda University; Vytautas the Great war museum)

**Abstract format:** Poster

This poster will present an assessment of the applicability of the pXRF Niton XL3t to non-destructive analyses of archaeological metal with focus on the analysis of the composition of copper alloys and the effects of corrosion. Would it be any use to perform analytical analysis before conservation? The objects from two burials dating 3rd-5th centuries AD from Marvele cemetery in Kaunas, Lithuania were selected for XRF analysis. Marvele cemetery dating 2nd to 14th centuries AD is one of the largest burial sites in Lithuania with about 1500 human burials and few hundred horse burials. Few iron and over 30 copper alloy objects from the rich woman's burial and the child's burial underneath it were selected for metal composition analysis. Two readings were taken for each object: one at untreated area, covered with thick layers of corrosion products, and another at the cleaned spot. Results are discussed in relation to the composition similarities of the objects from both burials and the data usefulness for conservators to inform them of the degree to which the corrosion crust is developed.

319 IMPR - PHYTOLITHS IN GEOARCHAEOLOGY AND MICROMORPHOLOGY

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Vrydaghs, Luc (MARI - VUB) - Polo-Diaz, Ana (Marie Skłodowska-Curie Fellow - MSCA-IF, Department of Archaeology, University of Sheffield)

**Format:** Regular session

Phytolith studies are an essential aspect of modern geoarchaeological research. Phytoliths are indeed observed on samples provening from diverse geographical locations, environments and time periods. Present session intends to bring together geoarchaeologists/micromorphologists and phytolith specialists working on archaeological deposits.

Traditionally, both specialists work on different mediums: the phytolith specialist analyses bulk samples, while the geoarchaeologist/micromorphologist studies thin sections of sediment/soil blocks preserving the original stratigraphy of the deposits. Consequently, both approaches document different aspects of the phytolith record. Thin sections inform about the spatial context and formative processes. The analysis of bulk samples details the morphological diversity of the assemblages and relative concentrations. Integrating both methods has thus potential to considerably boost their respective analytical capacities and to fuel discussion in both research fields. Of major relevance are issues relating to morphological diversity, the (post)depositional histories and the discrimination of phytoliths sharing (or not) a common botanical origin.

One is forced to note that indeed few phytolith specialists attend micromorphological workshops. Likewise few micromorphologists attend IMPR. The purpose of present session is to initiate such meetings aiming at bridging both research fields. As a first step, micromorphologists are invited to report on their phytolith observations regarding the questions above highlighted, and to discuss them with the broader phytolith community.

A microscopic session will follow these presentations. Its purpose is to raise awareness among specialists of both fields on the potential of phytolith analysis of thin sections.

ABSTRACTS:

1 20 YEARS OF LOOKING AT PHYTOLITHS IN ARCHAEOLOGICAL SOIL THIN SECTIONS: A REFLEXION

**Abstract author(s):** Devos, Yannick (Vrije Universiteit Brussel)

**Abstract format:** Oral

Traditionally, phytolith research focusses on the study of bulk samples collected during archaeological field campaigns. However, phytoliths are regularly reported by soil micromorphologists studying their archaeological soil and sediment thin sections. These thin sections are thin slices of undisturbed soil and sediments. Importantly, all components are captured in the position they had in the original soil and sediment profiles. Despite a series of limitations – the phytolith record is not concentrated, phytoliths cannot be rotated and are cut at random angles – the study of phytoliths in these thin sections is feasible. Beyond being a feasible task, it is also a promising asset (Vrydaghs & Devos, 2018).

Over the last 20 years a specific research protocol has been developed to describe and interpret the phytoliths observed in thin sections. Present contribution intends to discuss to what extent this method can contribute to our understanding of different aspects, such as the origin and taphonomical history of plant remains in archaeological deposits. Furthermore, it will be argued how it opens perspectives for morphometrical analysis and how it can be integrated within the framework of geoarchaeological research.

The presentation will be illustrated with a series of case studies, mainly from Brussels and Flanders.

2 PHYTOLITHS IN EARLY MEDIEVAL FLOORS FROM NORTHERN FRANCE

**Abstract author(s):** Borderie, Quentin (CNRS UMR7041 ArScAn)

**Abstract format:** Oral

Due to the lack of well-preserved stratifications and to the absence of micromorphological investigation on historical domestic building, the nature of medieval indoor floors is barely known in Western Europe, except concerning hardened stone materials (pavement, mosaics). Recent micromorphological investigations focused on early medieval floors from high statute dwellings (castra) from Gien (Loiret) and Boves (Somme) have revealed that floors can be partly or totally made with graminæ phytoliths. Those plant remains are located on the surface of earthen floors, but they can also be the only material recovering trampled waste. The absence of phosphate features or of faecal spheruliths ruled out the hypothesis of the use of dung to build the floors. Moreover, the morphometric analysis of the dendritic phytoliths show that most of them are formed in cereal husks. Rare occurrence of such a practice have already been notice in France, but only for the 14th – 15th c., like in the milites houses of Chalucet (Haute-Vienne). In Boves, the thickness of the layers and the probable regular cleaning of floors seem to indicate that the processing of crops took place into the building. In Gien, the plant mats are thinner and include other plant material. This can indicate that the crops are processed in the surrounding and that husks are reuse in order to build floors. In addition to the new data on floor material and building processes, those results also highlight the ways of processing cereal and give new evidence of social practice of waste management.

3 ANIMAL INDOOR PENNING AND STORAGE ACTIVITY IN THE EASTERN PYRENEES: THE CASE-STUDY OF LATE IRON AGE BALTARGA, Cerdanya

**Abstract author(s):** Portillo, Marta (Department of Archaeology and Anthropology, Institució Milà i Fontanals - IMF, Spanish National Research Council - CSIC, Barcelona) - Sisa, Joaquim (Department of Prehistory, Autonomous University of Barcelona - UAB) - Alliot, Pascal - Olesti, Oriol (Department of Antiquity and Middle Age Studies, Autonomous University of Barcelona - UAB)

**Abstract format:** Oral

Over the last decades microarchaeological and ethnoarchaeological approaches including combined studies of phytoliths, calcitic faecal microfossils and micromorphology have demonstrated the critical importance of animal dung deposits for reconstructing past human life-ways in mountain areas, primarily within naturally sheltered sites such as caves and rockshelters. The case study of Baltarga (Bellver de Cerdanya, eastern Pyrenees) provides direct evidence from simultaneous storage and animal penning, along with the faunal remains, in situ in anatomical connection, of a number of ovicaprines and even a horse, occurring within the same building, corresponding to a destruction event by fire dating to the second half of the 3rd century BC. Through simultaneous examination in micromorphological thin-section and integrated phytolith and calcitic dung spherulite analyses, the current study provides direct evidence for animal management and organisation of space at Late Iron Age Baltarga by examining indoor animal penning deposits at high-resolution.

Micromorphological results point to a well-preserved microstratigraphic sequence that allows us to characterize this type of occupation deposits related to animal management through highly significant markers and to reconstruct its use/life episodes at an optimal resolution scale. Phytolith-rich assemblages from in situ dung accumulations further provide insights into herbivorous regimes, dominated by a range of grass matter suggested to derive from fodder and/or grazing through the penning lifetime.

This integrated approach contributes to the understanding of the depositional pathways and taphonomic histories of penning deposits within built environments, critical for the reconstruction of activity areas and practices related to animal management

strategies, foddering/grazing activity, and their archaeological implications for site formation processes, concepts of space within the settlement, health, as well as the complexity of interactions between people and animals in mountain areas.

4 **PHYTOLITHS AND CAVE AND ROCK-SHELTER DEPOSITS IN EARLY FARMING: PROVIDING ARCHAEOLOGICAL CONTEXT FROM THIN SECTIONS FOR MICROMORPHOLOGICAL ANALYSIS**

**Abstract author(s):** Polo-Diaz, Ana (Department of Archaeology. University of Sheffield.)  
**Abstract format:** Oral

Mountainous areas can be considered a major vector in the introduction and expansion of early farming in SW Europe. Such relevance is closely related to current evidence indicating an extensive use of caves and rock-shelters to keep livestock from the Neolithic through to the Bronze Age. Accordingly, deposits preserved in these sites frequently consist of fumier accumulations from animal herding, but they also hold evidence of further aspects of early farming life as living areas and burial features. The resulting sediments of these activities are a mixture of weathered and burnt organic remains in which a significant portion corresponds to phytoliths. In parallel to traditional quantitative study of phytoliths from bulk samples, analysis of phytoliths using sediment and soil micromorphology can improve our understanding of the dynamics involved in the formation process of the deposits.

In this presentation a selection of phytolith assemblages documented in thin sections for micromorphological analysis from cave and rock-shelter deposits from the Iberian Peninsula is presented. The objective is to emphasize the importance of addressing the study of phytoliths in light of the sedimentary context of preservation for the characterization of early agro-pastoral activities and the assessment of the integrity of the archaeological record.

5 **PHYTOLITH AND MICROMORPHOLOGICAL ANALYSIS AT THE MIDDLE-TO-LATER STONE AGE SITE OF LOVEDALE, FREE STATE, SOUTH AFRICA**

**Abstract author(s):** Wroth, Kristen (Eberhard-Karls-Universität Tübingen) - Bousman, Britt (Texas State University) - Tribolo, Chantal (CNRS-Université Bordeaux Montaigne) - Rossouw, Lloyd (National Museum, Bloemfontein) - Kolska Horwitz, Liora (Hebrew University of Jerusalem) - Miller, Chris (Eberhard-Karls-Universität Tübingen) - Toffolo, Michael (CNRS-Université Bordeaux Montaigne)  
**Abstract format:** Oral

The archaeological record of South Africa has provided striking evidence for behavioral variability and technological innovation among groups of early modern humans. Much of our understanding of these groups comes from the deep, well-stratified deposits found within caves and rock shelters, shedding light on many aspects of past behaviors. However, caves and sheltered sites are not available in all landscapes and this record may produce a biased view of important human activities, such as hunting and foraging behaviors that took place in the open landscape. Open-air sites are often more difficult to find and interpret due to a variety of concerns over preservation and their placement within a dynamic, erosional landscape. Thus, the combination of geoarchaeological and microarchaeological techniques is key to understanding how open-air sites formed, how they changed through time, and their place within specific environmental and ecological conditions.

This paper presents the results of micromorphological and phytolith analysis on sediment samples collected from Lovedale, a Middle-to-Later Stone Age site located in the Free State near Bloemfontein. The micromorphological analysis of intact blocks of sediment from this open-air site provides insight into the site formation processes, showing shifts in the depositional environment as the course of the local river changed. The micromorphology also gives important context for interpreting the surprisingly rich phytolith samples. Grass phytoliths dominate the plant microremain assemblage and show evidence for vacillations between wetter and drier periods throughout MIS 4-2. Together, these analyses provide a more holistic picture of the paleoenvironment, speaking both to local landscape change and regional environmental shifts. These data address some of the gaps in the paleoenvironmental and geoarchaeological record for this period in the region and add to a growing picture of human-environment interactions during a critical stage of evolution.

6 **FIRES OF A HOUSE – BURNING EVENTS IN A MIDDLE BRONZE AGE VATYA HOUSE AT SZÁZHALOMBATTA-FÖLDVÁR TELL SITE (HUNGARY)**

**Abstract author(s):** Peto, Ákos (Hungarian University of Agricultural and Life Sciences) - Kovács, Gabriella - Vicze, Magdolna (independent researcher)  
**Abstract format:** Oral

The investigation of fires and burning has a long history and the applied methods are also greatly varied. There are a number of investigations regarding the Neolithic, but Bronze Age has not been excessively studied in this regard so far. In this study we aim to add further details to this topic via the conjoint application of thin section soil micromorphology and phytolith analysis. The combination of these techniques has been proven to be highly advantageous due to their high resolution. Various burning events were investigated at a Middle Bronze Age Vatyá house from the tell site of Százhalombatta-Földvár, Hungary. Three types of fire are in focus here out of which two are thoughtfully prepared and implemented. One of them was set for the cleaning of the house, the other one for the hearth, while the last one closed down the house's life. While in the first two cases everyday life is under the microscope, the latter is more enigmatic and it is hard to tell if it was an accident or purposeful destruction. Thin section soil micromorphology and phytolith analysis in fixed analytical environment (thin section) was applied to shed light on the details of the fire events.

7 **INTEGRATING PHYTOLITH AND MICROMORPHOLOGICAL RESEARCH IN CENTRAL ANATOLIA: INSIGHTS INTO EARLY HOLOCENE HUMAN-PLANT-ANIMAL DYNAMICS**

**Abstract author(s):** Garcia-Suarez, Aroa (University of Reading) - Portillo, Marta (Institució Milà i Fontanals - Spanish National Research Council)  
**Abstract format:** Oral

The tight integration of phytolith and micromorphological methodologies is a very promising line of work in environmental archaeology, since it allows us to combine the strengths of both quantitative (i.e. concentrations of micro-remains) and qualitative (i.e. micro-contextual) studies. In this paper, we present case studies from the Central Anatolian Neolithic record to illustrate the many advantages associated with this interdisciplinary approach, particularly when capable of expanding/dismissing functional interpretations of archaeological contexts defined by field observations. We then evaluate these results under the light of ethnographic research in modern Turkish villages, highlighting how these investigations contribute to refining archaeological interpretations of deposits and embedded micro-remains from comparable contexts.

Phytolith spot samples were collected from the sediment blocks before preparation for manufacture into thin-sections, resulting in the strong association of microfossil and micromorphological data. Results demonstrate how the combination of geo- and bio-markers leads to solid interpretations on key archaeological issues such as uses and concepts of space, landscape exploitation and herd management, in particular feeding regimes and dung use. Specifically, micromorphology has made significant contributions to our understanding of the depositional pathways and taphonomic alterations of plant contents in the studied contexts, whereas phytolith analyses of spot samples have allowed us to overcome the limitations posed by the observation of plant microfossils in micromorphological thin-sections. Through this combination, depositional processes, ecological choices and post-depositional alterations are identified and understood more accurately.

8 **ONCE UPON A TIME... STORYTELLING PHYTOLITHS IN ARCHAEOLOGICAL THIN SECTIONS FROM THE ROYAL TOMB OF QATNA (SYRIA)**

**Abstract author(s):** Pümpin, Christine (Integrative Prehistory and Archeological Science - IPAS, University of Basel) - Vrydaghs, Luc (Maritime Cultures Research Institute - MARI - Vrije Universiteit Brussel) - Reifarth, Nicole (CICS - Cologne Institute of Conservation. Sciences Textiles and Archaeological Fibres - TAF) - Doutrelepon, Hugues (ROOTS, Bruxelles) - Ball, Terry (Department of Ancient Scripture, Brigham Young University - Provo)  
**Abstract format:** Oral

The discovery in 2002 of the Late Bronze Age Royal Tomb of Qatna (Tell Mishrife, Syria) – in use for about 450 years – implied the integration of many different disciplines to collect and save as much data from the archaeological find as possible. The examination of soil thin sections from the different burial chambers and passageways provided evidence for various phases of construction as well as other human activities in the tomb. During this study, phytoliths have been repeatedly observed. For a better understanding of their origin and nature, the biogenic opal in the thin sections from organic floor deposits, vessel contents, as well as deposits directly connected with human burials were analysed. In general, phytoliths are present in most parts of the tomb. However, there are areas where they are conspicuously frequent and in some cases still in anatomical position, such as on a stone bench, in-between a multi-layered textile deposit mineralised into gypsum, associated with a burial. These biogenic remains most likely came into the tomb in conjunction with the construction material and the grave goods. With the systematic and careful documentation including detailed mapping, the study of phytoliths in thin sections proved to be of special significance, as it provided important information about preservation conditions, sediment accumulations or even details of funeral activities. The results demonstrate the importance of a close cooperation between micromorphology and phytolith studies, permitting new perspectives understanding micro-remains through closely intertwined analytical methods in complex archaeological structures.

9 **PHYTOLITH AND MICROMORPHOLOGY RESULTS FROM A NEOLITHIC ASH-PIT IN EASTERN CHINA**

**Abstract author(s):** Duan, Qimeng (Institute of Cultural Heritage, Shandong University) - Rao, Zongyue (Shandong Provincial Institute of Cultural Relics and Archaeology) - Jin, Guiyun (Institute of Cultural Heritage, Shandong University)  
**Abstract format:** Oral

Dongjiabai site locates in eastern China, in which Neolithic remains including houses and ash pits dated to 6500-6000 BP had been unearthed. In this research, soil micromorphology and phytolith samples were collected from ash pit H18 in which 13 deposit layers were recorded as ①-⑬. High density of phytolith from rice and millets were extracted from layer ③, ④, ⑩a, ⑩c, and ⑪. Soil micromorphology analysis shows that the high density of crop phytoliths in some layers were the results of the deposition of burnt organic materials including crop-processing by-products other than fresh by-products.

In our previous research, the high density of crop phytoliths, especially that from cereal husk, were used as a proxy to infer the location of crop processing. However, by combining the analysis of phytolith and soil micromorphology in this research, we conclude that the previous proxy is not appropriate. This research indicates that when discussing crop processing issues, the phytolith analysis should be done along with soil micromorphology to define the formation process.

INTEGRATING PHYTOLITH ANALYSIS OF BULK SAMPLES AND SOIL THIN SECTIONS. THE CASE OF THE RUE DES BOÎTEUX, BRUSSELS (BELGIUM)

**Abstract author(s):** Hermans, Rosalie (Maritime Cultures Research Institute - MARI, Vrije Universiteit Brussel - VUB) - Chevalier, Alexandre (Royal Belgian Institute of Natural Sciences - RBINS, Brussels) - Albert, Rosa Maria (Catalan Institution for Research and Advanced Studies - ICREA; Dep. of History and Archaeology, University of Barcelona) - Devos, Yannick - Vrydaghs, Luc (Maritime Cultures Research Institute - MARI, Vrije Universiteit Brussel - VUB)

**Abstract format:** Oral

During a rescue excavation in 2014, a Dark Earth (13th – 15th centuries) was uncovered at Rue des Boîteux, Brussels (Belgium). An interdisciplinary study, which included geoarchaeology and archaeobotany, permitted to identify this Dark Earth as corresponding to the remains of a late medieval garden.

The present contribution focuses on the results obtained from the phytolith analysis from the Dark Earth. The phytolith analysis was conducted within a complex methodological framework. It involved the analysis of phytoliths from bulk samples processed through three different extraction methods and the study of soil thin sections. Despite its potential, the study of phytoliths from soil thin sections is not commonly applied. The combination of both methods is even less frequent (e.g. Banerjea et al., 2019).

Within this presentation, we aim to evaluate the advantages and disadvantages of combining various phytolith extraction methods from bulk samples. In a next step, the results of the analysis of bulk samples are compared with those obtained from the analysis of soil thin sections. These comparisons show that the different methods complement each other. This integrated approach permits to obtain a more detailed dataset regarding morphological diversity and relative frequencies. It also enables a better understanding of the origin of the phytoliths and the impact of (post)-depositional processes on them.

CONTEMPORARY APPROACHES TO THE INVESTIGATION AND MANAGEMENT OF ARCHAEOLOGICAL RESOURCES IN ALLUVIAL ENVIRONMENTS

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Crabb, Nicholas - Carey, Chris (University of Brighton) - Howard, Andy (Landscape Research and Managment) - Ghilardi, Matthieu (Centre Européen de Recherche et d’Enseignement des Géosciences de l’Environnement - CEREGE)

**Format:** Regular session

Alluvial environments contain rich archaeological records, both in terms of ecofactual and artefactual evidence, but they are also challenging to investigate. The subsurface stratigraphy of river valley floors is complex, with fine-grained alluvial sediments concealing archaeological remains and sites, whilst at the same time preserving organic deposits. The burial of such rich archaeological records within and under alluvium renders most conventional techniques of archaeological prospection ineffective and alternative solutions, largely derived from earth sciences, have therefore been sought.

Although recognition of this challenge is not new, the variety and sophistication of methods available has increased in recent decades. This includes, but is not limited to, terrestrial investigations to create stratigraphic profiles of sediment architectures, airborne and satellite remote sensing techniques to understand the geomorphological complexity of these systems, and deeper methods of geophysical survey, allied to 3-dimensional computational modelling. In tandem with this, absolute dating of sediments has provided a step-change in understanding the timing and speed of change within these sedimentary systems. This is most commonly achieved through radiocarbon and optically stimulated luminescence calibrated through Bayesian statistics, and has led to the definition of legacy sediments and wider-scale human impacts across catchments. Despite this, optimal methods for the investigation of archaeological potential within these alluvial systems requires further development. Consideration of how these different data sources and approaches can be integrated will provide greater understanding of past human impacts across river catchments and ultimately enable more effective management of the historic environment resource.

In this session, we therefore call for papers from archaeologists and associated heritage professionals that critically assess the role that multi-methodological approaches can make towards elucidating the alluvial archaeological record. In particular, we welcome contributions that integrate these methods synergistically to form more holistic interpretations and models of alluvial evolution and past human-environmental dynamics.

ABSTRACTS:

1

ALLUVIAL FLOODS IN THE GREEK-ROMAN SETTLEMENT OF ELEA-VELIA: AN ARCHAEOLOGICAL PRELIMINARY REPORT

**Abstract author(s):** Tescione, Teresa - Cicala, Luigi (Università di Napoli Federico II)

**Abstract format:** Oral

The Elea-Velia settlement is located in the Southern Cilento. The town has been founded in the end of the 6th century BC by Phoecea inhabitants. The entire history of the Greek-Roman town has been influenced by the Frittolo stream dynamics which caused several alluvial floods in the Southern Quarter since the 1st century AD until the 6th century AD, when the Greek-Roman settlement has been definitely abandoned.

The recent geo-archaeological investigations have identified the cause of the alluvial floods in the human-environmental interaction and they have carried out a paleo-environmental reconstruction.

The paper involves a multi-methodological approach, combining the results of geological, environmental and archaeological studies. The main goal is to present a chronological reconstruction of the settlement changes following each alluvial flood event and the management/acceptance of the hydraulic risk affecting the area. For this purpose, the aim of the paper intends to show available data from a sample-area of the recent archaeological excavations in the Southern Quarter. Specifically, the results of the pottery’s chrono-typological and quantitative analysis and walls’ stratigraphical studies are integrated to obtain a wider reconstruction.

2

GEOMORPHOLOGICAL AND ARCHAEOLOGICAL PERSPECTIVES REVEAL THE IMPACT OF ALLUVIAL ENVIRONMENTS ON HUMAN ACTIVITIES IN THE PERGAMON MICRO-REGION—AND VICE VERSA

**Abstract author(s):** Becker, Fabian (Freie Universität Berlin / Physical Geography) - Knitter, Daniel (Christian-Albrechts-Universität zu Kiel / Landscape Ecology and Geoinformation) - Yang, Xun - Schütt, Brigitta (Freie Universität Berlin / Physical Geography)

**Abstract format:** Oral

Alluvial settings play a key role in the understanding of site locations in the micro-region of the Hellenistic–Roman Imperial urban centre of Pergamon—not only for the growth of the city on an alluvial fan, but also for the rural estates, agricultural areas, and the road network in the wide Bakırçay alluvial plain.

We integrated different types of data related to a range of spatial entities and temporal scales to parse the entangled development of the alluvial environments around Pergamon and in its hinterland.

This multi-method approach aims to reconstruct the distribution of (pre-)recent wetlands and flood dynamics. It is based on the analysis of the structural setting of a graben-conducted plain inherited from Miocene fault-block tectonics, palaeo-environmental data from sediment sequences, historic maps of the early excavators, geomorphometric data, and multi-spectral satellite imagery. We used least-cost path analysis to integrate the different approaches and to evaluate the effects of different alluvial settings on settlements and human movement. Furthermore, a geomorphological contextualisation of archaeological data from the urban centre of Pergamon and its micro-region supports the palaeo-environmental reconstructions.

Our analyses conducted in the Bakırçay plain reveal that the ancient road network around Pergamon was quite well adapted to the dynamics of the alluvial plain, e.g. flooding and seasonal wetlands. Sedimentology and tectonics show that the general setting of the plain in ancient times and today was similar; although parts of the plain are flooded in winter, the development of settlements and the road network was possible.

The analyses of the Bergama alluvial fan showed that humans actively shaped the hydro-morphological setting of (peri-)urban areas—including construction terraces and river embankments. Moreover, humans have also been affected by increased morphodynamics, such as flooding and sediment dynamics.

3

REMOTE SENSING IN ALLUVIATED LANDSCAPES: THE POTENTIAL OF A SYNERGISTIC APPROACH TO ENVIRONMENTAL MODELLING OF THE RIVER VALLEY FLOOR

**Abstract author(s):** Crabb, Nicholas - Carey, Chris (University of Brighton) - Howard, Andy (Landscape Research and Managment) - Jackson, Robin (Worcestershire Archaeology) - Brolly, Matthew - Burnside, Niall (University of Brighton)

**Abstract format:** Oral

The deposition of fine-grained alluvial sediments within river floodplains can bury, conceal, and preserve archaeological sites and features. These sediments are often thick (>1m), preventing the detection of archaeological remains using common prospection techniques, such as shallow geophysical survey and aerial photography. Despite this, it is possible to determine zones of archaeological/paleoenvironmental potential in alluvial environments through deposit modelling; the recording of sub-surface sediments and stratigraphy, to identify geomorphological variation. This is normally achieved through intrusive investigations, such as boreholes/coring or trial trenching. However, the analysis of alluvial landform assemblages from remotely sensed data has significant potential to aid the investigation of these environments. Moreover, with several recent technological advancements, such as the advent of small Unmanned Aerial System (sUAS) instruments and increasing spaceborne capabilities, remotely sensed datasets are increasingly accessible for geoarchaeological research.

This paper provides an assessment of the capability of contemporary remote sensing techniques (e.g. airborne LiDAR, Synthetic Aperture Radar (SAR), and satellite and sUAS mounted multi/hyperspectral) to model geomorphological components of river valleys and identify their archaeological potential. It reviews previous applications and provides a case study from the Lower Lugg valley, UK, where these datasets are compared with ground-based sediment sampling. This research examines the relationship of near-surface and sub-surface sediment variability of different valley components through computational image analyses. It also uses separability measures to provide a quantification of the effectiveness of different image enhancement procedures for the characterisation of these components. The results demonstrate these technologies can provide significant insights into the geomorphological complexity and variability of alluvial environments and subsequently facilitate a geoarchaeological assessment of their potential. The results will, therefore, be of interest to archaeologists and heritage managers working within these environments, as they have the potential to offer a more cost-effective and detailed representation of archaeological resources in alluviated landscapes.

**APOGEE, DECAY AND TRANSFORMATION: A GEOARCHAEOLOGICAL PERSPECTIVE ON ABANDONMENT AND POST-ABANDONMENT PROCESSES IN THE TEMENOS OF THE ARTEMISION OF EPHEBUS**

**Abstract author(s):** Lourenço Gonçalves, Pedro (ÖAI - ÖAW)

**Abstract format:** Oral

Transformation processes on the Artemision of Ephesus following its heydays (i.e., during the Roman Imperial era and the phases postdating the end of the cult until Mediaeval times) are the target of ongoing geoarchaeological investigations as part of the multidisciplinary research project “ART\_TE – Temenos&Territorium” (ÖAI / ÖAW). Since the rediscovery of the temple 125 years ago, research has targeted the consecutive temple buildings and associated altars, largely disregarding the post-Roman deposits and remains. The focus of the ART\_TE project is not the direct impact of a divinity, nor sacred buildings and votive deposits, but rather the infrastructural facilities, the temenos, and the economic and political power and significance of the sanctuary, during Roman times and beyond the closure and abandonment of the temple. Planned geoarchaeological investigations during 2020 included the drilling of boreholes in the area of the temenos with subsequent sedimentological and geochemical analyses of collected samples. However, fieldwork was postponed in 2020 due to the COVID-19 pandemic, and it is still uncertain when this work will be able to resume. More than presenting the context of our project and the preliminary results of the on-going investigations, this paper aims to discuss alternative strategies and methods for geoarchaeological research, particularly when fieldwork and the acquisition of sedimentological data is not guaranteed.

**GEOARCHAEOLOGY OF THE MEDIEVAL BRIDGE AT AVIGNON (SOUTH FRANCE): MANAGING AND IMAGING THE GEOSCIENCES, ARCHAEOLOGICAL AND HISTORICAL DATA**

**Abstract author(s):** Ghilardi, Matthieu (CEREGE - CNRS)

**Abstract format:** Oral

This paper aims to precisely locate the medieval arches of the so called Avignon’s (Saint Bénézet) Bridge (South France) and to reconstruct the fluvial dynamics of the Rhone River from Early Medieval Times to the 18th century AD. Until now, just four remnant arches are still visible and it is estimated that 22 arches (which represents a total length of approximately 920 meters) were built to span over one of the largest French Rivers. A medieval wooden bridge was probably erected from 1177 until 1185, and was rebuilt with stone arches around mid-13th Century AD. The structure of the bridge being vulnerable, seasonal floods proved a neverending threat and cause of damage which was frequently repaired with masonry or wood. Questions arose about the location of the “lost arches” and evident flood. From 2011 to 2014, a joint team composed by laboratories affiliated to the French Public Research Centre (CNRS) and to Universities of Avignon and of Aix-Marseille aimed to link the different phases of constructions/destructions of the monument with the fluvial dynamics of the Rhone River for the concerned period. The geoarchaeological approach adopted comprised bathymetric surveys together with geophysical prospections in order to reveal potential locations of arches within the modern Rhone River channels and on the Barthelasse fluvial island. Finally, boreholes have been drilled and later linked with the geophysical data, to reveal the alluvial litho-stratigraphy and describe the geomorphic the changes in the fluvial system. Stratigraphic evidence was reconstructed with geophysical surveys, optically stimulated luminescence and radiocarbon chronologies. Finally, a 4D visualization has been constructed that helps to better understand the relationships between the bridge and the Rhone River during its period of use.

**HISTORY OF FLOODS. ANALYSIS OF CERAMIC ASSEMBLAGES FROM THE PISA SAN ROSSORE’S ANCIENT SHIPS**

**Abstract author(s):** Tescione, Teresa (Università di Napoli Federico II) - Pace, Gloriana (Museo delle Navi Antiche di Pisa) - Camilli, Andrea (Soprintendenza Archeologia Belle Arti e Paesaggio per le province di Pisa e Livorno)

**Abstract format:** Oral

The paper’s aim concerns the chronological reconstruction of some flood events through the analysis of ceramic assemblages. This research intends to propose an analysis model of archaeological records deriving from natural catastrophic phenomena.

The case-study is the archaeological site of Cantiere delle Navi Antiche in Pisa San Rossore. The excavation has revealed that in a watercourse, probably a tributary of the river Auser, almost eighteen ships, were embedded under eight centuries of silt and clay (3rd cent. BC – 5th cent. AD).

After some exceptional floods due to intense rain, the Arno river broke its embankments close to a bend and poured out huge quantities of water and sediments in the area of this canal, sweeping away everything and leaving materials in the hollows of the ground.

The paper focuses in the analysis of the stratigraphic sequences in the north and south-west area of San Rossore basin (Area 5 and Ampliamento Sud Area), characterized by almost five main catastrophic floods, since Republican age (3rd – 1st cent. BC) until the Late Roman time, in which some riverboats with cargo still on board were involved.

The repeated alluvial floods and the movement of the water stream changed the pottery’s primary contexts. Although, the set of ceramic materials offers a wide range of case studies of ‘input’ in the stratifications, with objects accidentally fallen into the water or thrown purposely, those belonging to the equipment on board or loading ships, those conveyed by floods, etc.

The chrono-typological and quantitative analysis of pottery assemblages revealed a residuality rates and, at the same time, it was useful to date the archaeological deposit. The information processing depends on data recording in a geographical database which allowed the spatial intra-site distribution of pottery in the alluvial deposits.

**SHALLOW WATER 3D SEISMIC ATTRIBUTE ANALYSIS OF MEDIEVAL ARCHAEOLOGICAL FEATURES IN SOUTHERN SCHLESWIG, GERMANY**

**Abstract author(s):** Detjens, Stine (Centre for Baltic and Scandinavian Archaeology - ZBSA) - Gross, Felix - Wilken, Dennis (Christian-Albrechts-Universität zu Kiel)

**Abstract format:** Poster

Archaeological assets in the Baltic Sea region are often found at the land-water-transition. Since excavations are time- and cost-intensive and require extensive drainage, geophysical methods like marine 3D seismics are attractive alternatives.

For archaeological prospection image quality is key. Studies do not only aim at detecting objects present, but at characterising them and gaining knowledge about them. This includes size, shape, depth and other properties, e.g. the degradation status.

Seismic attributes (SA) are powerful analysis methods designed to extract information from seismic reflection data that may be more subtle in a traditional seismic image. Being sensitive either directly to changes in seismic impedance, layer thickness or seismic textures and morphology, they enable enhanced quantitative and qualitative interpretation of 3D data sets. Using SA in archaeology has never been tested before and is yet a logical next step. Although there are studies on attribute analysis in archaeological contexts, these relate to ground penetrating radar data recorded on land.

Aiming at enhancing the 3D imaging of submerged and sedimented archaeological features while preserving them in situ, a comprehensive 3D seismic attribute analysis (3DSAA) was performed. Two case studies on a late Viking wreck near Schleswig and the former monastery site Ryd Abbey in Glücksburg were conducted. The examined high-resolution data sets were collected using the PingPong 3D marine reflection seismic system, developed at Kiel University. Using IHS Kingdom 2017 software, all 68 attributes available for calculation were tested and evaluated with regards to their applicability for archaeological investigations in shallow water. The results were validated and contextualised considering previous studies on the targets.

The results show that 3DSAA is feasible for detecting and visualising archaeological assets in shallow water settings. In comparison with traditional seismic amplitude visualisation techniques, SA were able to enhance the imaging of the investigated objects conspicuously.

**SMALL-ISLAND RESILIENCE AND VULNERABILITY**

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Angliker, Erica (ICS-London) - de Angelo Laky, Lilian (Department of History University of Sao Paulo)

**Format:** Session with keynote presentation and discussion

As environmental issues have become an urgent topic, archaeologists are now turning to ancient societies to see how past communities perceived and interacted with the natural world around them and how the environment, in turn, impacted ancient societies. Along this line of inquiry, one place in particular, where the interactions between environment and human communities has proven interesting to study, is small islands. Although scholars long-believed that small islands worked as closed environments (here referring to the popular ‘island laboratory’ concept), these places are by no means cut off from external influences. Given their geographically-restricted population and natural resources, small islands – in the past, as today – are considered especially vulnerable to natural and anthropogenic hazards. Indeed, studies continue to show that the resilience of island communities is underestimated and that they remain deeply affected by high-risk situations. Small islands are more exposed than continental areas to demographic and social changes, serious earthquakes and to variations in water level, which threaten to disappear whole territories of an island, or to submerge it entirely. The culture of small islands is also deeply affected by external influences like the influx of mass tourism, which may lead to the disappearance of local traditions. This section aims to further examine how ancient people dealt with the different impacts of the environment on small islands. We welcome papers dealing with the impact of environmental changes on the demographic and social composition of small islands. We also will welcome papers that examine how the environment of the islands influenced the local culture of the islands (i.e. their religious practices, social organisation, economies, material culture and local traditions). Particularly welcome will be studies focusing on inhabited or un-inhabited islands which historically served as cemeteries, maritime strongholds, sanctuaries, pirate-hideaways, or ‘goat islands.’

ABSTRACTS:

1 RESILIENT CULTURAL LANDSCAPES AT THE SOUTHERN SHORES AND SMALL ISLANDS OF BRAZIL

**Abstract author(s):** DeBlasis, Paulo (University of São Paulo; Museum of Archaeology and Ethnology)

**Abstract format:** Oral

Sambaquis (shellmounds) are typical remnants of shoreline middle and late Holocene culturally well-adapted societies all along the Brazilian coast. Impressive mounds can be found in very productive locations (hot spots) where lacustrine, coastal islands and bay environments meet, with abundant resources from land and sea. In our study area, at the southern shores of the Atlantic coast, where lagoon settings predominate, the larger mounds have been built as enduring cemeteries, meaningful permanent sacred places where surrounding communities have continuously reenacted ritual ceremonies involving the dead (and maybe others). Some of them were active for around two thousand years, with recurrent accretion that promoted the monumental proportions they exhibit today. Located at peculiar settings (rocky islands, promontories, stable sand strands) and allowing wide visibility towards each other across the flat and open aquatic scenario, where former small rocky outcrop islands (promontories or sand barriers today) have played a decisive role in configuring socially integrated and lagoon-centered dynamic social territories, as our spatial analyses demonstrate. These mounds speak of a culturally homogeneous landscape where ancestors actively take part, linking together natural and cultural worlds.

2 A BRIEF BUT DENSE HISTORY OF A QUARANTINE ISLAND: FLAT ISLAND IN THE INDIAN OCEAN

**Abstract author(s):** Cianciosi, Alessandra (University of Amsterdam; Stanford University)

**Abstract format:** Oral

The purpose of this paper is to present a case study of Flat Island, a small completely uninhabited islet situated offshore from the northernmost tip of Mauritius.

Because of the outbreak of epidemic diseases during the nineteenth century the British Empire chose this site to construct a maritime quarantine station. Every ship suspected of a contagious infection (in particular cholera, fever, or smallpox) had to be quarantined there for a longer or shorter period before landing at the main ports of Mauritius. After this temporary and emergency use, it reverted to being uninhabited in the early twentieth century, and now it is part of the national nature reserves of Mauritius. During the last decades it has become a growing popular day-trip destination, where tourists gather on the shallow lagoon and adjoining beach along the south-eastern side of the island.

From an archaeological perspective Flat Island is a crucial site for Mauritian history, with particular reference to the migration of thousands of indentured workers from different regions of the Indian Ocean to the sugar plantations of the Mascarenes. Research fieldwork has just started to analyse the creation of an anthropic landscape and the drastic environmental transformation, characterized not only by built infrastructure, but also by the introduction of foreign species of animals and plants. The observation of spatial organization of the quarantine station, based on survey and mapping of different structural patterns, has also taken into consideration the cemetery where people who died during the quarantine were buried.

This broad archaeological project aims to retrace the short but intense anthropic history of the island, and to raise awareness and encourage the sharing of knowledge about the environmental heritage of Mauritius.

3 EXPLORING TAIWAN'S FIRST SETTLEMENT USING MODELS OF CULTURAL TRANSMISSION

**Abstract author(s):** Carrignon, Simon (Department of Anthropology, University of Tennessee; Center for the Dynamics of Social Complexity - DySoC, University of Tennessee; McDonald institute, Cambridge University) - Mesalles, Lucas (National Chung-Cheng University)

**Abstract format:** Oral

Taiwan hosts the most diverse set of Austronesian languages. From the ten recognised subgroups, nine occur exclusively in Taiwan, with particular diversity in the precipitous terrains of the Central Range mountains, a tectonically active and currently growing mountain chain. Striking similarities between language geographical distribution and geographical attributes led us to hypothesize a link between landscape barriers (e.g. mountain ridges) and connections/links (e.g. rivers), and the spread and diversification of cultural traits.

The present-day Austronesians are thought to derive from a proto-Austronesian population arrived into the Taiwan island 5.600yr BP, displacing and ultimately annihilating earlier Hòabínhiāns ("negritos") settlers. This proto-Austronesian culture is well characterized in the Taiwanese archaeological record as the Neolithic Tapenkeng corded pottery culture, and is later found in the Philippines from 4000yr BP, before spreading to the rest of Island Southeast Asia and Oceania. While archeological and linguistic evidence point to an Austronesian cultural spread starting from the Taiwan Island, the reasons behind the striking linguistic diversity of Taiwan are unknown.

In this contribution, we attempt to reproduce the Austronesian family language diversity of the Taiwanese Central Range mountains. Using an Agent-Based Model we compare different modes of cultural transmission that integrate spatial and demographic factors to reproduce Taiwan's linguistic diversity.

We test models of how the geographic distribution of the 9 languages families came about on the island, contrasting important different scenarios, including in-situ "isolation by distance" process versus any evidence for external migration at different times. Using Bayesian Inference we constrain 1/ which are the important geographical factors (slope, relief and connectivity) giving rise to the cultural diversity found on the Taiwan island and 2/ test which are the migration's scenario that are the most likely at the origin of the Austronesian dispersal into Island Southeast Asia and Oceania.

4 “THE MOST WESTERLY OF CHRIST’S FORTRESSES”: NEW RESEARCH ON THE COASTAL PILGRIMAGE TO THE ISLANDS OF SKELLIG (WORLD HERITAGE SITE)

**Abstract author(s):** Gibbons, Michael (MIAI; IQUA)

**Abstract format:** Oral

The Skelligs feature a medieval monastic complex which has been heavily conserved since the 1970s.

The earliest antiquarian discussions by O’Flaherty and Smith describe the pilgrimage to Skellig Michael as a key aspect of the site’s identity from the 17th century onwards. Historical sources repeatedly refer to the large pattern held on the island by the coastal inhabitants. Archaeological and written evidence suggests suggests this persisted in a much-diminished form into the twentieth century.

Oral reports collected in the 1930’s also refer to the practice, although mainly as a now-defunct custom, largely serving as an excuse to harass the unmarried. Despite this, comparatively little post-medieval material related to the pilgrimage appears among the recorded finds and little analysis has been done as to how the surviving built structures may have been utilized as part of the pilgrimage (outside the South Peak).

Recent field work on Skellig Michael and the Little Skellig has confirmed the presence of a small building and possible built trackway on a narrow terrace, first described by local boatman and historian Des Lavelle and subsequently by the author. The stonework suggests a building of considerable age. An overlooked 17th century account refers to a possible hermitage on the Little Skellig which may be the same structure.

During conservation, many features believed to post-date the monastic period were removed; damaging the built heritage of the post-medieval pilgrimage. The surviving oratory/hermitage on the Little Skellig may thus represent one of the only structures related to this phase to survive unaltered by 20th century conservators.

This paper will describe the available written and oral sources related to the late-pilgrimage, discuss the limited available archaeological evidence and suggest a possible connection to the structure on the Little Skellig.

5 THE SMALL ISLAND OF THASOPOULA: INSULARITY AND STRATEGIC CONNECTIONS IN THE NORTHERN AEGEAN

**Abstract author(s):** da Hora, Juliana (University of Sao Paulo - USP; University of Santo Amaro - UNISA)

**Abstract format:** Oral

This presentation aims to discuss the relations between the islands of Thasos and Thasopoula. In it, we emphasize the importance of the environmental and cultural interaction of their communities. Thasopoula is an islet that bears traces of occupation since Antiquity. Defensive structures, ceramic fragments and anthropomorphic fortifications that have been found here, allowing us to trace the strategically important movements and dynamics of the islet, which lies between Thasos and the Thracian continent.

Based on this material evidence, we raise questions about the movements of people on small island and the larger neighboring island and the relationship of this to limited resources. The material remains allow us to trace the human presence on Thasopoula from the Archaic period to the Byzantine era. A circular tower used for defensive purposes also served as a means of communication between the islands of the North Aegean and Continental Thrace. Fifth- and fourth-century BC ceramic fragments from various places in the Mediterranean reveal latent social relations between Thasopoula and Thasos, Thrace and other places in the Mediterranean. The islet remained active until modern times, and contains military remains from the second half of the 19th century, highlighting its strategic location in the Aegean. Currently, Thasopoula appears to be uninhabited, however, it still plays an important role in the management of island resources by serving as a site of transhumance of goats for Thasos. Did Thasos, one of the most important poleis in the Aegean, overshadow and dominate smaller and lesser-known islands? This paper examines whether this domination was linked to the limited resources on Thasopoula.

6 RESILIENCE AND VULNERABILITY IN A SMALL ADRIATIC ISLAND: THE CASE STUDY OF VIS IN THE CROATIAN COAST OF DALMATIA

**Abstract author(s):** Laky, Lilian (University of São Paulo)

**Abstract format:** Oral

Located in central Dalmatia in the Adriatic Sea, Vis is the most distant inhabited island from the Croatian coast. It was initially occupied by a local population, as testified by settlements dating back to the Bronze and Iron Ages. Only after the Classical period (4th century BC) did the Greeks make their presence felt by founding the polis of Issa in a natural port on the island's northeast coast. Issa was founded by Greeks from another Mediterranean island polis: Syracuse, in Sicily. The urban area of Issa has been subject to archaeological investigation, albeit partial, and scholars have been able to identify the territory of the Greek city. The history of Vis

offers an important case study of the impact of the environment on the social and demographic composition of a small island in a Greek city state. The first point of discussion here is the tiny area of the island (c.90 km2), in which the Issaeans had to coexist with settlements of the local population. The second point concerns the expansion of Issa—due most likely to overpopulation—during the Hellenistic period. The ancient Greek city state expanded to the mainland, where it founded Tragyrion and Epetion, as well as to a larger island in the region, where it established Lumbarda. Based on archaeological data on the positioning of non-Greek settlements in relation to the territory of Issa, we shall discuss how this small island environment, limited in its natural resources, may have influenced the distribution and sharing of territory between Greeks and local populations. Relying on archaeological and textual evidence, which we associate with factors known to have led numerous poleis to found sub-colonies, we shall discuss the extent to which the expansion of Issa may have been the product of the impact of a small island environment.

7 **AN ISLAND THROUGH TIME: SURFACE SURVEY AND SELECTIVE OCCUPATION ON STRONGYLO (ANTIPAROS)**

**Abstract author(s):** Levine, Evan (Brown University, Joukowsky Institute for Archaeology & the Ancient World; American School of Classical Studies at Athens) - Öztürk, Hüseyin (College Year in Athens) - Papdopoulou, Zozi (Ephorate of Antiquities of Cyclades, Hellenic Ministry of Culture & Sports) - Knodell, Alex (Carleton College, Department of Classics) - Nenova, Denitsa (The Norwegian Institute at Athens) - Athanasoulis, Demetrios (Ephorate of Antiquities of Cyclades, Hellenic Ministry of Culture & Sports) - Tankosić, Žarko (The Norwegian Institute at Athens; University of Bergen)

**Abstract format:** Oral

Since 2019, the Small Cycladic Islands Project (SCIP) has been intensively surveying dozens of uninhabited islets in the central and western Cyclades, developing a rich dataset of occupation, abandonment, and interaction from the earliest colonization of the Aegean until today. One island stands out as particularly remote and rugged, yet surprisingly rich in its material culture. Strongylo, located at the southwestern end of the island chain of Antiparos, encapsulates the benefits and pitfalls inherent in the occupation of marginal island landscapes and fundamentally informs our notions of human settlement in the Cyclades over the longue durée.

This paper presents a diachronic narrative of the occupation of Strongylo from prehistory to the present. Now completely uninhabited (except by goats), extensive terracing and damming are evidence of durable landesque capital, serving to shape the island for agricultural production and permanent settlement. At the same time, complex, multi-phase architecture reveals variable motivations for the occupation of the island through time: Strongylo provided evidence for habitation, surveillance, pastoralism, industry, and monumental construction. Moreover, the artefactual record signals a diverse range of influences and economic networks through time, underlining the island's integration into, rather than isolation from, neighboring Cycladic centers and the wider Aegean world. Thus, Strongylo offers an important case study in intensive island survey that has shown a dynamic range of activities from multiple, discreet time periods.

8 **YERONISOS OFF CYPRUS: SMALL ISLAND, BIG SEA**

**Abstract author(s):** Connelly, Joan (New York University; NYU Yeronisos Island Expedition)

**Abstract format:** Oral

Thirty years of excavation on Yeronisos off western Cyprus reveals the ebb and flow, expansion and contraction of life on a very tiny “Holy Island.” Its story is one of short bursts of vibrant use punctuated by long centuries, even millennia, of abandonment. Connected to Cyprus by a land bridge in the Chalcolithic period, the narrow promontory was used as a hunting/processing camp for the culling of fallow deer. Shortly after 3800 B.C., the land bridge collapsed and an island – one without water - was formed. Abandoned until the late Hellenistic period, the islet underwent a lavish construction program during the 1st century B.C., apparently the work of Ptolemaic army engineers from the nearby garrison at Nea Paphos. Within a few short years, Yeronisos became a significant pilgrimage destination, transformed into an island sanctuary (of Apollo?). With the collapse of Ptolemaic rule in 30 B.C., followed by a devastating earthquake in 15 B.C., the island was again abandoned, only to be reconfigured in Byzantine times as the site of a small basilica/monastic retreat. This paper tracks the interaction of the local Cypriot population with the Ptolemaic administrative presence in Nea Paphos, and across the sea to the royal court of Alexandria in Egypt and the great monastic centers of south Palestine.

9 **THE IRON AGE CYCLADES, A STUDY IN RISK BUFFERING**

**Abstract author(s):** Forsyth, Doug (University of St. Andrews)

**Abstract format:** Oral

In the central Aegean island group known as the Cyclades, evidence of interaction with areas outside of the archipelago and of intra island connectivity is observable in Iron Age (1000 – 500 BCE) contexts on many of the islands. Ceramic finds from Corinth, Athens, Euboea, Samos as well as Egyptian and Levantine items can be observed on Paros, Naxos, Andros, Siphnos, Kythnos, Amorgos, and Delos. Cycladic origin finds have been found in the Levant, Egypt, North Africa, Crete, and in mainland Greece. This is really not surprising given the location of these islands wherein travel between mainland Greece and the East necessitates transiting through the archipelago. There is more to the story however than just location. It will be argued that environmental factors, predominantly low rainfall, made habitation of these islands rather precarious from the perspective of food security. Consequently, human agency played a role in creating an entrepreneurial outlook by some of the islanders seeking to develop strong networks of affiliation with other regions perhaps to serve as buffer zones to rely on during periods of poor food productivity on the islands. Complicating a

buffer strategy was the reality that the connectivity of maritime transport was frequently broken by wind and sea conditions that prevented sailing leaving islands isolated from support. Evidence supporting this interpretation will be presented both from the archaeological record as well as ethnographic writings from later periods up to the present day. The Cyclades are remarkable in that they were both connected and isolated in turn which on certain islands fostered a human response of energetically looking beyond the islands themselves and resilience in making do with what little was available in times when external contact was prevented.

10 **NETWORKS, COMPLEXITY, AND CONSUMPTION IN THE SMALL ISLANDS OF THE AEGEAN**

**Abstract author(s):** Nenova, Denitsa (Norwegian Institute at Athens) - Knodell, Alex (Carleton College)

**Abstract format:** Oral

Small islands are often considered minor stopovers within larger important transportation networks—inactive nodes in a more extensive pathway system. The recent study of multiple islets in the Cyclades suggests that such tiny landforms participated in various extensive networks within the Aegean and beyond. The vulnerability of such places, caused by their exposure to the open sea, limited natural resources, and physical isolation from other landmasses, made connectivity essential for the survival of small-island communities. Shifts in settlement patterns within several islets indicate that the need for specific resources varied both spatially and chronologically, in a way that reflects a dynamic long-term history. This paper examines pottery evidence from several sites recently documented by the Small Cycladic Islands Project and published material from other recent survey and excavation projects in small Aegean islands. Through spatial analysis of find spots and the production locations attributed to specific vessel types, this paper explores the extent of production and consumption networks involving small-island environments and how these have varied over time. Changes in the networks modeled in this paper show that at different times small islands were alternately dependent on or isolated from larger Aegean networks of production and consumption.

11 **SETTLEMENT, LANDSCAPE AND NETWORK DYNAMICS IN THE PREHISTORY OF THE AEOLIAN ISLANDS**

**Abstract author(s):** Dawson, Helen (Dipartimento di Storia Culture Civiltà, Università di Bologna; Freie Universität Berlin) - Martinelli, Maria Clara (Parco Archeologico delle Isole Eolie, Museo Luigi Bernabò Brea) - Levi, Sara (Department of Classical and Oriental Studies, Hunter College, City University of New York) - Lo Cascio, Pietro (Associazione Nesos, Lipari) - Fiorentino, Girolamo (Dipartimento di Beni Culturali, Università del Salento)

**Abstract format:** Oral

This paper presents a critical and interdisciplinary review of the archaeological record of the Aeolian Islands (Italy), from their earliest settlement in the mid-sixth millennium BC (Early Neolithic) to the establishment of trans-Mediterranean networks at the end of the second millennium BC (Final Bronze Age). We combine archaeological, archaeometric, bioarchaeological and environmental data to explore the interplay between different prehistoric practices and their spatial settings. The resulting picture reveals different levels of interaction and the critical role of these small island communities in establishing and/or facilitating networks at the local and (inter-)regional scale. Ceramic networks allow us to trace connections between the islands and their neighbours, underscoring the centrality of the island of Lipari, which is further supported by the spatial analysis of the settlement data, in particular by the growing web of intervisibility between contemporary settlements on the Aeolian Islands, Sicily and Calabria. We also highlight significant environmental factors, such as arid phases and volcanic events, and assess their significance in light of the islanders’ responses, underscoring their long-term adaptability to the challenges of insularity.

326 **EVERYTHING YOU ALWAYS WANTED TO KNOW ABOUT PHYTOLITHS (BUT WERE AFRAID...): THEIR CONTRIBUTION TO THE MODELING OF PAST HUMAN BEHAVIOR**

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Chevalier, Alexandre (Royal Institute of Natural Sciences) - Albert, Rosa María (University of Barcelona)

**Format:** Regular session

This session aims at analyzing and shedding light on the role played by phytoliths studies for the understanding of past human behavior in relation to environment and plant uses both local and non-local, and therefore on their impact on theoretical models shaping our current understanding of human interactions with each other and with nature.

For 50 years, phytoliths have been used in archaeology to bring answers to human behavior related to territory exploitation, impact of human activities on natural vegetations, foodways, trade, transmission of cultural traits, and translocation of plants due colonization.

Phytoliths have been applied to a vast array of supports, primarily on sediments, but also to material culture, such as ceramics, metallic pots or lithic industry, and more recently to human remains, specifically on dental calculus.

But, did they succeed in bringing relevant answers to the archaeologist’s questions? Have phytolith studies been able to change our views on past human life, more than just providing anecdotal, one-time information? Did they contribute to change theoretical models regarding past human life and societies activities?

This session doesn’t aim only at phytoliths specialists working in archaeology, but also at archaeologists or other specialists who use phytoliths in their own research as many other lines of evidence.

Hence, this session calls for communications that show evidence of such impacts of phytolith studies on our understanding of past human behavior, actions and interactions. Key questions are : What are the strengths and weaknesses of phytoliths? What is exactly their potential? How are they changing our views on the past? To which new analytical approaches do they contribute? What are our expectations about their future potential?

The session is sponsored by the Society for Phytolith Research and it organized in parallel to the IMPR, but it is not formally part of it.

ABSTRACTS:

1 SILICEOUS MICROREMAINS, GEOCHEMICAL MAGNETIC AND MINERALOGICAL ANALYSES OF CORE MATERIAL FROM KILOMBE CALDERA (KENYA), PROXY QUATERNARY PALAEOENVIRONMENT, CONTEXTUALISING HOMININ OCCUPATION

**Abstract author(s):** Albert, Rosa Maria (ICREA - Catalan Research for Research and Advanced Studies; Dep. of History and Archaeology, University of Barcelona) - Hoare, Sally - Stanistreet, Ian - Gowlett, John (University of Liverpool, ACE) - Stollhofen, Harald (GeoZentrum Nordbayern, Friedrich-Alexander-University - FAU - Erlangen)

**Abstract format:** Oral

Quaternary lacustrine sequences from East Africa are important archives of orbitally forced paleoclimatic changes, which effects lake-level limit and palaeovegetation, which are considered to control hominin occupation of and evolution within East Africa. Here we investigate in detail a well preserved and fairly continuous lake sedimentary sequence from Kilombe Volcano (Kenya), whose caldera-fill also preserves traces of hominin activity at several localities, involving Oldowan and Acheulean technologies. Our goal was to examine palaeoclimatic and palaeoenvironmental conditions using microbiological and geochemical analyses of bulk sediment samples from lacustrine units in the caldera fill, and its influence on hominin occupation. Microbiological analyses include the identification of various siliceous microremains preserved in the sediments such as phytoliths, diatoms and sponge spicules. Changes in chemical weathering intensity are examined using a multi proxy approach including major and trace element ratios (Chemical Index of Alteration, WIP); Fe-oxide mineralogy (S-ratio, D FD%); and Total Organic Carbon. The identification of phytoliths, diatoms and sponge spicules record vegetation presence and environmental conditions (lake regressions and transgressions) that vary through time. The magnetic and geochemical properties of the clays document from incipient through to intense changes in catchment weathering. Combined results record palaeoclimatic and palaeoenvironmental change during the Quaternary.

2 ARCHAEOBOTANICAL TAPHONOMY AND ARCHAEOLOGICAL INTERPRETATION. PHYTOLITH, SEED, AND CHARCOAL REMAINS FROM THE EARLY UPPER PALAEOLITHIC SITE OF MUGHR EL-HAMAMAH (JORDAN)

**Abstract author(s):** Alonso-Eguiluz, Mónica (ERAAUB Equip de Recerca Arqueològica i Arqueomètrica de la Universitat de Barcelona) - Albert, Rosa Maria (ICREA Research Professor; ERAAUB Equip de Recerca Arqueològica i Arqueomètrica de la Universitat de Barcelona) - White, Chantel E. (University of Pennsylvania) - Asouti, Eleni (University of Liverpool) - Boaretto, Elisabetta (Kimmel Center for Archaeological Science - Weizmann Institute of Science) - Nilsson Stutz, Liv (Linnaeus University) - Stutz, Aaron (Bohusläns Museum)

**Abstract format:** Oral

Post-depositional processes invariably lead to degradation and alteration of the archaeological record. The Mughr el-Hamamah site (Ajlun Governate, Jordan) highlights the potential for taphonomic analysis of macrobotanical remains from contexts often considered too old to preserve such archaeobotanical traces, thus complementing phytolith analysis. Charcoals and legume seeds have yielded radiocarbon dates, placing the Early Upper Palaeolithic (EUP) occupation between 45-39 ka cal BP. The EUP Layer B incorporates micro- (phytoliths) and macrofossils (wood charcoal, seeds and nutshell). However, Layer B has also been subject to significant post-Palaeolithic disturbance from 20th century goat-penning activity).

We present a multi-proxy archaeobotanical study of Mughr el-Hamamah Layer B. Phytolith samples reveal the distribution of modern goat spherulites, showing very limited mixing between recent goat dung deposits and the Palaeolithic Layer B. A similar pattern is shown by the analysis of intrusive insects and modern seeds found in macrobotanical samples. Phytoliths contain both C3 and C4 plants, indicating generally humid conditions with dry spells or arid microenvironments. We documented inflorescence phytoliths, produced during the June blooming season, suggesting, at least, summer use of the cave. Dicot phytoliths and wood charcoals indicate the use of wood fuel, while fruit phytoliths are also present in soil samples taken from hearths. Macrobotanical results indicate the presence of legume seeds, Pistacia nutshell, and wood charcoals (oak, Pistacia, and almond wood). The direct dating of well-preserved charcoals and seeds anchors our understanding of site formation processes at Mughr el-Hamamah by confirming the antiquity of the macrobotanical remains, while the integrated study of micro- and macrobotanical assemblages has mapped the nature and range of post-Palaeolithic intrusions. Our systematic evaluation of archaeobotanical taphonomy permits a robust characterization of the EUP site environment and human uses of plants for food and fuel.

3 MICROBIOMORPHIC (PHYTOLITH) ANALYSIS IN THE GEOARCHAEOLOGICAL STUDY AT THE VOORTHUIZEN-WIKSELAARSEWEG ARCHAEOLOGICAL SITE (NETHERLANDS)

**Abstract author(s):** van den Berghe, Kasper (Herzen State University; FindX) - Druzhinina, Olga (Herzen State University) - Golyeva, Alexandra (Institute of Geography RAS)

**Abstract format:** Oral

Phytolith analysis, from the first application to study the genesis of Russian chernozems in 1850, has been successfully used in soil science, paleoecology, botany, and archaeology. And although the latter has been actively using the achievements of the method since the 1970s, phytolith analysis still remains unknown to the vast majority of archaeologists in the Netherlands.

Meanwhile, phytoliths are an essential source of information different from that provided by the study of pollen. While palynological research gives a general insight into plant growth in the region around settlements, phytoliths (plant cell silica copies) present data on the plant species grown, eaten, and used on the settlement itself. This information is contained in the old living layer, as well as in pits (working places and waste pits), postholes, ditches, etc.

Microbiomorphic method of analysis, as a follow up of the phytolith analysis, combines data on phytoliths and other microbiomorphs (ex. plant detritus, diatoms, fungi, etc.) determined in archaeological samples, which further expands the scope of palaeoecological information.

Microbiomorphic analysis was applied as a pilot project to the study of the Voorthuizen-Wikselaarseweg archaeological site, dated to Iron Age and Roman times, located in the central part of the Netherlands. 34 samples have been collected and processed according to the standard sample treatment technique (Golyeva, 2008). All samples were found to be suitable for analysis, with a sufficient number of microbiomorphs.

The study results clarify the available archaeological information on the site and provide new insight on the anthropogenic impact on the landscape manifesting the existence of several phases and types of anthropogenic use of the territory. The research also demonstrates the applicability of microbiomorphic (phytolith) analysis in the case of sandy archaeological layers, which are assumed to bear worse conditions of preservation of traces of anthropogenic activity.

4 THE CONTRIBUTION OF PHYTOLITHS TO THE UNDERSTANDING OF THE HUMAN ACTIVITIES ENTANGLED IN THE EN POTTERY OF NORTHERN GREECE

**Abstract author(s):** Papadakou, Trisevgeni (Aristotle University of Thessaloniki) - Tsartsidou, Georgia (Ephorate of Palaeoanthropology-Speleology, Hellenic Ministry of Culture, Athens; The M.H. Wiener Laboratory for Archaeological Science, ASCSA) - Papadopoulou, Lambrini (Geology Department, Aristotle University of Thessaloniki) - Kotsakis, Kostas - Valamoti, Soultana-Maria (Department of Archaeology, Aristotle University of Thessaloniki) - Urem-Kotsou, Dusanka-Christina (Department of History and Ethnology, Democritus University of Thrace)

**Abstract format:** Oral

Phytoliths trapped in the pottery matrix as a result of deliberate addition of plant-derived materials and/or as inadvertent inclusions have been extensively and very successfully studied to address a variety of questions which broadly correspond to two main axes of interest: organic-tempered pottery as material culture, tackling issues such as production and circulation, cultural contacts etc., and organic temper as archaeobotanical evidence. Pertaining to the former line of questioning, the case-study of six EN pottery assemblages from northern Greece presented herein, spanning approximately the 2nd half of the 7th millennium, highlights how the study of phytoliths as markers of human activities can help us explore the convergence and entanglement of different aspects of the Neolithic way of life, and inform us on the practices involved in the construction of these vessels. The organic-tempered pottery, comprising only a small fraction of these assemblages, was examined in regard to the temper's botanical signature using petrographic thin sections and manually extracted material observed under the SEM, and the two methods employed are assessed and compared as to their efficacy regarding the specific research questions. The results hint at a link between the production of organic-tempered pottery and food preparation, revealing at the same time some potential of both inter- and intra-site variability.

5 THE BUDDING OF PLANT MICROFOSSIL RESEARCH IN ESTONIA

**Abstract author(s):** Unt, Agnes - Niinesalu, Maris - Johanson, Kristiina (University of Tartu)

**Abstract format:** Oral

The potential of studying archaeological plant microfossils in determining past human foodways in Estonia has so far been underused, however, the need for adapting a suitable method for our material is increasing. Our small work group is currently making first steps to analyse foodcrust and dental calculus from different sites, with the specific focus on starches and phytoliths.

To do this effectively, we are building a reference collection of starches and phytoliths of Estonian food plants, an area mostly unmapped by plant microfossil reference collections. We are focusing on different methods of processing to determine changes in phytoliths and starches such as chewing, crushing and boiling among others.

In our presentation we will introduce the first results of selected case studies from Estonia in regard to phytoliths and starches. Some of these sites have been or are being analysed with other methods, e.g. stable isotope analysis of human bones or lipid residue analysis of pottery, and the results of plant microfossils would help to support or challenge these results.

6

COLONIAL ERA AND AFRICAN-AMERICAN SLAVE FEATURES IN SOUTH CAROLINA: A RECORD FOR COMPARISON

**Abstract author(s):** Scott Cummings, Linda (PaleoResearch Institute)

**Abstract format:** Oral

An 18th to 19th century plantation in South Carolina included Colonial era trash pits, wall trenches, and storage pits. A nearby African-American slave settlement, dating to the mid-1850s, is represented by an Antebellum wall trench and an Antebellum and Post-bellum trash pit. These features were examined using pollen, phytolith, and starch analysis for evidence of economic activity, with the opportunity to compare those records of food and resources between the Colonial era and African-American slave features. Together they provide a record of vegetation that describes the local forest and understory vegetation at the time of occupation that included both native and weedy (Amaranthaceae, Ambrosia-type, and Liguliflorae) plants that might have been important as food and/or medicinal resources. The phytolith record identifies the presence of cool and warm season grasses that prefer cool, shady or hot, sunny habitats. Cereal grain cultivation and use is documented at both sites in both the pollen and phytolith records, indicating this staple was available to and used by both populations. Maize (*Zea mays*) is documented in three trash features and two storage pits, spanning both locations. Various native plants such as Virginia creeper (*Parthenocissus*) and poison ivy (*Toxicodendron*) are represented in storage pits, suggesting the possibility that Virginia creeper berries were stored and raising the question of the value of poison ivy as a medicinal. One principle in medicinal application is that plants may be used to treat conditions or symptoms that are similar to the ones they cause. In this case, itching, blistering, and oozing discharges also are observed in chicken pox, shingles, herpes, dermatitis, eczema. The use to which poison ivy might have been put remains a mystery, but either it was collected and stored in this pit or it grew out of the pit immediately after abandonment.

7

NEW METHODS TO REDUCE THE UNCERTAINTY IN MICROARCHAEOLOGY

**Abstract author(s):** Andreu Diez, Oriol (University of Barcelona) - Albert Cristóbal, Rosa María (ICREA; Universitat de Barcelona) - Boaretto, Elisabetta (Weizmann Institute of Science) - Pellicer Moscardó, Jaume (Institut Botànic de Barcelona - CSIC)

**Abstract format:** Oral

Phytolith analyses and the study of other microremains such as calcium oxalates, spherulites, starches, etc. have been shown to be critical to better understand past and vegetation landscapes directly related to human activities and use of plants. Nevertheless, there are still some limitations that have directly affected our research and that we believe we are currently in a position to address, thanks to the advance of other related disciplines. These limitations are, i) preservation and dissolution of siliceous and calcitic microscopic remains that may affect our correct interpretation of the archaeological record; ii) the problem of redundancy and multiplicity of phytolith morphologies that may elude a precise taxonomic identification; iii) the uncertainty regarding the source of the occluded carbon present in the phytoliths and, therefore, its reliability for 14C dating. To do this, we propose a methodological approach divided into two fields of action. Firstly, the implementation of the latest advances in computer science and artificial intelligence, using Deep Learning algorithms (Convolutional neural networks) to classification tasks. Then, introducing the application of techniques from other scientific disciplines such as cytogenetics (i.e. flow cytometry), and radiocarbon dating methods (Accelerator Mass Spectrometry) that will complement and expand the multi-proxy microarchaeological approach to improve the understanding of the phytolith production processes, and the interpretation of results, in particular, to improve the taxonomic identification of phytoliths.

We prospect that the implementation of this novel methodological approach will allow us to advance further in our research. In particular, our objective is to apply our results to better understand two different fields of research: a) agriculture as a driver of social change and b) the characterization of fuel in archaeological sites.

327

ENGENDERING PUBLIC ARCHAEOLOGY [AGE]

**Theme:** 3. The new normality of heritage management and museums in post-Covid times

**Organisers:** Masriera-Esquerri, Clara (Universitat Autònoma de Barcelona - UAB; Universitat de Barcelona - UB) - González-Marcén, Paloma (Universitat Autònoma de Barcelona - UAB) - Díaz-Zorita Bonilla, Marta (Eberhard Karls Universität Tübingen) - Colomer Solsona, Laia (Norsk institutt for kulturminneforskning)

**Format:** Regular session

Since Public Archaeology examines the role and impact of archaeological activity in a wider social, economic and political aspects, this session would like to add a gender perspective to this examination. Public Archaeology focuses both on how the discipline engages the public in archaeological matters, both research and interpretation of heritage, and on how the public uses archaeological heritage for social, political, educational, and cultural matters. This session aims to explore the inclusion of a gender perspective to this reciprocal relationship, in both theoretical and practical terms. We look for contributions that examine gender politics, roles, norms, and stereotypes present openly and subtly in the practice of public archaeology. But also, contributions that explore these within the theory of practicing public archaeology, and in the practice of theorizing about public archaeology. The session aims thus to engage in the debate of gender values and attitudes attached to archaeological practice for the public, and how these engendered practices and discourses are transferred accepted, maintained, negotiated, and contested by society. Therefore, we envision

this session as a meeting place to discuss theoretical approaches and practical experiences focused on gender and feminist perspectives.

Areas of interest for this session on gender/feminism in public archaeology include, but are not limited to, the following topics:

- Public engagement activities in archaeology/heritage
- Collaborative practices and digital networking
- Results of scientific research and the impact of archaeology in the media/social media
- Participatory and engendering archaeology/heritage projects
- Gender perspectives in community heritage/archaeology
- Gender perspectives in archaeological museums and heritage management and interpretation practices
- School/university curriculums and educational practice of archaeology
- Gender perspectives in teaching public archaeology at university level
- Professional and academic cultures

ABSTRACTS:

1

FEMINIST PERSPECTIVES IN ACTION: LOOKING FOR GENDER IN PUBLIC ARCHAEOLOGY

**Abstract author(s):** Gonzalez-Marcen, Paloma (Centre d'Estudis del Patrimoni Arqueologic de la Prehistoria; Universitat Autònoma de Barcelona)

**Abstract format:** Oral

In the last decade there has been a significant growth, both qualitative and quantitative, of academic contributions in the field of gender archaeology. However, if we assume that the development of gender archaeology parts of a search for a critical and informed representation of gender, and particularly women, in the historical narratives, broadly understood as instruments of knowledge, reflection and action, there is surprisingly little and / or poor visibility of gender perspectives in the field of so-called public archaeology.

In this presentation I intend, first, to reflect on why the journey from feminist activism to gender archaeology seems to have become a one-way one, with few return tickets; secondly, I want to discuss the academic difficulties that activist researchers may encounter for making their actions both visible and relevant, and, thirdly, to provide examples and proposals for a higher incidence of gender archaeology in different areas of contemporary society.

2

GENDER ROLES IN ARCHAEOLOGICAL EDUCATIONAL ACTIONS

**Abstract author(s):** Masriera-Esquerri, Clara (Universitat Autònoma de Barcelona; Universitat de Barcelona) - Cacheda-Pérez, Maria (Universitat Autònoma de Barcelona - UAB)

**Abstract format:** Oral

The educational potential of archaeology increases when the target audience is children. For this sector of the public, educational actions are based mainly in different kinds of manipulative activities and the use of representational images. However, on the one hand, many hands-on activities tend to stereotype traditional notions of technology and gender tasks division and, on the other hand, most graphic materials that are available are designed to "simplify" scientific discourse implying that gender stereotypes become much more marked even than in representations for a general public.

It is also necessary to understand that in formal or informal educational settings the use of hands-on activities and representational images are entwined with other communicative variables and contexts which structure the educational action. In this presentation we propose to analyse these educational actions that are carried on in school, museum and archaeological heritage contexts and reflect on the implications of the different variables from a gender perspective.

3

ARCHAEOLOGICAL HERITAGE AS TEACHING CONTENT IN PRIMARY EDUCATION. A CASE STUDY BASED ON SOCIAL SCIENCES TEXTBOOKS IN THE CANARY ISLANDS

**Abstract author(s):** Farrujia de la Rosa, Jose (Universidad de La Laguna)

**Abstract format:** Oral

Textbooks are the main material resource for Primary Education in Spain, in the case of formal schooling. Textbooks are also the materialization of the published curriculum and, therefore, they contribute to the official and pedagogical knowledge in schools. That is to say, textbooks contain the information that students need to study in order to pass a subject and, in addition, the textbook is the subject guide.

Despite the variety of teaching resources available in the educational field, the technological advances and the various educational reforms that have taken place in Spain in recent years, textbooks are currently the main resource in which supports teaching. According to data from the Spanish Evaluation Institute of the Ministry of Education, this resource is used by 99.1% of Primary Education students.

Taking into account the importance of textbooks as teaching resources in the classroom, this communication analyzes how Canarian archaeological heritage is focused, as educational content, within the Primary textbooks of Social Sciences. This analysis

will take into consideration key aspects such as: what is considered archaeological heritage in teaching, how and what is taught, and what is the role of women in the historic fact and in the educational content. The main results of this research show the pre-dominance of the androcentric cultural hegemony, the reproduction of Eurocentric views, the absence of an explicit definition for the archaeological remains and, therefore, for the concept of heritage. This panorama is similar to that registered in the rest of the Spanish State and in Latin America.

4 GENDER IN PUBLIC ARCHAEOLOGY: FEMININE DISCOURSES IN RURAL LESBOS

**Abstract author(s):** Beka, Georgia - Galanidou, Nena (UOC)

**Abstract format:** Oral

We present research on the reception, conceptualisation, and appropriation of the Paleolithic heritage in insular Greece. In the context of Palaeolithic Lesbos, a project which conducts systematic excavation at Acheulean Lisbori-Rodafnidia on Lesbos island, we have been working with the local rural community to explore how it appropriates its archaeological heritage. Our work lies at the heart of Public Archaeology’s attempt to give voice to the local community and bring it to the forefront of archaeological investigation. We are interested in deciphering the ways the local community receives and remakes archaeological meanings and interpret the “Paleolithic past” as “cultural heritage”. Our ongoing research examines how different social categories (e.g. women, men, immigrants, young islanders, older people) of the farming community at Lisvori appropriate and narrate the “Palaeolithic past” and what importance they attach to it. In order to investigate the their discourse and viewpoint on the emerging cultural narrative, we have used the ethnographic method for data collection and what is largely a qualitative approach.

In this paper we place under our magnifying lens the interaction between the archaeological team and the local community to discuss how identity construction and narration with reference to the Palaeolithic past are differentiated across gender groups. Of particular interest is the role of woman-the-archaeologist heading work in the field, playing a key role in a public discourse that is expected to be the man’s domain, and thus challenging the stereotypical expectation of a director of field operations. Of equal interest is woman-the-farmer – which reveals a “buried” dynamic in her bio-history and connects with the archaeological team through the shared endeavour of “digging”.

5 ENGENDERING BLACK LIVES MATTER’S REASONS

**Abstract author(s):** Colomer, Laia (NIKU)

**Abstract format:** Oral

In Spring 2020 we witnessed a radical act of public engagement with cultural heritage: political activists from the Black Lives Matter-movement tumbled monuments and statues of eminent men but with a racist colonial past. The actions were a performance against the deep-rooted structural racism and its neglected divisive in cultural heritage. However, a feminist analysis to these monuments would acknowledge that they also embed other ‘politically incorrect’ narratives: they are perfect iconographies of whiteness and maleness normativity. Among critical heritage scholars, the BLM performance raised many discussions on the appropriateness of topping down these monuments, but little, if none, of the arguments given angled it from a gender or feminist perspective. I will argue that these statues do not anymore reflect today’s society ideals in relation to genders, that they have become an archaeological element by themselves commemorating distant pasts at all levels, and therefore they are open to become also contested spaces for a hypothetical Women Lives Matters-movement.

6 DISSECTING GENDER FROM BELOW IN SPANISH [PUBLIC] ARCHAEOLOGY

**Abstract author(s):** Zarzuela, Paloma - Pastor Pérez, Ana (Universitat de Barcelona - UB, Group of Public Archaeology and Heritage)

**Abstract format:** Oral

This paper is intended as a conversation between two activist archaeologists from contiguous generations. Our aim is to discuss how current feminist and gender agendas are relevant to the archaeological practice today and whether these can meet the premises of Public Archaeology. Here we propose to share intersectional views, dissidences, common struggles or common fractions: from management archaeology studies to social movements; from archaeologies from below to elitist forums.

Are we promoting gendered public archaeology without noticing it? The book “Public Archaeology in Spain” (Arqueología Pública en España) edited by Jaime Almansa Sánchez was published in 2013. For the first time in Spain, a volume gathered together a series of scattered topics related to Public Archaeology. This publication provided an “umbrella” under which management, new technologies and social studies could converge. Scholars spread awareness about the importance of the role of the society as actors rather than as passive recipients of archaeological outputs and knowledge. However, are these interactions embedded with the current trends in gender and feminist archaeology?

This dialogue examines and defines gender issues within participatory and community archaeology. Our conversation is based on the analysis of various extraordinary actions in which we participated and our ordinary lives. New synergies and joint lines of work are expected to flourish. Todas estáis invitadas.

7 CRETAN ARCHAEOLOGY OF THE 1950S AND THE 1960S: AN ENGENDERED ENDEAVOUR

**Abstract author(s):** Gkazi, Ariadni (University of Crete)

**Abstract format:** Oral

This paper casts a gender perspective on Public Archaeology in Crete during the 1950s and the 1960s, a period in which official archaeology sharpened its profile and was widely established as the guardian of the archaeological heritage of Greece. This took place against a rapidly changing economy and a society which saw tourism and the infrastructure required to support it as the silver lining in the cloud of post-war poverty. During the period in question, the protagonists of archaeology in Crete in charge of the major excavation operations and public outreach, were all men; the extremely few female archaeologists certainly did not hold high positions in the hierarchy of the local Ephorates. The protection and the management of the sites and monuments of Crete, officially attributed to the Archaeological Service, was thus a man’s task. As was it a man’s job to speak about the past and defend it in the public sphere. In this paper I discuss the activity of two male figures of Cretan archaeology, Nikolaos Platon and Stylianos Alexiou, and examine notions of power, honour, pride, hospitality, hierarchy and submission in the wider context of relations between the official archaeology in Crete, Cretan society and central government. These notions are shown to be critical in the way archaeological practitioners defended the archaeological heritage of Crete against destruction. They formed an ethos, shared with fellow Cretans, that often helped them to forge alliances with the local administrative authorities, the press, and cultural organizations so as to exercise more pressure towards the Directorate of the Archaeological Service in Athens and strengthen their claims for more personnel, funding for excavations etc., which in certain cases, as will be presented in the paper, led to fruitful results.

8 SEXUAL VIOLENCE IN ANTIQUITY THROUGH ARCHAEOLOGICAL MATERIAL

**Abstract author(s):** Akkaya, Ecem (Independent researcher)

**Abstract format:** Oral

Ancient Greek mythology and literature consists of many events that can be described as “rape” when viewed from today. These scenes have been defined in the literature as rape, pursuit or abduction. The main discussion of the study is relationship between visual representation and gender in ancient societies. The main question of my thesis is; Can we say that sexual violence was accepted in the Aegean world in Antiquity by based on the concept of sexuality accepted today? In my study, I benefit the approaches of postmodern feminist theory to sexuality, representation and gender, Social anthropology, psychology and media studies in the evaluation of these material data. The material is interpreted by studies on the relationship between identity, gender and representation in modern literature. At the same time, Greek mythology and literature will be used. The study uses the methods of gender archeology and feminist archeology studies developed within post processual archaeology in the broadest sense. The basis of the study is Andrew Stewart’s article “ Rape?”. In his article, Stewart focuses on pursuit scenes on 5th-century Athens vases. He also touches on whether these scenes could be directly described as “rape”. Edward Harris’s “Did rape exist in ancient Greece? Further Reflections on the laws about Sexual Violence” is a study of the ancient Greek society’s attitude of rape and sexual violence. Keuls, in the book “Phallus Reign” emphasizes B.C. 5th century Athens vase paintings and examines them in the context of “phallocracy” and rape culture. In my study, which is a compilation based on published material, I will discuss the subject by prioritizing the archaeological material. The main contribution of this study is to examine scenes defined as rape and pursuit more comprehensively in the context of representation and gender.

330 THE CARPATHIAN BASIN AS A MELTING POT? PERSPECTIVES ON SOCIAL AND CULTURAL DIVERSITY FROM THE NEOLITHIC TO THE BRONZE AGE

**Theme:** 4. Globalisation and archaeology

**Organisers:** Szilagyi, Kata (Mora Ferenc Museum, Szeged; University of Oslo, Institute of Archaeology, Conservation and History) - Furholt, Martin (University of Oslo, Institute of Archaeology, Conservation and History) - Hofmann, Robert (Kiel University, Institute of Pre- and Protohistoric Archaeology) - Depaermentier, Margaux (Archaeological Institute, Department of Early Medieval and Roman Provincial Archaeology, University of Basel) - Kempf, Michael (Institute of Archaeology and Museology, Faculty of Arts, Masaryk University)

**Format:** Regular session

The session focuses on the Carpathian Basin as a social and cultural melting pot during the Neolithic, Chalcolithic and Bronze Age. Due to its location at the interface of diverse environments and historical landscapes it had the character of a contact zone and was an arena for numerous instances of interaction, which resulted in manifold forms of material culture linking distinct parts of Eurasia. In the past, archeologists aimed to tackle the challenges of interpreting the materials by creating various cultural groups and studying their chronological positioning. In the last decades new research methods (e.g. Bayesian approach of radiocarbon dating, multidisciplinary field survey, aDNA) together with new theoretical perspectives provided the means of studying materials, sites or microregions in a refined fashion. As a result, the prehistoric narratives of regional and supra-regional level have become increasingly detailed (event-based resolution). The arising challenge is twofold: firstly, the integration of heterogenous datasets and contradictory perspectives on the past, secondly, to implement findings into scientifically-sound concepts (social organization, landscape perception, technological studies), and, lastly, to integrate the dynamics of the distinguished aspects.

The aim of this session is to discuss the details of transmission and transformation processes from the social archaeological perspective, compare the different periods and focus on diachronic change. We would like to consider the ways of integrating legacy and recent datasets towards answering new questions related to the Carpathian Basin.

We welcome contributions to the following questions:

- How did new traditions, ideas and practices spread between the Carpathian Basin and adjacent regions?
- How can different research methods be used to formulate coherent models on settlement patterns, natural environment and social organization?
- How can we quantify the scales of the transformation in different periods?
- How are current research models and theories affecting the interpretation of past findings?

ABSTRACTS:

1 TAKE A SEED! TRACING NEOLITHIC AGRICULTURAL DEVELOPMENT IN THE CARPATHIAN BASIN THROUGH MULTIVARIATE STATISTICS AND ENVIRONMENTAL MODELLING

**Abstract author(s):** Kempf, Michael (Masaryk University Brno)

**Abstract format:** Oral

The Carpathian Basin represents the cradle of human agricultural development during the Neolithic period, when large parts were transformed into cultural landscapes by first farmers from the Balkans. It is assumed that an Early Neolithic subsistence economy established along the hydrologic systems and on Chernozem soil patches, which developed from loess deposits. However, recent results from soil chemistry and geoarchaeological analyses raised the hypothesis that extensive Chernozem coverage developed from increased land-use activity and that Early Neolithic cultural groups were not restricted to loess-covered surfaces but rather preferred hydromorphic soils that developed in the floodplains. This article performs multivariable statistics from large spatial datasets of Neolithic sites in Hungary and allows tracing Early to Late Neolithic site preferences from digital environmental data. Quantitative analyses reveal a strong preference for hydromorphic soils and a significant avoidance of loess-covered areas and Chernozem soils throughout the Early Neolithic followed by a transformation of site location preferences during the Late Neolithic period. These results align with socio-cultural developments, large-scale mobility patterns, and land-use and surface transformation, which shaped the Carpathian Basin and paved the way for the agricultural revolution across Europe.

2 AGRICULTURE, REGIONAL VARIATION AND THE DEVELOPMENT OF SOCIAL INEQUALITY IN THE CARPATHIAN BASIN

**Abstract author(s):** Duffy, Paul R. (The Archaeology Centre, University of Toronto; Italian Academy for Advances Studies in America, Columbia University) - Johannsen, Niels (Department of Archaeology and Heritage Studies, Aarhus University)

**Abstract format:** Oral

The ‘ard’ or scratch plough may have had major transformative consequences – not only for agriculture but, perhaps to a surprising degree, for the emergence of social inequality in prehistoric Europe. Archaeologists have long sought to identify the conditions under which social inequality first emerged in Europe. Some suggest that the rise of a class of warrior people, who controlled trade across Bronze Age Europe in a way that benefited some and not others, was responsible. In recent years, however, tantalizing evidence has suggested that the plough was both the spark and the fuel for inequality in the Old World. In this paper, we assess the physical evidence for plough agriculture at tell settlements in Hungary, Serbia, and Romania. We model the population numbers local agriculture would have supported at these tells, using grain production estimates of different agricultural regimes. We estimate the degree of social inequality each of them likely sustained by comparing the consumption and production of prestigious goods between them. Finally, where available, we discuss the mortuary data from cemeteries near to tell populations to estimate the extent to which local communities experienced inequality. Together, we hope to highlight the ways in which plough agriculture was intertwined with emerging social inequality during the Bronze Age, and the paths in which plough agriculture played a minor role.

3 PLANTS AS A REFLECTION OF SOCIAL AND CULTURAL DIVERSITY?! CONSIDERATIONS OF PAST AND RECENT MACROBOTANICAL DATA FROM BRONZE AGE HUNGARY

**Abstract author(s):** Filatova, Sofia - Kirleis, Wiebke (Institute for Prehistoric and Protohistoric Archaeology, Kiel University)

**Abstract format:** Oral

Macrobotanical remains from excavations at Bronze Age sites in Hungary have been studied intensively during two phases: the 70s and 80s, and the 90 and the first decade of the second millennium. An obstacle that is unavoidable with macrobotanical studies that span several decades, is that the research methods (e.g. sampling strategies, interpretations of assemblage composition) have altered through time and thus the reliability of the data is diverse. Regardless, these studies, summarised by Ferenc Gyulai in his publication on archaeobotany in Hungary, have contributed valuable knowledge about the diversity of plants represented for the Bronze Age in the region. To a great extent, the interpretations of these datasets have been closely related to the archaeological groups defined for the Bronze Age in the Carpathian Basin, and thus besides being distinguished based on ceramic styles, burial customs, and settlement patterns, the archaeological groups are further ascribed specific spectra and proportions of crops.

Between 2013 and 2016, excavations of the tell-like settlement Kakucs-Turján (Central Hungary) yielded a large amount of systematically sampled macrobotanical remains that were related to Nagyrév and Vátya occupation layers of the Early and Middle Bronze Ages, respectively. The material allowed for a detailed reconstruction of macrobotanical formation processes and plant economy throughout the eleven habitation phases of the settlement. The insights from this study can be used to gain a further understanding of Bronze Age crop spectra and plant-cultivation practices on a local, household scale and underline the challenges related to summarising and interpreting archaeobotanical data on the (regional) scale of the archaeological groups. It further shows that the tiny and frequent remains of plants from archaeological sites represent valuable contributions to the investigation of social and cultural diversity during the Bronze Age.

4 LIKE A SAILING STONE: „CULTURAL“ CHANGE DURING THE NEOLITHIC OBSERVED IN LANDSCAPE TRANSFORMATION IN THE AREA OF GORJANI, CROATIA

**Abstract author(s):** Sosic Klindzic, Rajna (University of Zagreb Faculty of Humanities and Social Sciences) - Kalafatic, Hrvoje (Institute of Archaeology Zagreb) - Hrsak, Tomislav (Archaeological Museum Osijek) - Šiljeg, Bartul (Institute of Archaeology Zagreb)

**Abstract format:** Oral

Image of Neolithic people living simple peasant life in a small helmets was dominant interpretation for the last 150 years. Evidence of complexity and evidence of large sites were often perceived as special and/or unique. In the last two decades new evidence emerged from various types of research: large scale infrastructural work revealed large area of settlements and availability of aerial imagery showed much larger number of large and complex Neolithic sites than previously thought. As in many other parts of Europe, recent research in Eastern Croatia revealed great number of such sites as well. Here we will present area around village Gorjani in Slavonia, Croatia during the Neolithic period.

Using combination of geophysical research (magnetic survey), satellite imagery, coring, field survey, radiocarbon chronology and pottery analysis, new patterns of spatial organization and cultural transformation began to outline. We will also use comparative analysis of modern settlements in the area and their transformation during last several centuries to evaluate its appropriateness to serve as a proxy for understanding how prehistoric societies, settlements and landscape transformed during time.

5 THE NEOLITHIC LANDSCAPE: A SCENE FOR THE CULTURAL DIVERSITY OF NORTHEAST HUNGARY BETWEEN 6000-4500 BC

**Abstract author(s):** Füzesi, András (Eötvös Loránd University)

**Abstract format:** Oral

The cultural diversity of the Carpathian Basin is clearly demonstrated by changes in ceramic decorations. Ferenc Tompa and Gordon Childe already paid close attention to this phenomenon in their definitive monographs (1929). This cultural diversity coupled with a very mosaic environment of the Carpathian basin, which correspondence suggested a kind of causality between these conditions. The analytical archaeology with its distinct methods was able to demonstrate such correlations, mapping cultural groups and environmental regions with definite boundaries. The new concept of landscape theory in connection with system and entanglement theory, taskscape, and network analysis offers a wider and more complex framework of the interpretation. Among the different (ecological, cultural, economic, and symbolic) aspects of the landscape, a host of connections exists, sprouted from the societies that created those landscape phenomena.

In such a wide region like Northeast-Hungary, many microregions coexisted in every archaeological period with different ecological backgrounds and social-cultural traditions. Polgár Island is a prominent micro-region in this area, which has been investigated by the ELTE Institute of Archaeological Sciences since 1989. Its cultural diversity throughout the Neolithic reflects a special strategic position. Many other microregions, like Füzesabony, Rétköz, Bodrogköz, existed in the Neolithic period and had a diverse cultural identity. The creation of these identities was running parallel to and through the creation of the local landscapes. Connections between landscape and culture are multivariate and based on their concepts: Landscape created by humans within the environmental framework and Culture created also by humans because of the environmental restrictions.

6 MERGING TOGETHER OR MELTING AWAY? NEOLITHIC TRANSITIONS IN THE NORTHERN MAROS FAN, HUNGARY

**Abstract author(s):** Salisbury, Roderick (University of Vienna, Dept. of Prehistoric and Historical Archaeology; Austrian Academy of Sciences) - Bácsmegi, Gábor (Munkácsy Mihály Museum, Békéscsaba)

**Abstract format:** Oral

The Carpathian Basin in prehistory was a ‘melting pot’ of cultural elements, people, and materials. For the Middle Neolithic (Hungarian chronology, c. 5500-5000 BC), the Linearbandkeramik phenomenon has dominated archaeological interpretations. This focus on one supposedly preeminent cultural group generates challenges for interpreting diverse materials and chronological positioning in the eastern Carpathian Basin. Here, the eastern LBK variant might not have been as dominant or long lasting, when compared to western Europe. Instead, several groups occupying smaller geographical areas, including Szakálhát and Esztár, appear to have existed within the same regions and time-period as the eastern LBK. These smaller groups are most likely to have been the founding populations of the well-known Late Neolithic tell societies. In this presentation, we introduce a new project – South Békés Landscapes – located in the archaeological under-explored region of the northern Maros fan in Békés County, Hungary. One of our research goals

7 is to understand the relationship between Szakálhát and Alföld LBK communities, and the processes by which conflicting traditions, ideas, and practices merged or melted away. Furthermore, we want to understand the prehistoric human-environmental interactions that contributed to the rise of tell-living. Our approach integrates multidisciplinary field surveys, remote sensing, and geoarchaeology with heterogeneous contributions by local collectors, rescue excavations, and legacy data from local museums. Still in its early stages, our project has produced new data, which we present along with legacy data to make sense of the South Békés landscape.

## 7 SOCIAL TRANSFORMATIONS IN THE LIMINAL AREAS. A MULTIDISCIPLINARY VIEW FROM IDJOŠ GRADIŠTE SITE IN THE NEOLITHIC

**Abstract author(s):** Maric, Miroslav (Balkanološki Institut Srpske Akademije Nauka i Umetnosti. Beograd) - Mirković Marić, Neda (Međupoštinski zavod za zaštitu spomenika kulture Subotica) - Bulatović, Jelena (Laboratorija za Bioarheologiju Filozofski Fakultet Univerziteta u Beogradu) - Marković, Nemanja (Arheološki institut, Beograd) - Amicone, Silvia (Competence Center Archaeometry-Baden Württemberg, University of Tübingen; Institute of Archaeology, University College London)

**Abstract format:** Oral

Idjoš Gradište site, located in Serbian Banat is the subject of a multidisciplinary archaeological research since 2014, focusing on formation and transformation of human societies between the Neolithic and Late Bronze Age, human landscape interactions, local area networks, communications and trade and exchange in a liminal area constantly awashed by influences of major traditions originating both of the Balkans and the Carpathian basin.

The site with several settlement horizons, occupied between the late sixt millenium and the first millenium BC is a large area of diverse traces of human activities, illustrating its varying use through time.

In our efforts to elucidate the origins, development and transformations of local population through time, a multidisciplinary approach to material culture remains, Bayesian chronological dating of events and scientific analysis of period proxy data is crucial.

We present the current state of research on the Neolithic settlement after five seasons and propose directions for future activities.

## 8 RAKING OVER THE ASHES: INTERDISCIPLINARY STUDIES FOR ASHMOUNDS BELONGING TO NOUA CULTURE (LATE BRONZE AGE)

**Abstract author(s):** Brasoveanu, Casandra - Asăndulesei, Andrei - Tencariu, Felix-Adrian (Arheoinvest Research Centre, Science Department, Institute of Interdisciplinary Research, Alexandru Ioan Cuza University of Iasi) - Brunchi, Radu-Alexandru (Doctoral School, Faculty of History, University Alexandru Ioan Cuza of Iasi) - Danu, Mihaela (Faculty of Biology, Alexandru Ioan Cuza University of Iasi) - Pîrnău, Radu Gabriel (Geography Department, Romanian Academy, Iași Branch)

**Abstract format:** Oral

Romanian Late Bronze Age, although very rich in archaeological discoveries, still remains unknown and misunderstood, because the vast majority of archaeological research has consisted of conducting field research or small surveys. Most of the data known so far were obtained by accident, in the context of the systematic research of settlements specific to other prehistoric periods.

During this time frame, a large part of the territory of today's Romania was occupied by Noua culture communities. The main characteristic of their settlements is the presence of so-called ashmounds. The little research undertaken that focused on their investigation, concluded that the remains are burned dwellings. Contrary to this hypothesis, recent research has shown that in the composition of these gray spots there is no ash. Also, the results obtained from the so far conducted magnetometric research, show no thermoremanent contrast generated by the ashmound. This confirms that the composition cannot belong to burned dwellings. Recently, these structures started to be seen as possible household pits, whose content has led to changes in soil color, thus sparking new controversies. The use of geophysical methods (GPR, magnetometry, electrical resistivity), together with pedological and archaeobotanical analyzes, for several case studies from NE Romania (an important area of concentration of settlements of this type) meets these concerns and seeks to find the answer regarding the ashmounds content, the planimetry of the settlements (some of the excavations suggest that the dwellings could have been placed between the ashmounds; the usage of geophysical methods will be able to confirm or invalidate such theories) and the human-environment relationship. The case studies were chosen from Jijia river basin, where 336 such settlements were identified. In conclusion, we believe that the interdisciplinary investigations of Noua sites, using modern research methods, can complete the existing information and can help to better understand these communities.

## 9 MODELLING THE SETTLEMENT SYSTEM OF LATE 6TH MILLENNIUM CAL BC SOUTHERN TRANSDANUBIA: OPPORTUNITIES AND LIMITATIONS

**Abstract author(s):** Oross, Krisztián (Institute of Archaeology, RCH, Eötvös Loránd Research Network, Centre of Excellence of the Hungarian Academy of Sciences, Budapest) - Gortva, Gergely (Archaeological Heritage Protection Directorate, Hungarian National Museum, Budapest) - Jakucs, János (Institute of Archaeology, RCH, Eötvös Loránd Research Network, Centre of Excellence of the Hungarian Academy of Sciences, Budapest) - Lyublyanovics, Kyra (Archaeolingua Foundation, Budapest) - Marton, Tibor (Institute of Archaeology, RCH, Eötvös Loránd Research Network, Centre of Excellence of the Hungarian Academy of Sciences, Budapest) - Serlegi, Gábor (Castle Headquarters Integrated Regional Development Centre, Budapest) - Vágvölgyi, Bence (Independent researcher)

**Abstract format:** Oral

The pivotal role of Neolithic Hungary as a connecting link between south-east and central Europe has long been recognized in the research of Prehistory. Recent large-scale excavations in southern Transdanubia and the following site-based studies of late 6th millennium cal BC settlements reveal a constant alteration and recombination of material culture, the elements of which have often been attributed to clearly separate entities. Series of AMS radiocarbon dates and their formal modelling provide a firm basis for comprehensive chronologies on various scales, even beyond detailed site biographies. Although hundreds of sites had been known before the intensive research activity of the past 25 years, no attempt was made to reconstruct the settlement network, except for a simple mapping of recorded sites.

The integration of datasets from previous fieldworks and fresh excavations, and the results of micro-regional surveys, facilitate a new level of modelling for the period between ca. 5350 and 4900 cal BC. This paper aims to present the regional settlement network independently of their associated material culture, as a coherent system of varyingly linked elements. We are seeking to answer whether any specific patterns are present, and if so, how do they correlate with other types of evidence derived from the archaeological record. The ongoing work also serves as a methodological experiment that intends to harmonize models of the settlement system with results of revolutionary, expanding research fields, e.g. absolute chronology and archaeogenetics. Further on, implications on the interpretation of the social organisation of early farming communities will also be discussed. A regional approach can demonstrate the dynamics of the settlement system, its potential for the Neolithisation process of central Europe, its further development and its relations towards both central Europe and more southerly areas in a long-term process that comprises almost half thousand years.

## 10 SMELTING POT OR SALAD BOWL? NEOLITHIC CENTER-PERIPHERY RELATIONS IN THE BALKANS AND THE CARPATHIAN BASIN

**Abstract author(s):** Hofmann, Robert (Kiel University, Institute of Pre- and Protohistoric Archaeology)

**Abstract format:** Oral

In a long-term historical perspective, in the Balkans and the Carpathian Basin we are dealing with 1) the chronologically and regionally differentiated introduction of producing economy in the Early Neolithic, 2) the subsequent consolidation of Neolithic societies in settlement systems characterized by increased regionalization and sedentariness in the Middle and Late Neolithic, and 3) the crisis and disintegration of this world at the transition to the Eneolithic. In the course of these processes, temporarily, large agglomerated villages emerged and regional differentiation took place between densely populated, particularly innovative core regions on the one hand and peripheral regions on the other. The dynamics of these processes can only be understood through the integrated analysis of different spatial scales, whereby micro-, meso- and macro-regional phenomena have to be distinguished. The paper attempts to outline center-periphery relations in the Carpathian Basin and adjacent areas under consideration of case studies in Okolište (Central Bosnia) and Bordoș (Serbia) and selected proxies such as site density, ceramic styles, settlement forms and metal objects. The Carpathian Basin proves to be a zone of intensive exchange and communication at the interface of different dynamic Neolithic 'world systems' beard by village-based pre-state societies with egalitarian ideologies.

## 11 NEW RESEARCH ON THE LATE NEOLITHIC TELL-SETTLEMENTS IN THE GREAT HUNGARIAN PLAIN (A CASE STUDY OF THE SZEGVÁR-TÜZKÖVES SITE)

**Abstract author(s):** Raczky, Pal - Füzesi, András (ELTE Inst. of Arch.Sciences) - Mesterházy, Gábor (Várkapitányság NZrt) - Szilágyi, Kata (Móra Ferenc Museum, Szeged) - Bánffy, Eszter - Rassmann, Knut (RGK DAI) - Stibrányi, Máté - Serlegi, Gábor - Klembala, Zsombor (Várkapitányság NZrt)

**Abstract format:** Oral

Before the 1990s, Hungarian archaeological research principally focused on the stratigraphy of the Neolithic tells of the Carpathian Basin. Later, there were efforts to set these tells within a broader South-East European context, specifically in terms of overall settlement patterns and their chronological dimensions. More recent

evidence would suggest that tells (Tisza-Herpály-Csőszhalom), circular enclosures (Lengyel) and single-layer settlements with a concentric layout (Cucuteni-Tripolye) embodied three different expressions of monumentality. It also became clear that these monumental "forms of expression" were enmeshed to create specific

architectural forms, multi-component sites in the Tisza region at the turn of the fifth and the sixth millennium BC.

Taking the above as our springboard, we launched a new multidisciplinary research project (ELTE, RGK), whose goal is the study of the iconic Neolithic tell settlements in this region. One of the first, perhaps symbolic, results of this work was achieved at the Szegvár-Tűzköves site, a since long known settlement of the Tisza culture where the clay figurine known as the Sickie God was found. Formerly, little more was known about the whole settlement than that it extended over 11 ha and that it had been completely destroyed. Yet, in 2020, an extensive magnetometer and experimental GPR survey was conducted at the site. As it turned out, the settlement covered nearly 31 ha, and we identified structured units of burnt houses ringed by an enclosure of multiple circular ditches. We were also able to determine the exact location of the earlier excavation trenches within the spatial context of the settlement.

A MINIMALLY INVASIVE AND MULTISCALAR APPROACH TO THE INVESTIGATION OF TELL SETTLEMENTS USING THE EXAMPLE OF THE BAPSKA SITE

Abstract author(s): Scholz, Roman (RGK - Romano-Germanic Commission DAI)

Abstract format: Oral

The Romance-Germanic Commission has been investigating the settlement landscape around the Bapska site since 2013, together with the University of Zagreb. This tell in the very east of Croatia is currently considered the westernmost known tell settlement of the late Neolithic. The stratigraphic sequence includes layers of the Starčevo, Vinča and Sopot cultures. Thus, the Tell, with a total thickness of approx. 4.5m, represents an important cultural archive that has been extensively investigated over the past few years using geophysical prospecting methods, intensive drill exploration, excavations and remote sensing operations. In addition, the existing satellite sites in the vicinity were included in the work. The presentation is intended to show the field archaeological methods that are to be used in the context of our entire research project. One of the overarching project objectives is to investigate the differences in the settlement landscapes. We concentrate on the tension between centrality and decentralization, on patterns of settlement and population sizes, on settlement-internal and regional spatial planning, subsistence strategies, forms of social organization and the development of regional patterns of house architecture and material culture. We examine the changes on a graduated scale. It is the level of the settlements, the surrounding micro-regions and, at the top level, it is the supra-regional exchange networks. The work in Bapska should provide some of the basic data to answer these research questions.

EARLY NEOLITHIC LITHIC RAW MATERIALS – EVIDENCE OF TRADE OR DIRECT ACQUISITION?

Abstract author(s): Sommer, Ulrike (Institute of archaeology, UCL)

Abstract format: Oral

The northern edge of the Carpathian Basin was a contact zone between incoming Neolithic and Mesolithic populations during the late Starčevo-Körös-Criş culture (SKC). A-DNA analyses show only a small genetic input by groups identified with hunter-gatherers in this time period, but, lacking formal cemeteries, burials tend to be quite rare. However, the economy in this area has a much larger hunting component that the core areas of SKC. In Tășnad-Sere (Romania), almost 47% of the animal bones derive from wild species, an uncharacteristically high percentage also found in several other sites of the period in NE Hungary.

Most of the raw materials for chipped stone tools come from sources at the rim or wholly outside the Carpathian Basin, which is no surprise given the predominantly alluvial soils of the former Pannonian sea. While the Blond Balkanic flint from the pre-Balkanic platform was already used in the earliest Neolithic of SE-Europe and probably marks the maintenance of links to the “old homeland”, the supply with obsidian and Wolhynian flint is often attributed to a contact with local populations, which may have paved the way for the Neolithisation of these areas during the LBK/ABK. This would indicate trade as a primary factor in establishing and strengthening contacts between different groups, a mechanism popular in both traditional and processional models of culture change. This narrative ignores, however, the limited mobility of Mesolithic groups as reflected in lithic resource spectra.

In my contribution, I am going to discuss alternative mechanisms of raw material procurement and the relation between SKC- and local populations.

THE IMPLICIT ASSUMPTION OF STONE TOOL DIVERSITY PATTERNS: EXPLORING ECONOMIC, SOCIAL AND RITUAL VALUATION PROCESSES OF LITHIC MATERIALS

Abstract author(s): Szilagyí, Kata (Mora Ferenc Museum)

Abstract format: Oral

This paper investigates in what way the quantity of raw material extraction, circulation, production and use of objects is connected to changes in the social systems (social complexity, inequality). To study this question, it is of crucial importance to understand the different dimensions of value of lithic artefacts. Value is a subjective concept which is determined by social interaction in real life contexts and thus variable and culture/society specific. Nevertheless, it is crucial to have an idea of how, in what ways and what kind of values and value-systems governed prehistoric societies.

Current accounts of the emergence of social inequality during the Late Neolithic and Chalcolithic period in Southeast Europe are as yet mostly based upon the presence of a few richly furnished burials, interpreted as expressions of individual social status and thus social inequality of the communities in question. However, the economic basis of this potential process of social stratification

CHALLENGING TIMES - CULTURES, GROUPS AND POTTERY STYLES IN EASTERN CENTRAL EUROPE IN 4500-4000 CAL BC

Abstract author(s): Szilágyi, Márton (Eötvös Loránd University)

Abstract format: Oral

In comparison with other periods of the Neolithic and Copper Age of Central Europe, the second half of the 5th millennium cal BC is a little underrepresented in the archaeological research. This situation is due to several reasons. One of these is that the earlier and later periods are represented by large cultural units, such as the LBK, the SBK, the Lengyel-complex, the TRB and the Baden-complex. Therefore, these periods obtained more interest among scholars and were studied not only from a local, but also from a wide, macroregional perspective. Contrastingly, the period between 4500-4000 cal BC is characterised by several small cultural groups throughout the Carpathian Basin and its western surroundings.

As a result, this period is characterised by different archaeological cultures, groups and/or pottery styles. Although some theories describe this phenomenon as an „interaction sphere” in the Late Lengyel period, these groups are mostly still seen as diverse cultural entities defined by pottery styles. This image became fuzzier with a new series of AMS dates from different areas of the region, which resulted in the collapse of the typochronological system built up during the 20th century.

In contrast with this fragmented picture, we can see large macro-regional networks, through which not only objects but also ideas and technologies were spread (e.g. copper objects and metallurgy, stone raw materials and knapping technologies, etc.).

One of the many crucial points is to understand how pottery styles were used in this wide region, and how do certain elements of these styles overlap one another. Can we identify existing entities based on pottery, or is it a part of such a large network as other cultural elements? In this paper, the framework of a newly started project will be presented, which aims to reconsider the cultural relations of the mentioned period.

CONNECTIONS AND RELATIONS BETWEEN THE CULTURES FROM LATE COPPER AGE TO EARLY BRONZE AGE IN EASTERN CROATIA

Abstract author(s): Balen, Jacqueline (Archaeological museum in Zagreb) - Miloglav, Ina (Department of Archaeology, Faculty of Humanities and Social Sciences, University of Zagreb)

Abstract format: Oral

Based on the collected data, which includes 14C dates and analysis of the material, from the recent archaeological excavation in the area of Eastern Slavonia, the authors will present a more comprehensive picture of the transition from Late Copper Age to Early Bronze Age period, with special emphasis on late Vučedol and Vinkovci Culture settlements.

The period of the Late Copper Age in Eastern Croatia was marked by the Vučedol Culture, which by the settlement organization, specialized potters, increased metallurgic activities, and social stratification reflects the new upcoming era in the prehistory - the Bronze Age. In the same region, the Vinkovci culture replaced (or inherited) the Vučedol culture in the beginning of the Early Bronze Age. The question of the division of both cultures into several phases, and thus the meaning of typological-chronological analysis of the ceramic material, is additionally raised. It seems that the basic differences can be noticed in different geographical areas in the same date frame, which further indicates the natural shift of the population and the blending of older, existing and new cultural phenomena.

VRÁBLE IN CONTEXT: THE VARIABILITY OF BURIAL AND DEPOSITION PRACTICES IN NEOLITHIC SETTLEMENTS OF THE CARPATHIAN BASIN AND BEYOND

Abstract author(s): Furholt, Martin (University of Oslo) - Cheben, Ivan (Slovakian Academy of Sciences Nitra)

Abstract format: Oral

The deposition of human bodies and body parts in and beside enclosure ditches is a phenomenon most prominently discussed in the context of LBK sites such as Herxheim or Asparn-Schletz, which date to the late 6th millennium BC. The LBK and Želiezovce settlement site of Vráble, Slovakia, provides a new, striking example. Comparable phenomena have however been discovered in several settlements of other archaeological affiliations and seem to represent an overall common theme, which could tentatively be characterized as circling around a symbolic marking of settlement space. However, the details of how human bodies are treated vary greatly from site to site, and they range from the deposit of cremated bones, to single bones or limbs, to the deposition of body parts and headless individuals. Other cases show traces of extensive violence, which have traditionally been interpreted in terms of

18 warfare, torture or capital punishment. In this paper, we will discuss different frameworks of interpretations, from the more profane ones mentioned to those emphasizing ritual or magic, to make sense of this diverse and yet similar set of practices.

18 TRANSMISSIONS OF THE MIDDLE COPPER AGE PATTERNS FROM THE CARPATHIAN BASIN TO LESSER POLAND AND THEIR LOCAL ADAPTATIONS

**Abstract author(s):** Wilk, Stanislaw (Jagiellonian University in Krakow, Institute of Archaeology; The Karkonosze Museum in Jelenia Góra) - Nowak, Marek (Jagiellonian University in Krakow, Institute of Archaeology)

**Abstract format:** Oral

Societies of the Early and Middle Copper Age in the Carpathian Basin constituted an exceptionally important civilization centre, strongly influencing other areas of the eastern part of Central Europe. Processes of reception of these cultural patterns by peripheral communities are still relatively poorly recognized. This applies i.a. to Lesser Poland. Between 4100-4000 BC there appeared in this territory communities which assimilated new, southern patterns of the Copper Age. Archaeologically, they are reflected by the Lublin-Volhynian culture and the Wyciąże-Złotniki group. In recent years quite a lot of new data connected with these units have been acquired, which refer to burial rite, copper artefacts, absolute chronology, territorial distribution, and cultural taxonomy. These data demonstrate that Eneolithic trends in Lesser Poland emerged as a result of selective cultural transmission and adaptation, donor of which were late Bodrogkeresztúr culture, Hunyadihalom culture, as well as the Ludanice group. The possibility to explain in detail the reception mechanisms, particularly from the social and ideological perspective, have been provided i.a. by discovery of a cemetery in Książnice. In particular, attention should be paid to the changes in the social structure related to 1) the “sepulchral” ideology, strongly distinguishing sacrum and profanum, 2) the elitism of a part of burials, 3) the strong gender differentiation of grave goods and position of the deceased. In conclusion we will argue that the Lublin-Volhynian culture and the Wyciąże-Złotniki group are to a large extent a reflection of privileged groups that achieved their status by controlling trade and cultural interactions between the areas north and south of the Carpathians in the period ca. 4050/4000-3700 BC. The presentation is based on results of the projects financed by the National Science Centre of Poland, nos. 2016/23/B/HS3/00387 and 2017/25/N/HS3/01140.

19 STARČEVO – KÖRÖS – CRIŞ REGIONAL AND MACRO-REGIONAL PALAEODEMOGRAPHY

**Abstract author(s):** Blagojevic, Tamara (University of Novi Sad, Biosense Institute) - Porčić, Marko (University of Belgrade, Faculty of Philosophy, Department of Archaeology) - Stefanović, Sofija (University of Belgrade, Faculty of Philosophy, Department of Archaeology; University of Novi Sad, Biosense Institute)

**Abstract format:** Oral

The Starčevo – Körös – Criş cultural complex covered a vast geographical region, chronologically spanning from ~6250 cal BC until ~5300 cal BC. Its importance lies in being one of the first Early Neolithic manifestations in this part of Europe, hence crucial for the understanding of its spread further to the rest of Europe. Changes in settlement patterns, material culture, and economy through time have been studied so far. The demographic processes that could have influenced the rate and the speed of the spread have been addressed for particular regions only. In this paper we present the results of the population dynamics reconstruction on the regional and macro-regional level, using the summed calibrated radiocarbon probability distributions method (SCPD). Regions are defined as follows: 1. Western Romania; 2. Southern Serbia; 3. Central Serbia; 4. Vojvodina; 5. Southern Hungary; 6. Eastern and northern Bosnia and Herzegovina; 7. Eastern and northern Croatia. The two defined macro-regions are: 1. Central Balkans (covering the southern and central Serbia); and 2. Pannonia (covering western Romania, southern Hungary, Vojvodina in Serbia, and eastern and northern Croatia).

20 LOCAL COMMUNITIES AND LARGE SCALE MOVEMENT OF POPULATION IN THE CARPATHIAN BASIN: NEW PERSPECTIVES ON NEOLITHIC MOBILITY USING ISOTOPE ANALYSES

**Abstract author(s):** Depaermentier, Margaux (Department of Prehistoric, Early Historic, and Provincial Roman Archaeology, Vin-donissa Professur, University of Basel) - Kempf, Michael (Department of Archaeology and Museology, Masaryk University, Brno; Institute of Environmental Social Science and Geography, University of Freiburg) - Bánffy, Eszter (German Archaeological Institute, Roman Germanic Commission) - Alt, Kurt (Center of Natural and Cultural Human History, Danube Private University; Integra-tive Prehistory and Archaeological Science, University of Basel)

**Abstract format:** Oral

Population movements on different geographical, temporal and demographic scales during the Neolithic period have long been im-plied by the study of archaeological material. One of the most important scenarios being that groups from the “Starčevo-Körös-Criş” complex – which was widespread in the northern Balkans during the Early Neolithic – moved in two parallel waves to the east and west of the Carpathian Basin and brought with them the premises of neolithisation in present-day Hungary. Nevertheless, spread of material culture can still be interpreted in many ways, thus the use of additional and complementary methods such as the analyses of strontium and oxygen stable isotopes provides more accurate data and new perspectives for the study of human mobility. In this study, which is part of a DFG (German Research Foundation) research project entitled “Population history of the Carpathian Basin in the Neolithic Age and its influence on settlement in Central Europe” (Al 287/10-1), 53 Hungarian Neolithic sites were selected for strontium and oxygen stable isotope analyses within a chronological framework spanning from the Starčevo to the Balaton-Lásinja cultures in Transdanubia and from the Körös to the Tiszapolgár cultural groups in the Great Hungarian Plain (Alföld). Based on these

isotope analyses and on their consideration at the different scales from the site to the supra-regional level, not only the main stages of neolithisation process but also small-scale mobility was investigated. Sampling more than one tooth per individual also provided insight into the stages of a person’s youth and thus allowed the observation of further mobility patterns at the individual level.

21 BORDERS? - WHICH BORDERS?

**Abstract author(s):** Schwenzer, Gerit (no affiliation)

**Abstract format:** Oral

The modern day border triangle of Austria, Hungary and Slovakia divides an area so rich in archaeology, history and culture which once was so tightly connected. At the far western area of the Carpathian basin a lot of cultural movement happened at the end of the late Iron Age and the beginning of Romanization. In the rough time frame of 150 years four different cultural groups moved in these parts, connected and seperated again in the one way or the other. Networks of trade were created which survived into Roman times and were adapted. Borders were more flexibly interpreted than at present day. This paper shall shed some light on the inter-actions of these cultures at the end of the late Iron Age and the brink of Romanization. A selection of important sites and some key points of the networks as well as the mutual impact of the peoples in this region shall be presented and discussed.

334 HUMAN-ENVIRONMENTAL NETWORKS IN HEALING CULTS, RURAL SANCTUARIES AND SACRED GROVES BETWEEN INTERSECTIONALITY AND transcultural NEGOTIATION

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Da Vela, Raffaella (SFB1070 ResourceCultures; Universität Tübingen, Institut für Klassische Archäologie) - Krämer, Robinson (Universität Rostock, Heinrich Schliemann-Institut für Altertumswissenschaften) - Blasetti-Fantauzzi, Chiara (Freie Universität Berlin) - De Vincenzo, Salvatore (Università della Tuscia, Dipartimento DISUCOM)

**Format:** Regular session

Cult places in geographically exceptional positions, such as in caves, on mountain tops, or near springs, played supra regionally sig-nificant roles in different geographic and chronological contexts. Serving as important meeting points of local communities, these sanctuaries became transcultural hubs for shared economic spaces and resource landscapes. These cult places can be understood as human-environmental networks, where human and non-human actors were deeply entangled. Ritual experiences and cult(ural) practices built a common platform, allowing to overcome social differences and to negotiate personal identities. Which was the role of the non-human agency in these cult places? Did landscapes have a proactive role in sharing cult practices and in connecting communities?

Food for thought:

- Agency of Landscapes

Communities shaped sacred landscapes on their own socio-economic and religious needs. However, the environment also influ-enced the choice and the characteristics of cults. What role did landscape features play in the selection of sites for healing cults? Are their implications similar or did they variate in different sociocultural contexts?

- Intersectionality

The focus of these cults on non-human agency allowed worshipers to overcome social conventions and to create new temporarily shared reference values. Were these cults stages for the negotiation of personal identities? Did cult practices construct new or extraordinary identities?

- Sacralization of Resources

Resources, such as salt in pastoralism, wine in the Mediterranean, or rice in agricultural regions of India, became important elements in the semantics of cult. Did the sacralization of resources create spaces of negotiation between communities? Were healing cults bottlenecks in specific resource networks?

- Political Economy

Cult places could serve as institutions for the storage, control and redistribution of goods. Did social groups manipulate parts of the political economy through access to ritual activities, norms, values and beliefs? Can collective feasts at cult places be interpreted as expressions of socio-political power?

ABSTRACTS:

1 MOUNTAINS OF MEMORY TRIANGULATING LANDSCAPE, CULT AND REGIONAL IDENTITY THROUGH ZEUS

**Abstract author(s):** Woznura, Adam - Williamson, Christina (University of Groningen)

**Abstract format:** Oral

Mountains hold a special place in the human mind, possessing a deep ontology unlike any other natural feature. Social geographer Yi-Fi Tuan states: ‘modern nations like to think that a high peak, if not the world’s highest, lies within their border’ (1977: 40). This was no less the case in the pre-modern world, although claims to such heights were typically framed in terms of divine power. Besides

- 2

political power, mountains can also anchor a special sense of place, intersecting the spheres of the human and the divine. This paper aims to understand the triangular relation between mountains, religion, and regional identity in the ancient world by focusing on three different peak sanctuaries of Zeus: Zeus Lykaïos on Mount Lykaion, Zeus Akraios on Mount Pelion, and Zeus Stratios on a mountain plateau by Amaseia. Each of these peak sanctuaries are assessed for their role in providing a regional focus within emerging political landscapes.

The analysis focuses on the physical mountain, the narratives associated with it, the visuality through viewshed analyses, and the role of ritual and festival as the cult becomes absorbed by a nearby city. Through our analysis, incorporating material evidence such as epigraphy and numismatics, we show that visual prominence was not always their main asset. Local myth and legend played a part in foregrounding these cults in the surrounding regions, helping the mountains to acquire a symbolic and political importance over time.

We conclude by suggesting that these mountain sanctuaries of Zeus provided a focus of social memory, were storied places that became important in the political landscape, and were places claimed by nearby cities to legitimise their own place in the landscape, thereby creating a sense of region.

**MARITIME NETWORK MODELLING FOR THE ANALYSIS OF CULT TRANSMISSION IN THE SARONIKOS KOLPOS (6C-1C BCE)**

**Abstract author(s):** Delacruz, Michael (Oxford University; Newcastle University)

**Abstract format:** Oral

This paper examines the phenomenon of cult transmission in the Saronic Gulf during classical antiquity in specific relation to its maritime context and the utility of alternative methods of network analyses to illuminate the linkages between cult, economic relations and political instrumentality. Observations from the provisional application of proximal point analysis (PPA), social network analysis (SNA), and network optimization to a limited (but real-world) data set are discussed. The transportation of the healing cult of Asklepios (through its embodiment in the sacred snake) by Telemachos Acharneas in 419 BCE from the Asklepion in Epidaurós to the southern slopes of the Acropolis is the example par excellence during this period of the importation of an alien cult in order to secure both religious (as a palliative measure in the wake of plague) and geopolitical (to secure port access on the southern Peloponnese) objectives. Indeed, the locations at both Epidaurós and Athens, their orientation, and visual affordance reflect an intertwined relationship between these sanctuaries and the broader environmental setting of the Saronic that in the early years of the Peloponnesian War would become a region of increasingly critical importance. The location of other sanctuaries throughout the Gulf islandscape, such as the Sanctuary of Dionysos on Salamis (which based on archaeological evidence appears to be linked to rites of fertility) or the Asklepion at Troezen reveal a similar territorial consciousness encompassing both a sense of belonging and interconnectedness with the maritime communities around them. Likewise, the proximity of points-of-embarkation and loci of economic activity/production to these and other cult sites in the region indicate a close relationship between specific cult practices and the wider system of socio-economic relations. As a promising set of tools, the application of network modelling, including PPA, SNA, and flow/path optimization, can provide quantifiable affirmation of these relationships.

**OF SACRED LAKES, SPRINGS AND CAVES: CULT PLACES AND RESOURCECULTURES IN THE NORTHERN APENNINES DURING THE IRON AGE**

**Abstract author(s):** Da Vela, Raffaella (Post-Doc Researcher at the SFB1070 RessourcenKulturen University of Tübingen)

**Abstract format:** Oral

Sacred groves and lakes, as well as holy caves where healing cults performed their activities, were central hubs in the sacred landscape of the northern Apennines. At the crossroads of transhumance and commercial routes, and at the meeting points of different geo-cultural areas, these cult places in the mountains were difficult to reach, hidden and secluded without any outlook over the plains. Indeed, the secret paths to these places required a guide, whose knowledge of their location was probably individually transmitted. These difficulties of access can be seen as adding value to these places. Worshippers had to experience a difficult journey and learn the path, in order to finally reach a place where they were surrounded by natural elements and thus would become background figures in the divine 'show'. These evocative natural locations were both stage and active agent in the encounters between humans and gods. At the same time, these places attracted worshippers from different neighbouring geo-cultural regions, who left material signs of their presence, including objects that they took away as physical remembrances of these encounters. These objects have been found on the plains on both sides of the Apennine mountains in different cult contexts, and indicate shared cult practices, as well as a geographic spread of religious knowledge and meaning attached to objects. The present contribution aims to discuss the evocative power of these natural places and their value in shaping the evaluation processes of cult objects and rituals across the Etruscan Apennines during the Iron Age.

**HOLY WATERS AS PLACE OF ENCOUNTER AND NEGOTIATION IN PADANIAN ETRURIA: RECORDS FROM CASTELFRANCO EMILIA AND LAKE BRACCIANO OF MONTESE**

**Abstract author(s):** Neri, Diana (Comune di Castelfranco Emilia - Museo Civico Archeologico) - Campagnari, Sara (Ministero per i Beni e le Attività Culturali e per il Turismo)

**Abstract format:** Oral

Two important archaeological findings concerning the cult of waters occurred in the Panaro river valley, in the province of Modena. These waters have healthy attributes, such as those coming from salsobromoiodic springs, or those from resurgences, providing homeothermy and natural self-purification.

In Emilia-Romagna such natural phenomena are frequently connected with the cult of a goddess, protector of the feminine sphere. During the Roman Age her identity is Minerva, while in most cases she incorporates divinities related to the Etruscan, Celtic and Ligurian melting pot inhabiting the area at the time of Romanization. These places of worship are often located near communication routes, at least from the early Iron Age.

The worship area of Prato dei Monti is located near the soon to come via Emilia in Castelfranco Emilia, formerly Forum Gallorum. The area features many springs and is probably located near the Minerva worship area, quoted by Cassio Dione relating to the prodigia of the war of Mutina (43 b.C.). A border sanctuary exists near the Lake Bracciano of Montese, located in the mountain area. In spite of its marginal location, it bears a strong strategical position, along routes through the valleys. The area is a meeting point for different ethnic groups residing there at the eve of Romanization. These people were shepherds practicing transhumance along the valley thus contributing to important market places such as the Campi Macri. Both places offer various votive objects, dating from the 6th century to at least the 3rd century B.C., when the Celts occupy Emilia-Romagna. During the Roman age the Prato dei Monti area features solely cults of Italic matrix.

**THE AGENCY OF LANDSCAPES IN THE DEVELOPMENT OF CULTS IN REPUBLICAN CENTRAL APENNINE ITALY**

**Abstract author(s):** Blasetti Fantauzzi, Chiara (Freie Universität Berlin)

**Abstract format:** Oral

Religious space of the local communities of central Apennine Italy during the Republican period is often determined by the topographical framework and environment of sacred sites, underlining the importance of the topographical contextualisation of such sacred areas. They can be characterised by areas for open-air meetings that are marked by evidence of ritual practices, depositions and sometimes altars, or are linked to a specific natural setting, such as a cave. Between the 4th and 1st century BC there is a widespread distribution of healing (sanatio) cults, often associated with water, and cults connected to pastoralism. During the 2nd century BC some of those sanctuaries underwent a monumentalization process, while others slowly lost importance.

This paper focuses on the agency of landscape in the establishment and development of cults and sanctuaries in the Central Apennine area from the Roman colonization to the Roman Imperial period, with the latter covering an obvious cultural break. By focusing on an area that is specifically defined in time and character, both local characteristics and those shared with the rest of Republican Central Italy can be highlighted from synchronic and diachronic perspectives. Our interpretation of the tempo-spatial patterns acknowledges not only cultural implications but also the significance of topographical distributions and territorial functions of these cults.

**LANDSCAPE AND CHTHONIC CULTS IN REPUBLICAN CENTRAL ITALY**

**Abstract author(s):** Calapà, Annalisa (Ludwig-Maximilians-Universität München)

**Abstract format:** Oral

The correlation between natural environment and chthonic cults is often especially striking. Cult places for chthonic deities in ancient Italy could be situated in places with exceptional landscape features, such as volcanic crater lakes (the Avernus being the most prominent example) or caves from which suffocating vapours arose, as in the sanctuary of Mephitis at Ampsanctus. A closer examination of our evidence shows that other landscape elements were associated with underworld gods: dei inferi could be worshipped in sanctuaries located by lakes or rivers, on islands, in thick forests (silvae) or smaller groves, or by the sea. This paper aims to analyze the circumstances that could lead to the formation of a chthonic cult in a specific environment; this can help to assess how, conversely, the environment could be shaped to create cult places for underworld gods in suburban and rural locations. The analysis presented in this paper, which especially focuses on Etruria, Latium and Campania, can also contribute to outline and to understand other relevant issues. Firstly, many cult places for chthonic deities, because of their particular features, seem to have been characterized as liminal zones and contact zones, which could serve as transcultural meeting places and connect people from different communities with each other. The examination of these peculiar aspects could shed some light on some Etruscan sanctuaries located in border areas by lakes or rivers, which have been mostly considered by researchers as water-related 'healing sanctuaries'. Secondly, the paper will also discuss the evidence suggesting that some cult places for chthonic deities were of special significance for marginal social groups, such as freedmen or slaves.

7

CULTS, PLACES, ANATOMICALS. SO-CALLED HEALING SANCTUARIES REVISITED. NEW INSIGHT ON TRADITIONS, INTERRELATIONS AND ALIGNMENTS

**Abstract author(s):** Boecker, Velia (Deutsches Archäologisches Institut)

**Abstract format:** Oral

After tackling the question which cult sites we do consider as healing cults – i.e. which kind of topography, architecture, written sources, venerated deities and specific finds provide the basis to assume a sanctuary was specialised in healing – the presentation will focus on the phenomenon of anatomical votives in sanctuaries of Latium (Italy) dedicated in the 4th to 1st cent. BC. These votives were hitherto understood as indicators for so-called healing cults. The archaeological and historical contexts though, e.g. the associated finds as well as the topographic position of the sites and their traditions, have hardly been focused yet. Featuring a holistic and contextualising approach the lecture will present the analysis of more than 100 sites in Latium with a total of over 15.000 anatomical votives regarding their connection to environmental parameters as springs, lakes, mountain tops, caves and connections to roads and settlements. Quantitative and gender-specific analyses are also taken into account. Based on this data the so-called healing cults of Latium can be divided into two main groups which differ from their location, the composition of the dedicated votives, the venerated deities and probably the dedicants.

These two groups presumably root in local cult traditions and were spread by entangled communities with shared or similar religious conceptions. Given that, anatomical votives can be understood as part of an indigenous identity within a broader network of cultural exchange. Very likely the anatomical votives should not be seen as objects with a prescribed meaning in a static cultic frame but as multivalent offerings in a dynamic frame of reference.

Contributing this new insight on tradition, interrelation and alignment may broaden the session’s perspective on healing cults and add a significant benefit to the discussion.

8

CULTS AND THE COLONIES – EXTRA-URBAN SANCTUARIES IN COLONIAL TERRITORY IN REPUBLICAN CENTRAL ITALY

**Abstract author(s):** Bolder-Boos, Marion (Johannes Gutenberg-Universität Mainz, Arbeitsbereich Klassische Archäologie)

**Abstract format:** Oral

A significant number of extra-urban sanctuaries in Republican Italy were located in the hinterland of Latin or Roman colonies. Many of those cult sites, however, were not founded by the colonists but originated in pre-Roman times and thus went back to indigenous cults. While the Romans often changed certain aspects of these indigenous cults, the cult sites themselves were often continued and could, like the sanctuary of Marica a few kilometres west of Minturnae at the mouth of the Liris River, obtain a quite prominent position within the colonial pantheon. In other cases, however, such extra-urban cult places were abandoned and subsequently forgotten. Only rarely did the colonists destroy a pre-Roman sanctuary intentionally.

Various factors could have affected the continuation or abandonment of an extra-urban sanctuary: its importance for the indigenous population, where it could hold the danger of becoming a rallying place for those resisting Roman occupation; the nature of the cult and its compatibility with Roman religious ideas; the perceived sanctity of the place. The latter aspect leads to the question which role the natural landscape played in which a cult place was situated and whether the location in a geographically exceptional position made a difference. Did certain natural features – such as springs, rivers or grottoes – favour the continuation of a cult site in a colonial setting, even though it was created by an indigenous population? And how was identity negotiated in such a place?

The paper seeks to address these issues by giving an overview of the known extra-urban sanctuaries on colonial territory in Central Italy and their environmental setting, discussing the diverse landscape features as well as aspects of cult and – where possible – the deity (or deities) worshipped there.

9

HEALING CULTS IN SOUTHERN ETRURIA DURING THE ROMAN PERIOD

**Abstract author(s):** De Vincenzo, Salvatore (Università degli Studi della Toscana, Viterbo)

**Abstract format:** Oral

Sacred contexts related to healing (sanatio) are particularly widespread in the whole of Etruria during the Late Republican and Early Imperial period. This paper will analyse the sacred landscape of Etruria between the 4th century BC and the 1st century AD, with special focus on healing cults in relation to agrarian and chthonic cults. The aim is to understand the topographical features as well as the political, commercial and social motivations that were the driving force for the establishment of these cults. A thorough analysis of the votive material by comparing stylistic and stratigraphic data led to a more precise dating of the sites, indicating that the sacred areas that were thought to have been abandoned in the 2nd century BC were in use until at least the Early Imperial Period. In this light, prominent sacred contexts in urban and non-urban areas, especially Veio, Tarquinia, Volsinii Novi and Vulci, will be redefined.

10

REPRESENTATION AND IDENTITY NEGOTIATION IN THE EASTERN IBERIAN PENINSULA. SACRED LANDSCAPES AS SOCIO-POLITICAL RESOURCES IN HISPANIA DURING THE ROMAN-REPUBLICAN PERIOD

**Abstract author(s):** Kramer, Robinson (University of Rostock)

**Abstract format:** Oral

In the 3rd–1st centuries BCE, Iberian societies in eastern Hispania faced the presence of Carthage and Greeks and eventually Roman conquest. In particular, the Roman expansion in the Iberian Peninsula led to dramatic changes in social structure, resource management, language and writing, and settlement structure, which often resulted in the transformation from oppida to urban structures.

In this contribution, I examine how these changes were manifested in the religious field and how different actors, especially Iberians and Romans, represented themselves and expressed or negotiated identities in this context. These socio-religious practices can be traced in sacred architecture and modifications of buildings, votive material (e. g. pottery, bronze figurines and statues) and the imagery in ritual contexts. The study of these materials helps to understand the various strategies of representation and the extent to which sacred landscapes could serve as political resources and spaces of social negotiation during the Roman-Republican period.”

11

TRACES OF THE ROMAN SANCTUARIES ALONG THE KRKA RIVER

**Abstract author(s):** Jadric-Kucan, Ivana (University of Zadar, Department of Archaeology) - Sokcevic Purusic, Anamaria (Archaeological collection Burnum, National Park “Krka”)

**Abstract format:** Oral

In the Roman times, the Krka River was a very important geostrategic point which, with its steep deep canyon, was a natural barrier that was impossible to cross. That was one of the main reasons for founding the Roman legionary camp Burnum in its immediate vicinity. Only a few convenient natural positions due to the combination of travertine barriers and valleys allowed crossing over it and contact between the two shores, which were then used by the Romans, as main roads. One of them is the crossing at the Čavlinov buk position, in the upper part of the Krka river. Numerous archeological finds were found here, including inscriptions of the gods Neptune and Mercury ?, fragments of architecture such as a stone architrave decorated with relief depictions of aquatic animals, pillars and capitals indicate that they probably belonged to a significant sanctuary associated with the river and crossing. On the middle course of the Krka river, at the crossing near Roški slap, a dedicatory inscription to the Liburnian goddess Latri was found, erected by the Praetorian evocate. All this shows how these crossings played an important role in the spiritual life of the travelers and the merchants who passed through it, but also of the soldiers who lived in its immediate vicinity.

12

GODS OF PLACES OR OF PEOPLE? A STUDY OF RURAL CULT SITES AT THE EDGE OF THE ROMAN EMPIRE

**Abstract author(s):** Mazzilli, Francesca (University of Bergen)

**Abstract format:** Oral

A recent conference, Naming and Mapping the gods in the Ancient Mediterranean. Spaces, Mobilities, Imaginaries (Toulouse, 10th-12th February 2021), investigated the intersection between the divine and space and between the spaces and designations of the gods. From this symposium it has emerged the importance of spaces and human agents in the formation of religion in Antiquity from ritual practices to naming deities.

This paper aims to discuss to what extent the environment and the social network influenced:

- the erection of rural cult sites and their gods in a specific place, like hilltops;
- the function of these cult sites, from hubs of village community to sacred places because of their location near “healing” and “divine” natural resources.

An analytical approach of the study of rural cult sites in regional case studies at the edge of the Roman Empire (Lusitania, roughly Portugal, and the Hauran in the southern Syria) will be undertaken on two levels:

- Through the study of naming gods: from toponym to deities named after an individual;
- Through spatial analysis: location of cult sites in relation to topography, water sources, and administrative infrastructure network of villages and cities.

A.

HONEY BEES AND HONEY: MYTHOLOGY, PROPHECY, AND HEALING

**Abstract author(s):** Zak, Claire (Texas A&M University)

**Abstract format:** Poster

Beekeeping occurred on Crete by the 1500s BCE. Coins of Militaea from this time depict Zeus on one side and bees on the reverse with an inscription reading “MELI” (honey). For the ancient Greeks, Crete was seen as the origin place of bees, since it was here that Rhea is said to have given birth to Zeus. On Crete, the future king of the gods was raised on honey and milk, thanks to Melissa, the daughter of the king of Crete, Melisseus. In myth, Melisseus was the first to sacrifice to the gods and Melissa becomes the first priestess to the Magna Mater (and in some versions of the story is turned into a bee herself). Priestesses and attendants to various deities continued to be called melissae after their mythological namesake. Associations with Zeus, Apollo, and Dionysus allowed a

prophetic aspect to be attributed to bees, which extended to the sacred landscapes of Mount Dicte, the oracle sanctuary at Delphi, the home of the Thriae prophetic nymphs at Mount Parnassos, and cemeteries.

The ancients believed that if one were to consume honey, they would interact with the divine, and adopt the characteristics attributed to bees. Poets and prophetic figures were often said to have been fed by bees during infancy. By ingesting honey, a person could be pure, chaste, holy, prophetic, or come into contact with the divine. Nectar was not only food for the gods, but also food of bees.

Because of bee’s proximity to the divine, honey also had a high sacrificial value and was used in funeral rites as offerings to the dead. Some believe that the bee embodies the soul of the dead and swarms of buzzing bees were the dead flying around on earth. Bees were chthonian creatures, connected to ideas of preservation and resurrection.

B. THE CULT OF NEPTUNE IN BURNUM

**Abstract author(s):** Jadric-Kucan, Ivana (University of Zadar, Department of Archaeology) - Sokcevic Purusic, Anamaria (Archaeological collection Burnum, National Park “Krka”)

**Abstract format:** Poster

In the upper course of the Krka River (Titius flumen) at the crossing Cavlinov buk, where in Roman times was a bridge that passed through it and the main road, a dedication to the god Neptune was found. During the past, construction works were carried out in this area, during which the remains of Roman architecture were found (parts of architraves with reliefs of amphibians, a fragment of a spiral pillar and a Corinthian capital) and it is possible that these are the remains of Neptune’s sanctuary. Furthermore, a monumental head of Neptune? originates from Burnum. The Krka River played an important role in the life of the surrounding population, both indigenous and later Roman, and it was precisely because of it that the Roman legionary camp Burnum was built there. Therefore, the worship of the deity of the sea and running waters was an important part of their spiritual life.

337 DECIPHERING TURNING POINTS IN HUMAN-ENVIRONMENTAL INTERACTION

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Feeser, Ingo (Institute for Pre- and Protohistoric Archaeology, Christian-Albrechts-University of Kiel) - Dreibrodt, Stefan (Institute for Ecosystem Research, Christian-Albrechts-University of Kiel) - Niebieszczański, Jakub (Faculty of Archaeology, Adam Mickiewicz University in Poznań) - Robin, Vincent (Interdisciplinary Laboratory for Continental Environments, CNRS, Lorraine University) - Wiethold, Julian (Institut national de recherches archéologiques préventives - Inrap, Direction régionale Grand Est Alsace - Champagne Ardenne - Lorraine Laboratoire archéobotanique)

**Format:** Regular session

This session offers the possibility to present new results and approaches of bio- and geoarchaeological research with the aim to identify turning points of human-environment interactions of the past and their reflection in the investigated archives. Of particular interest hereby are interdisciplinary approaches, which combine data from different spatial and/or temporal scales.

Investigations of plant remains (e.g. pollen, plant macro-remains, phytoliths, charcoal and wood), geochemical signatures of archaeological artefacts or sediments and soils are regularly and complementarily applied at and around archaeological sites. The results of such local scale studies generally allow an insight to economical activities and subsistence practices. However, in order to get an idea about their general importance and their related impact on the natural environment, they have to be evaluated in context of the (supra-) regional developments as derived from off-site and/or meta-level investigations. Although such a synthesis of palaeoenvironmental data on different temporal and spatial scales is a challenging task, considering the involved individual uncertainties and the increasing complexity, this is regarded to be crucial for describing patterns of ancient human-environmental relationships, including the identification of involved triggers, drivers and thresholds levels. In order to enable holistic reconstructions of human-environment interactions in past landscapes the results of the various disciplines need to be integrated into joint explanatory models. Of particular interest hereby is the identification of turning points of human environmental interaction, at which the qualitative relationship of human activity and their associated environmental impact changed.

Contributions providing new insights on landscape processes reflecting the natural environment’s responses to changed prehistoric and historic human activity (e.g. innovations, type of land use techniques) or natural variability (climate, natural disasters) which can be connected with evidence for changed economic activities and land use practices archaeological data on local, regional and supra-regional scale are welcome.

ABSTRACTS:

1 HUMAN-ENVIRONMENT INTERACTIONS IN THE BELGIAN DIJLE-DEMER CATCHMENT (800 BC-1000 AD) – AN INTERDISCIPLINARY APPROACH

**Abstract author(s):** van Zon, Marleen (Faculty of Arts, Centre for Archaeological Research of Landscapes, KU Leuven; Faculty of Sciences, Dept. Earth and Environmental Sciences, Division of Geography and Tourism, KU Leuven) - Vanmontfort, Bart (Faculty of Arts, Centre for Archaeological Research of Landscapes, KU Leuven) - Verstraeten, Gert - Broothaerts, Nils (Faculty of Sciences, Dept. Earth and Environmental Sciences, Division of Geography and Tourism, KU Leuven)

**Abstract format:** Oral

Floodplains are highly dynamic environments that have attracted humans throughout history. As such, they have not only been shaped by the interplay of geomorphological, ecological and hydrological processes. They have also been directly and indirectly impacted by human activity. It is in these parts of the landscape that we find ideal research areas to study and reconstruct transformations of human-environment interactions through space and time.

One such area, the Dijle-Demer catchment (Belgium), has been selected as the main point of focus of the Floodplainscapes-project. Prior research has identified human impact as a driving force, if not the driving force, of morphological and ecological change in floodplains. Its progression throughout the Middle and Late Holocene can be characterised as non-linear, ranging from rapid increases to periods of regeneration. How this relates to the human activities involved is the subject of ongoing research and will form the main topic of this presentation.

Archaeological and historical sources are studied and integrated on a large spatial and temporal scale. This facilitates integration with the available environmental studies. Set against a back-drop of climatological and socio-political developments taking place on a supra-regional scale, we aim to identify the complex set of factors that trigger changes in human-environment interactions throughout the Iron Age, Roman and Early Medieval Period. For now, major components are considered to be settlement patterns, agricultural practices and artisanal activities. At a later stage these will be studied in greater detail through several case studies, to come to a high-resolution understanding of the processes taking place on a local scale.

2 PREHISTORIC AND HISTORIC TURNING POINTS IN CENTRAL GREATER POLAND SEEN THROUGH GEOARCHAEOLOGICAL STUDY OF BRUSZCZEWO SETTLEMENT COMPLEX IN SAMICA VALLEY

**Abstract author(s):** Niebieszczanski, Jakub - Radke, Iwona - Kołaczek, Piotr - Rządziejewicz, Monika (Adam Mickiewicz University in Poznań)

**Abstract format:** Oral

In the area of central Greater Poland, one of the most well documented multi-cultural sites is that in Bruszczewo. The site is commonly known from its earliest phase of occupation, when the unique fortified settlement of the Unetice culture thrived there during the Early Bronze Age, however the presence of Neolithic activity was also documented. After abandonment of defensive site and a few hundred year of occupation hiatus, the Lusitan culture people established their ritual center during the Late Bronze Age and Early Iron Age. Afterwards, in a close vicinity, the Przeworsk culture people located their settlement, while the Early Medieval occupation phase was connected to the motte stronghold of the Slavic tribes. This long habitation history occurred in and around the middle part of the Samica Valley, which is believed to be a lake and marshland in the past.

This region witnessed major archaeological projects, which created a well-established cultural reconstruction. The Samica Valley was also a subject of initial geoarchaeological research oriented towards the recognition of general history of the lake development during the Bronze Age and up to the Early Medieval.

The following presentation shows first results of a new geoarchaeological study\* which aims to connect the already well-recognized cultural succession with the environmental history of Samica Valley and its transformation due to the fluctuating human impact. Several cores are being submitted in this study to a multiproxy palaeoenvironmental reconstruction, supported by a large series of AMS dating, in order to correlate the turning points in human development (changes in land-use, increased mobility, metallurgy) with changes recorded in natural archives of the Bruszczewo palaeolake and marshes.

\*The study “Living by the Lake(…)” is funded by the National Science Centre, Poland, grant no. 2019/33/B/HS3/00193.

3 ‘XEROS’ OR NOT? : THE XEROS RIVER VALLEY IN CYPRUS AND ITS HISTORY THROUGH THE AGES

**Abstract author(s):** Mylona, Pantelitsa - Vionis, Athanasios (University of Cyprus) - Devillers, Benoît (UMR5140: AMS-CNRS-Université de Montpellier 3)

**Abstract format:** Oral

The Xeros River (meaning ‘dry’ in Greek) is located on the south coast of Cyprus in the administrative district of Larnaca. The Settled and Sacred Landscapes of Cyprus (SeSaLaC) project of the University of Cyprus investigates human activity in the valley diachronically through intensive field survey. The project also employs the application of a geoarchaeological approach to shed light on the interactions between human societies and the natural environment, considering alluvial deposits as a suitable indicator of environmental and topographical changes. This paper (a) aims to present preliminary observations on the evolution of the valley through time and (b) attempts to examine how societies adapted to topographical changes due to the shifting of the Xeros riverbed. The

relevant results derive from field observations, radiocarbon dating of alluvial paleosols and laboratory analysis, such as XRF and magnetic susceptibility, which allow the establishment of a chronological framework of alluvial formation, the decryption of the alluvial dynamic and the evolution of the valley. Combined with the archaeological data of the field survey, we outline the evolution of settlement systems and movement through time.

4 **HOLOCENE GEOMORPHODYNAMICS OF THE TEKKEDERE VALLEY, PERGAMON MICRO-REGION (WEST TURKEY) AND THE INTERACTIONS BETWEEN HUMANS AND THE ENVIRONMENT**

**Abstract author(s):** Yang, Xun - Becker, Fabian (Freie Universität Berlin) - Knitter, Daniel (Christian-Albrechts-Universität zu Kiel) - Schütt, Brigitta (Freie Universität Berlin)

**Abstract format:** Oral

Sediments and archaeological remains are key archives in understanding human-environment interactions. Associated data on relief and local memories allow to identify potential triggers of changes in the interactions at local to regional scales. Integrating these quantitative and qualitative data, we evaluate the landscape development—especially the entanglement of settlement history and environmental dynamics—in the Tekkedere valley, a small mountainous drainage basin of the Aegean Region in Turkey. The valley lies in the micro-region of the ancient city Pergamon and has been continuously settled since Bronze Age. The settlements were occasionally relocated in the last three millennia.

Our main research aim is to explore how the growth of Pergamon and the rearrangement of settlement patterns in the micro-region between Hellenistic and Roman Imperial Period mark a changing point in human-environment interactions—on the local scale and on a meta level.

Results from geomorphological research in the Tekkedere valley imply that settlements from different periods were located at specific positions. Floodplain sediments of the receiving Bakırçay river are covered by and interfingered with Tekkedere alluvial fan sediments, indicating high flood events. Cycles of coarse and fine fan deposits reflect morphodynamic phases varying in intensity. Soil formations suggest periods of landscape stability, which alternate with intensified erosion indicated by colluvial sediments. First reconstructions of morphodynamics in the valley based on the sedimentological data are in agreement with the modified meta-analyses of 14C-ages from the micro-region. Phases of enhanced morphodynamics in the region can be linked to the increased anthropogenic pressures during the Hellenistic and Roman Imperial Period, which is contrary to findings from other regions in Anatolia. Additionally, an earthquake-triggered landslide was the main reason of the last settlement relocation according to information from locals. Our work widens the perspective that valley-scale settlement patterns may respond to socio-economic transformations and natural hazards.

5 **WHAT HAPPENED AFTER GÖBEKLI TEPE? HUMAN-ENVIRONMENTAL INTERACTIONS IN THE URFA REGION FROM A HISTORICO-CULTURAL AND NATURAL SCIENCE PERSPECTIVE**

**Abstract author(s):** Braun, Ricarda (Freie Universität Berlin) - Ögüt, Birgül (Deutsches Archäologisches Institut) - Lange, Matthias (Humboldt Universität Berlin) - Nykamp, Moritz (Freie Universität Berlin) - Knitter, Daniel (Christian-Albrechts-Universität zu Kiel) - Schütt, Brigitta (Freie Universität Berlin)

**Abstract format:** Oral

From a historico-cultural perspective the Urfa region in southeastern Turkey has a divers and dynamic history: The occupation of the region began at the latest in the early Neolithic, which is also the most studied period, with sites like Göbekli Tepe and Karahan Tepe as probably the best-known examples. Unjustly less known and researched, however, is the cultural history of the following periods. This is surprising, since at least from the Assyrian period onward in the Urfa region the city of Harran became an influential religious center. However, not only Harran but also the larger Urfa region was of economic and political importance, serving as a major node in a supra-regional trading network. The region's dynamic history was accompanied by major changes in agricultural and livestock use. Besides descriptive landscape-scale studies and few local case studies, it has not yet been systematically investigated how these changes are reflected in landscape archives. Recent geoarchaeological research conducted in the wider surroundings of Göbekli Tepe revealed various phases of increased landscape sensitivity and intensified geomorphodynamic activity. This contribution examines whether the comparison of natural science analyses (e.g., sediments, phytoliths, and dung spherulites) with archaeological and historic sources can reveal turning points in the human-environment relationship.

6 **FIRE HISTORY ASSESSMENT IN HIGH SPATIAL RESOLUTION OF LOW MOUNTAIN RANGES IN WESTERN EUROPE: EVIDENCES FOR PAST LAND USE?**

**Abstract author(s):** Robin, Vincent (LIEC - Lorraine University - CNRS)

**Abstract format:** Oral

Information about past fire regimes provides valuable insights for understanding past landscape dynamics. However, past Human activities in Europe strongly influenced vegetation dynamics and fire history. Therefore, to identify clear and solid patterns of past fire regimes and potential influence on the trajectories of landscapes, it is useful to apply a combination of proxies that may provide highly significant complementary data in order to evaluate past fire regimes with high resolution.

This is what we illustrate here with a multiproxy anthracological dataset for three low mountain ranges in Western Europe, the Harz, the Northern Vosges, and the Ardennes relief. We conducted comparative assessment of various charcoal records from large spatial scale (i.e., micro-charcoal signals from peat-bogs) to high spatial resolution (i.e., soil charcoal signals). The latter proxy also enabled us to assess the type of fuel that fed local fires. Such dataset was complemented by pollen data, which provided insights about human presence, climate constraints and vegetation responses to fire disturbances.

Overall, we identified various patterns of fire and vegetation history, on different spatiotemporal scale. We interpreted these various as the fingerprints of the human socio-cultural development. Moreover, our studies show that our comparative assessment of various paleo-signal permits to gather a more complete picture of the past fire regimes.

7 **IS THE KUNGUR FOREST-STEPPE (PRE-URALS, RUSSIA) A CULTURAL LANDSCAPE?**

**Abstract author(s):** Shumilovskikh, Lyudmila - Schmidt, Monika (Georg-August-University Göttingen) - Mingalev, Vitaliy (Higher School of Economics) - Pereskokov, Mikhail - Sannikov, Pavel (Perm State University)

**Abstract format:** Oral

The Kungur forest-steppe is the most northern outpost of the European forest-steppe located within the boreal climatic zone. Due to its fertile soils, the region is intensively used for agriculture. As a result, 40-50% of the area is covered by arable land and only 10-20% by semi-natural vegetation. How natural is the mosaic vegetation of the Kungur forest-steppe is an open question. First evidence of colonisation with intensive environmental use dates back to the Bronze Age. A strong increase in number of archaeological sites took place at the end of the first millennium BC represented by Glyadnovo culture and during 6th-9th centuries AD - by Nevolino. Finally, the Russian colonization take place. In order to study the nature of the Kungur forest-steppe, we investigated several sediment cores obtained from the region on palynology and sedimentology. Our results clearly show dominance of hemiboreal forests interrupted by deforestation phases corresponding to the settlements periods. An increase of the human impact occurred during occupation of the Nevolino culture, characterized by numerous finds of agricultural tools and pits filled with grains. A strong deforestation of the area and spread of secondary birch forests occurred during the Russian colonization. This period is known for industry development and rapid population growth that led to a massive lumbering of the pre-Ural region during the 18th century. Ancient forests were quickly disappearing especially along the rivers through an intensive forest clearing, frequent fires, spreading of agriculture and overall pasture.

8 **ESR DATING DEPOSITS FROM MIROSAVA CAVE, EASTERN SERBIA: CLUES TO MID MIS 3 (DO 14) HUMAN/CARNIVORE INTERACTIONS**

**Abstract author(s):** Blackwell, Bonnie (RFK Science Research Institute; Dept. of Chemistry, Williams College) - Wolfe, Gabrielle - Skinner, Anne (Dept. of Chemistry, Williams College) - Plavšić, Senka - Mihailović, Dušan - Dimitrijević, Vesna (Department of Archaeology, Faculty of Philosophy, Belgrade University) - Dogandžić, Tamara (Department of Human Evolution, Max Planck Institute for Evolutionary Anthropology, Leipzig) - D.Costa, Jonathan - Yang, Diana - Singh, Impreet (RFK Science Research Institute)

**Abstract format:** Oral

Sites documenting the fauna and climate in Marine Isotope Stage (MIS) 3 (Late Pleistocene) are rare in Serbia. To understand the population density and the level of competition between people and large carnivores during the Middle to Upper Palaeolithic transition, dating that relies on faunal remains is essential. Mirosava is a small cave (~ 18 m2) formed in the Jurassic limestones within the hilly-mountainous hinterland along the Velika Morava River valley near Čuprija, in eastern Serbia. In 2017, test excavations demonstrated that the cave deposits contained abundant faunal remains, accumulated by carnivores. The diverse fauna includes large, medium, and small carnivores (Ursus spelaeus, Crocuta spelaea, Canis lupus, Vulpes vulpes, Meles meles, Felis silvestris), and steppe, but also forest and herbivores adapted to mild climates (Bison priscus, Equus ferus, E. hydruntinus, Cervus elaphus, Dama dama, Megaloceros giganteus, Capreolus capreolus), as well as herpetofauna and fish. Electron spin resonance (ESR) can date mammalian teeth from ~ 5-10 ka to ~ 2-4 Ma, with ~ 2-5% precision. Three teeth, an Equus ferus milk molar, ET55, a Bos or Bison premolar, ET53, and a Canis lupus canine, ET54, were collected from Layer 3 along with 10 associated sediment samples for ESR dating. Sediment samples were analyzed with NAA for U, Th, and K, by powdering to ≤ 100 mesh. U concentrations averaged 0.30 ± 0.02 ppm in the enamel and from 14.23 to 17.42 ± 0.02 ppm in the dentine. With volumetrically and time-averaged sedimentary dose rates averaging 780 ± 66 µGy/y and cosmic dose rates at 56 ± 6 µGy/y, ET55 dated at 48.0 ± 3.1 ka, while ET53 dated to 48.2 ± 2.0 ka. Their mean age, 48.1 ± 1.7 ka, correlates with early MIS (Marine Isotope Stage) 3, and most likely, with the Moorschoofd–Glinde Interstadial, Dansgaard–Oeschger (DO) Stage 14.

**TEPHRA CRYPTOGRAPHY IN NORTH MACEDONIA: PLEISTOCENE SEDIMENTARY RADIOACTIVITY ANALYSES IN PALEOLITHIC DEPOSITS AT GOLEMA PEŠT**

**Abstract author(s):** Blickstein, Joel (RFK Science Research Institute) - Blackwell, Bonnie (RFK Science Research Institute; Dept. of Chemistry, Williams College) - Šalamanov-Korobar, Ljiljana - Kitanovski, Blagoja (National Institution Archaeological Museum of the Republic of North Macedonia, Skopje) - Li, Raymond - Li, Richard - Yang, Diana (RFK Science Research Institute) - Spirova, Marina (National Institution Archaeological Museum of the Republic of North Macedonia, Skopje) - D'Costa, Jonathan - Faija, Mehrin (RFK Science Research Institute)

**Abstract format:** Oral

Large explosive volcanic eruptions produce tephra (ash) deposits that fan out downwind from the volcano itself. Thickly blanketing the ground, the ash shards killed vegetation, extirpating the local fauna for many decades. Respiring volcanic ash can cause silicosis and related lung issues among hominins. Golema Pešt is a cave with Paleolithic site near Zdunje, North Macedonia, whose mouth opens to the southeast at 480 m amsl. Reaching > 5.5 m deep, > 21 flatly lying layer silty-sandy matrix-supported gravel layers with éboulis clasts fill the cave. To measure accurate sedimentary dose rates needed for electron spin resonance (ESR) tooth dates for Golema Pešt, > 125 sedimentary samples from all the layers in Trenches 1, 2, and 5 were analyzed by NAA for their radioactive concentrations. Compared to typical cave sediment, cryptotephra-rich horizons contain high U, Th, and K concentrations, which significantly raise their sedimentary dose rates, while éboulis-rich horizons have very low radioactive concentrations. Found first in Trench 2b, geochemical signatures from the Campanian Ignimbrite (CI, Y5) cryptotephra have now been identified in Trenches 1, 2a, and 5. Moreover, new horizons with high Th-rich concentrations that may hide cryptotephra were discovered at 5-7 other depths within the late Pleistocene deposits both above, and below, the CI-rich horizon, as well as more Th-rich horizons in earlier Pleistocene deposits. Although the presence of cryptotephra in these horizons must be confirmed, the cave's very high radiation dose rates existing at those times would have increased cancer rates among long-term inhabitants. Nonetheless, after each high Th-rich horizon, deposits show that hominins left the remains from their large hearths surrounded by their faunal kills and their lithic tools. Thus, despite the devastation that each tephra eruption must have rained on the Treska Valley during the Late Pleistocene, Paleolithic peoples continued to use Golema Pešt unabated.

**FRESH PERSPECTIVE ON THE LATE NEOLITHIC ABORA SITE IN LATVIA**

**Abstract author(s):** Legzdina, Dardega - Zariņa, Gunita (Institute of Latvian History, University of Latvia)

**Abstract format:** Oral

Abora settlement and cemetery is located in South-eastern Latvia at the Lake Lubāns wetland. It is an inland micro-region approximately 200 km from the coast of the Baltic Sea. Abora is just one of the wetland's 27 Stone Age sites, but it stands out with its many human burials, that are distributed across the inhabitation layers. Archaeological research and excavations at the site took place in the 60s and 70s, and once again in 2008, when organic samples were radiocarbon dated to ~2940 - 2470 calBC.

Over the decades, a robust and interdisciplinary research was carried out on this Stone Age micro-region, incorporating archaeological, palynological, macro-botanical, archaeozoological, and palaeogeographical data. The resulting scientific consensus stated that the Lubāns wetland was the earliest agricultural region in Latvia, with Abora as one of the most prominent Late Neolithic early farmers' settlement.

During the last years, new research has been carried out, based on carbon and nitrogen stable isotope analysis and radiocarbon dating of the human bones. The new data calls for more cautious and detailed analysis of the land use and inhabitation patterns of the Abora site, and consequentially, of the whole micro-region as well. Although the palynological and zooarchaeological material suggests that the Abora people were familiar with animal husbandry and early farming, the carbon and nitrogen stable isotope analysis have not confirmed farming as a significant subsistence strategy. Moreover, correlation between stable isotope data and radiocarbon dates may indicate chronological shift away from terrestrial resources.

In this paper, we integrated earlier research with the new bioarchaeological data and revisit the previous interpretations of human-environment interactions and transition to farming in this Late Neolithic site.

Research funded by Latvian Council of Science, project No. lzp-2020/2-0032.

**SOIL (TRANS)FORMATION IN THE CENTRAL EUROPEAN LOESS ZONE AS EVIDENCE OF ENVIRONMENTAL CHANGE AND HUMAN ACTIVITY DURING THE HOLOCENE**

**Abstract author(s):** Krupski, Mateusz (Archeolodzy.org Foundation; Institute of Soil Science and Environmental Protection, Wrocław University of Environmental and Life Sciences) - Kabała, Cezary (Institute of Soil Science and Environmental Protection, Wrocław University of Environmental and Life Sciences) - Mackiewicz, Maksym (Archeolodzy.org Foundation) - Przybył, Agnieszka (Institute of Archaeology, University of Wrocław)

**Abstract format:** Oral

Soils hold a record of natural and anthropogenic formation processes. This makes them reliable proxies in paleoenvironmental research, especially when preserved prehistoric soils are studied. Such paleosols may be found beneath barrows (kurgans), what additionally allows to place the pedogenesis in a chronological timeframe. By comparing traits of the buried soils, material building the

mounds and present-day reference profiles, it is possible to detect environmental (and cultural) change at the level of individual sites and in timescales spanning thousands of years. Comparisons made between several sites may be of regional significance.

Recent pedo-archaeological research on paleosols and barrows, conducted in the Muszkowice and Głubczyce Forests in the Silesian loess zone (SW Poland) indicates:

1. a widespread presence of fertile, humus-rich chernozemic soils, which dominated in the open, steppe-forest landscape at the onset of the Neolithic (late 6th millennium BC) and well into the Late Holocene. Human activity played a prominent role in maintaining the "openness" of the landscape.
2. a transformation of chernozemic soils into clay illuvial soils (Luvisols/Retisols), that occurred in vast territories of the Silesian loess zone sometime during the Subboreal or Subatlantic. This major alteration was caused by more humid climatic conditions, coupled with the spread of dense, close-canopy, beech-dominant forests. On the other hand, chernozemic soils persisted through the Subboreal and Subatlantic and until the present-day in those places, where deforestation has been sustained by continuous human activity (e.g. due to agricultural needs).

Analogous soil transformations were also identified in other areas of the Central European loess zone (in Saxony and Moravia), what suggests regional significance of the described phenomenon, involving shifts between formation of natural and creation of cultural landscapes.

**CHANGES AT THE TURN OF 6000-5000 BC AND THE ROUNDEL AT NOWE OBJEZIERZE IN THE LIGHT OF THE PALYNOLOGICAL RECORD**

**Abstract author(s):** Czerniak, Lech - Pędziszewska, Anna - Świąta-Musznicka, Joanna (University of Gdansk) - Matuszewska, Agnieszka (University of Szczecin) - Tylman, Wojciech (University of Gdansk)

**Abstract format:** Oral

At the turn of the 6th and 5th millennium cal BC, a vast area stretching from Ukraine to France saw the LBK collapse, ending one of the most important stages in the colonisation of Europe by farming communities. Despite the phenomenon covering a wide vast area and the changes taking place almost simultaneously, they do not appear to have had a single cause and they followed different paths depending on local conditions. In this paper, we analyse one of such cases. The analysed micro-region is a small 'island' located on the northern periphery of the 'Danube World'. What was the key moment for the settlement of this micro-region was the appearance of the first agricultural villages around 5300-5000/4900 cal BC (LBK), followed by a monumental ceremonial centre, in the period 4850-4500 cal BC (SBK). We do not know whether a local LBK - SBK transformation took place and the roundel was a significant driver of social and religious change, or whether the two settlement events were divided by a hiatus and the construction of the roundel started a completely new chapter of local history? Interpretation of the results of a high-resolution pollen analysis performed in a profile from a lake located in the centre of the above-mentioned micro-region will constitute an attempt to answer this question. The palynological data is indicative of the transformation of mixed deciduous forests under the influence of strong anthropogenic pressure. They also illustrate two settlement phases related to the development of an economy based on the cultivation of cereals (mainly wheat) and animal husbandry, which is confirmed by the presence of coprophilous fungi spores and meadow plant pollens in the sediments. Dynamic environmental transformation is evidenced by a significant share of pollen of plants typical for ruderal habitats. Project subsidised by the NSC Poland (2017/27/B/HS3/02925).

**BEGINNING OF THE PREHISTORIC TRANSHUMANCE IN THE POLISH CARPATHIANS. THE CASE OF THE HIGH BIESZCZADY MOUNTAINS (SE POLAND)**

**Abstract author(s):** Pelisiak, Andrzej (Institute of Archaeology, University of Rzeszów)

**Abstract format:** Oral

The High Bieszczady Mountains are located in the Eastern Polish Carpathians in the extreme SE corner of today's Poland. They are located well outside the Neolithic and Early Bronze Age settlement centers. Moreover, they are distinctive by extreme environmental conditions resulting from the altitudes, severe climate, short vegetation period, and barren soils, generally unsuitable for cultivation. Palynological records from peatbogs in Smerek, Wołosate, and Tarnawa indicate human activities in the High Bieszczady Mts from about 3200 BC. Up the beginning of the Late Bronze Age there are exclusively the pasturage traces.

Archaeological investigations in this area begun in 2012. Up to 2020 more than 70 sites dated to the Late Neolithic and Bronze Age were discovered in the high landscape zones between 1000 and 1300 m a. s. l. Most of these sites is located in a close context of fresh and salt water springs. The sites are represented by single finds of stone artefacts and small assemblages of them. They correspond with the pollen record of animals herding performed by Neolithic and Bronze Age people on this area.

Beginning of the transhumant pastoralism in the high mountain landscape zones of the Carpathians was an important turning point in the human activity and the human-environment relations. This started to be practiced about 3200 BC and was coincided with climatic fluctuations, especially with the abrupt cooling event about 3200 BC.

Beginning of summer pastures in the High Bieszczady Mts. also corresponds with intensification of human activities in other European mountains. There is a lot of signals of this process: discovery of the naturally mummified human body found close to the Tisenjoch Pass and the Similaun Mountain Hut on the Austrian- Italian border, stone constructions linked with seasonal pasturage in the French Alps, and numerous artefacts found in the high mountain landscapes.

THE SURPRISING OMNIPRESENCE OF OAK IN THE 3RD AND 2ND MILLENNIA CAL BC IN THE SOUTHEASTERN IBERIAN PENINSULA

**Abstract author(s):** Celma Martínez, Mireia (Prehistory Department, Autonomous University of Barcelona)

**Abstract format:** Oral

Quercus evergreen type is the most ubiquitous anthracological taxon in the southeastern Iberian Peninsula in the Copper and the Bronze Ages, despite the idea of the territorial supremacy of Pinus halepensis interpreted by the number of determined fragments and which has led to an interpretation of mesophytic taxa recession in an earlier moment. The palynological interpretations of over-exploitation and forest degradation have been taken from archaeological and bioarchaeological research in the 1980s and 1990s, which in turn have served as the basis for a large number of anthracological studies in the early 20th century. This has produced feedback in the inferential interpretation sustained over the decades, all based on ecological and catastrophic pessimism regarding the forest management of Metal Ages societies.

This work implements a review of the paleoecological interpretation, specifically, of the forest carrying-capacity and the state of the southeastern Iberian Peninsula forests in the 3rd and 2nd Millennium cal BC. The anthracological data is synthesized to be rethought for a new reading and interpretation of the past forests.

Metal Ages societies were believed to be responsible for the destruction of the southeastern forest, but other territorial limits and social organization can be read from the basis of charcoal remains.

48 taxa are present in the territory and display the biodiversity richness, where territorial limits are represented as well as by rare taxa consumed. This study participates in a new understanding of the society-environment relationship, and the cycle of timber production-consumption in a current sub desert environment.

CHANGING LAND-USE PRACTICES DURING THE BRONZE AGE IN NORTHERN GERMANY: NEW INSIGHTS FROM THE ARCHAEOLOGICAL SITE MANG DE BARGEN, SCHLESWIG-HOLSTEIN

**Abstract author(s):** Feeser, Ingo - Schaefer-Di Maida, Stefanie - Filipovic, Dragana - Kneisel, Jutta (Institute of Pre- and Protohistoric Archaeology, Christian Albrecht University, Kiel) - Dreibrodt, Stefan (Institute for Ecosystem Research, Christian Albrecht University, Kiel)

**Abstract format:** Oral

Palaeoenvironmental research in context of the CRC 1266 (www.sfb1266.uni-kiel.de) aims at reconstructing human impact and land-use changes on different spatial scales. Small sediment archives in the vicinity of archaeological sites, so called near-site archives, strongly reflect local land-use activities. Investigations of sediments from medium to large lakes, so called off-site archives, are commonly used to reconstruct regional developments. By comparing different archives it is possible to differentiate and identify signals of environmental change from a local to over-regional scale as well as quantitative and/or qualitative land-use changes. Approaches of constructing a diachronic over-regional proxy of human impact, based on a combined PCA of high resolution off-site records, were hampered by a qualitative change of human-environmental interaction during the end of the Bronze Age. Near-site investigations in the vicinity of the archaeological site Mang de Borgen allowed the reconstruction of local land-use changes, including pastoral and arable activities. The results indicate that a fundamental change in land-use practices between the 13 to 11th century BC was probably responsible for the observed turning point of human-environmental interaction.

MEDIEVAL MINING AND ITS IMPACT ON PEAT RECORDS: A CASE STUDY FROM CRUZ DO BOCELO MIRE (NW IBERIA)

**Abstract author(s):** Silva-Sánchez, Noemí (Instituto de Ciencias del Patrimonio, Incipit-CSIC) - Biester, Harald (Technische Universität Braunschweig, Institute of Geoecology) - López-Merino, Lourdes (Universidad Complutense de Madrid, Facultad de Farmacia, Unidad de Botánica, ENVIROVEG, grupo UCM 910164) - Armada, Xosé-Lois (Instituto de Ciencias del Patrimonio, Incipit-CSIC) - Martínez Cortizas, Antonio (Universidade de Santiago de Compostela, Facultade de Bioloxía, EcoPast, GI-1553)

**Abstract format:** Oral

The Northwest of the Iberian Peninsula was one of the most important mining hotspots during Roman times, with the estimation that Iberian mines generated 60% of the European lead production (Nriagu, 1983). Mining activity mainly focused on gold but also on other metals. Fingerprints of this activity were extensively recorded on environmental archives such as peatlands and lake sediments. Contrary to this huge evidence, medieval mining signals are more half-hearted, both in the archaeological and palaeoenvironmental records. Although palaeopollution research on peat records in NW Iberia has shown some metal pollution increases during the Middle Ages, they tend to be smaller than Roman levels both in intensity and duration. An exception to this trend was found in ‘Cruz do Bocelo’ mire. Besides a clear metal pollution signal recorded during Roman times, there was also evidence of two medieval peaks. The first, peaking at the 6th-7th centuries, is similar in intensity, but shorter in time, than the Roman signal. The second one, between 10-13th centuries, is both higher in intensity and longer in duration. Preliminary analysis of Pb isotope data indicates that this medieval peak is compatible with the local exploitation of metal resources. In this paper we present the results of ‘Cruz do Bocelo’ palaeopollution study which combines elemental composition by XRF and Pb isotope data. Selected pollen indicators will be also shown in order to evaluate the impact of this possible mining evidence on vegetation. Studies of palaeo-archives located close

to the mining and metallurgy centres are badly needed to decipher the local narratives of these activities – in times of social change and reorganization in particular.

HOW JOANNITES’ ECONOMY ERADICATED PRIMEVAL FOREST AND CREATED ANTHROECOSYSTEMS IN MEDIEVAL CENTRAL EUROPE

**Abstract author(s):** Lamentowicz, Mariusz - Marcisz, Katarzyna (Adam Mickiewicz University, Poznań) - Guzowski, Piotr (University of Białystok) - Gałka, Mariusz (University of Lodz) - Diaconu, Andrei-Cosmin (Babes-Bolyai University, Cluj-Napoca) - Kołaczek, Piotr (Adam Mickiewicz University, Poznań)

**Abstract format:** Oral

During European states’ development, various past societies utilized natural resources, but their impact was not uniformly spatially and temporally distributed. Considerable changes resulted in landscape fragmentation, especially during the Middle Ages. Changes in state advances that affected the local economy significantly drove trajectories of ecosystems’ development. The legacy of major changes from pristine forest to farming is visible in natural archives as novel ecosystems. Here, we present a high-resolution densely dated multi-proxy study covering the last 1500 years from a peatland located in CE Europe. The economic activity of medieval societies was highly modified by new rulers—the Joannites (the Order of St. John of Jerusalem, Knights Hospitaller). We studied the record of these directorial changes noted in the peat profile. Our research revealed a rapid critical land-use transition in the late Middle Ages and its consequences on the peatland ecosystem. The shift from the virgin forest with regular local fires to agriculture correlates well with the raising of local economy and deforestations. Along with the emerging openness, the wetland switched from alkaline wet fen state to acidic, drier Sphagnum-dominated peatland. Our data show how closely the ecological state of wetlands relates to forest microclimate. We identified a significant impact of the Joannites who used the novel farming organization. Our results revealed the surprisingly fast rate of how feudal economy eliminated pristine nature from the studied area and created novel anthroecosystems.

ENVIRONMENTAL IMPLICATIONS OF PAST SOCIOECONOMIC EVENTS IN GREATER POLAND DURING THE LAST 1200 YEARS. SYNTHESIS OF PALEOECOLOGICAL AND HISTORICAL DATA

**Abstract author(s):** Czerwinski, Sambor (Climate Change Ecology Research Unit, Adam Mickiewicz University) - Guzowski, Piotr (Center for the Study of Demographic and Economic Structures in Preindustrial Central and Eastern Europe University of Białystok) - Lamentowicz, Mariusz (Climate Change Ecology Research Unit, Adam Mickiewicz University) - Gałka, Mariusz (Department of Geobotany and Plant Ecology, Faculty of Biology and Environmental Protection, University of Lodz) - Karpińska-Kołaczek, Monika (Climate Change Ecology Research Unit, Adam Mickiewicz University; Center for the Study of Demographic and Economic Structures in Preindustrial Central and Eastern Europe, University of Białystok) - Poniat, Radosław (Center for the Study of Demographic and Economic Structures in Preindustrial Central and Eastern Europe, University of Białystok) - Łokas, Edyta (Department of Mass Spectrometry, Institute of Nuclear Physics Polish Academy of Sciences) - Diaconu, Andrei (Department of Geology, Babes , -Bolyai University) - Miecznik, Magdalena (Department of Nuclear Physical Chemistry, Institute of Nuclear Physics Polish Academy of Sciences) - Kołaczek, Piotr (Climate Change Ecology Research Unit, Adam Mickiewicz University)

**Abstract format:** Oral

We explored past environmental history of Kazanie fen (N-W Poland), in historically sensitive location between main early Piasts centres. We carried out pollen, plant macrofossil, micro- and macrocharcoal as well as non-pollen palynomorph (NPP) analyses continuously in a 1-cm resolution supported by archaeological data and historical written sources. Last ca. 1200 years of the environmental history of the Kazanie fen has been supported by a dense accelerator mass spectrometry (AMS) radiocarbon (14C) dating resolution: 19 dates per 172 cm of the profile. A very high average temporal resolution (7 yrs) enabled comparison palaeoecological records with historical events.

Despite the deforestation close to natural oak-hornbeam forests in 1035 cal. CE, according to the palynological data, no oak timber shortage and associated total deforestation in the early Piast statehood were recorded near the site as suggested by previous research.

However, Czech invasion in 1038 associated with mass depopulation and the domestic crisis reported in historical sources near the site is tentative in palaeoecological record because of probable over-representation of Alnus and Betula alba pollen. Socio-economic factors, not climate was the main catalyst of environmental changes, which intensification has started in the 14th century, as documented by historical and paleoecological data.

The prosperity period was halted by a noticeable socio-economic collapse (from 17th to 19th century) causing depopulation (by ca. 67.5%) and arable land decline by 35% near the site. Paleoecological data indicate a clear socio-environmental threshold mirrored in the decline of all anthropogenic indicators at that time. This caused rapid forest regeneration and occupation of abandonment land, however, with the dominance of pioneer pine as the main stand. Palaeoenvironmental data reported rapid landscape transformation from the beginnings of the 19th century, associated with pastures, meadows, and arable land increase, as well as microcharcoal influx from ca 1950 related to intensified industrial production.

SOIL MACROFOSSILS AS A LAND-USE MARKER: A CASE STUDY FROM NORTHERN LADOGA, RUSSIA

**Abstract author(s):** Salova, Julia (Kazan Federal University) - Belsky, Stanislav (Peter the Great Museum of Anthropology and Ethnography - the Kunstkamera) - Ponomarenko, Elena (University of Ottawa)

**Abstract format:** Oral

The criteria of selecting a place for the new burial ground in the forest zone by ancient populations remain poorly understood. It could be a result of a special clearing at some distinct geomorphological settings or using a previously deforested area, such as a former settlement, for instance. Theoretically, the problem could be solved by the comprehensive stratigraphical study of the multi-layered sites, but in some specific conditions, like in the North-Western Russia with very shallow soils, it seems way too complex. Meanwhile, a study of soil macrofossils may be a clue for understanding the stages of the site utilization.

We applied this approach in the study of the Kylälahti Kalmistomäki burial ground, Northern Ladoga. The site was attributed as a 14th-15th c. local parochial necropolis of the Novgorod Republic.

The excavations also revealed an underlying horizon with peculiar stone structures, belonging to an earlier period. Based on the artifact distribution, the researchers interpreted it as a cremation burial ground of so-called polttokenttäkalmisto type, partially destroyed by later burials, and dated it to the 10th-13th c.

The analysis of macrofossils from the early stage of the Kylälahti, however, discovered the composition rather typical for an occupation layer, than for any kind of a burial site. It includes numerous sherds, partially sooted, fragments of calcified and weathered bones, fish scales, charred and eroded barley grains, ergot, spikelet forks of cereals, Chenopodium. According to the results of the microscopy study, the economy of the local population was based on a combination of cereal farming, fishing and livestock. Thus, the period of 10th-13th c. is likely associated with the habitation site, since it indicates a fairly long-term production activity of people directly in this area. A less likely explanation might be in specific rituals used when the polttokenttäkalmisto burial ground was forming.

PYROGENIC ARCHIVES OF THE CULTURAL LAYERS ON THE TERRITORY OF THE MEDIEVAL CITY OF YAROSLAVL

**Abstract author(s):** Engovatova, Asya (Institute of Archaeology Russian Academy of Sciences) - Golyeva, Alexandra (Institute of Geography RAS)

**Abstract format:** Oral

One of the information resources on the nature and anthropogenic impacts on the city territories in the past are coals of different origin, confining in the soil, – a pyrogenic archive. Types, dimensions and rates of carbonated pieces discovered enable to establish natural fires’ regularity and character. Concerning the human modified soils, they reveal anthropogenic impact on soil and landscape during the city life. One more aspect established is the set of local wood species. Carbonaceous inclusions gained during the archaeological excavations in the historical center of the medieval city of Yaroslavl, located in the center of the East European Plain, were studied as well (city layers of 1220-1238, early 13th century, mid 12th century and arable horizons of 8-10th centuries, Early Iron Age). As background markers we used samples from underlay natural soil horizons. That made possible to reveal the coal volume input into natural soils during due to economic activities. Soil samples of the Early Iron Age coming from arable horizons confine less coal than those from house infill. Anyway, differences between the samples just mentioned are little comparing to the consecutive arable horizons. The burnt bone presence in the early 13th century pyrogenic fraction is typical for cultural layers as well. The set of wood species established nearly corresponding with the middle taiga zone Yaroslavl to be located in. The oak coal pieces from those cultural layers appear to be remains of imported wood. The Early Iron Age arable horizons confine less coal impurities as compared to those Medieval. Probably, that is due both to the less usage of wood coal in fertilizing and pieces’ poor preservation because of natural destruction. The culture layers traditionally confine more pyrogenic material as compared to the arable horizons, the part of larger pieces being higher (probably, the result of plowing).

SOCIETAL RESPONSE TO VOLCANIC ERUPTIONS: HAZARDS IN THE LATE ANTIQUE, MIGRATION PERIOD AND THE BRONZE AGE

**Abstract author(s):** Alinezhad, Khadijeh (Independent researcher)

**Abstract format:** Poster

The Late Antique in Central Europe and the subsequent Migration Period between the 5th and 7th centuries C.E. were a time of insecurity and conflict. Potential hazards driving this societal instability include political atrophy, an unfavourable climate (Late Antique Little Ice Age), pest epidemics (Justinian Plague), and abrupt climatic events such as the large volcanic eruptions in 536/539 C.E. (Oosthoek, 2013; Büntgen et al., 2016; Peregrine, 2020; Gunn and Ciarini 2021). Volcanic eruptions as a natural disturbance have frequently degraded human-environment relationship in prehistoric and historic periods (Sigl et al., 2015; Rao et al., 2017). This study will present a high temporal resolution investigation (~800 years) of a laminated lake sediment record from Kleiner Tornow Lake (Brandenburg, Eastern Germany) using a multiproxy approach: palynology, varve micromorphology,XRF geochemistry, varve counting and 14C-AMS dating.

The vegetation and climate reconstruction, specifically detecting anthropogenic pollen indicators (API) and micro-charcoal data, will enable us to feature the societal processes around the event of 536/539: In order to apply the model to Bronze Age abrupt transformations and to compare the situation between these two time sections.

As the first result of the ongoing PhD- project, our poster will elucidate human resilience during the crisis situation of this time in the form of abandonment and reforestation, transformation and adaptation in the economy, as well as human migration.

SOCIAL NETWORKS OF NON-URBAN SETTLEMENTS DURING THE EARLY AND HIGH MIDDLE AGES IN EUROPE

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Rácz, Tibor (Ferenczy Museum Centre; Pázmány Péter Catholic University) - Ødegaard, Marie (University of Oslo, Institute for Archaeology, Museum of Cultural History) - Makarov, Nikolai (Archaeological Institute, Russian Academy of Science) - Heinonen, Tuuli T. (University of Helsinki, Department of cultures, Archaeology) - Fedorina, Anastasia (Archaeological Institute, Russian Academy of Science)

**Format:** Regular session

This session explores the potentials of the archaeology of small finds and the built environment for the study of social networks and social organisation in Medieval Europe. Large-scale excavations, intensive field surveys and recently, professional use of metal detectors allow us to examine settlement networks on a regional level or on an even larger scale. Changes in these networks, either continuous or sudden, very often originate in changes to the social pattern.

Artefact distribution and typology of objects may be used as a research tool for understanding social patterns and networks. While the mapping of luxury objects may highlight the distribution of power and welfare in medieval societies, small finds, treasure finds or large assemblies of pottery may make equally relevant contributions to our comprehension of the social organisation of past societies. Social and hierarchical relations between and within settlements are also manifested and communicated in the built environment. Therefore, the examination of space and place can be employed to analyse the emergence, continuity and changes in socio-cultural ideas and traditions. That way, the built environment can also be used in studying local and regional settlement patterns, reflecting the complexities of cultural contacts, the transmission of ideas and social change. This session will examine the problems and potentials of this topic. Are there any markers of social stratification in the material culture of rural communities, and what conclusions can be drawn from their spatial distribution? Can residential patterns reflect social structure and in what way? What sort of data can be employed to delineate the hierarchy of medieval settlements?

For this session, we invite speakers with new data on and approaches to material culture, settlement forms and landscape organisation to reveal the vivid and intricate social patterns of medieval communities.

ABSTRACTS:

(RE)ASSEMBLING THE LOCAL? HIERARCHIES AND / OR COMMUNALISM IN RURAL COMMUNITIES IN THE MIDDLE AGES IN SCANDINAVIA

**Abstract author(s):** Svensson, Eva (Karlstad University) - Pettersson, Susanne (Byantikvaren i Oslo)

**Abstract format:** Oral

Two major thought collectives are dominating the historical descriptions on social structure and organisation of rural societies in the middle ages in Scandinavia. With each thought collective usually claiming to be new research, whereas the other is old research.

The first thought collective emphasise hierarchies and social stratifications with dominating, but competing, elites, and subaltern groups such as slaves. Key in this cohort of narratives are the emergence of kingship, with allied and competing elite families and institutions such as the catholic church and the nobility, and the exploitation of various resources and people for their enrichment. Peasant are in these contexts mostly reduced to passive objects, and often victims. The second thought collective stress the importance of active and competent peasants, and play down the importance of the elites in everyday life. In this context, commons and communalism are often forwarded as key for peasant organisation.

In this paper it will be suggested that it does not have to a question of either thought collective, but that it was rather a question of both being relevant, but with differences in scale and geography.

However, as will be argued in this paper, communalism networks, and access to commons, should not be interpreted as signs of an egalitarian society. There were complex ways of imposing hierarchies, and inclusion and exclusion practices also in peasant dominated rural communities in Scandinavia during the middle ages. There were also examples of feudal initiatives within the peasant dominated rural communities.

TRACES OF VILLAGES, SETTLEMENTS, GRAVEYARDS, CHURCHES AND FORTS OF EARLY ÁRPÁDIAN AGE IN THE MOSON PLAIN

**Abstract author(s):** Czuppon, Tamás (Hansagi Museum, Mosonmagyaróvár; Pázmány Péter Catholic University) - Takács, Miklós - Langó, Péter (Research Centre for the Humanities, Eötvös Loránd Research Network)

**Abstract format:** Oral

The aim of our presentation to show and introduce a big settlement project, begun in December 2019. The main questions: how have affected the material culture of the analysed region the formation of the Western border of the Hungarian Principality in the 10th c. and the formation of the Hungarian Kingdom in the 11th c? From comprehensive analyzes of the Moson plain sites we expect an explanation on the questions of the alteration of the western frontier zone. This process including both traditional archaeological analyzes and archeometric examinations to get a more thorough picture about the Moson plain material culture of this era, as a region of the border area.

On the Lébény – Bille-domb settlement site ceramic classification is made for a comprehensive analysis and radiocarbon measurements are made on the chronologically relevant find to clarify the material culture of a village like settlement, not only within the ceramic making practices but also traces of trade connections in a small regional unit on the western border of Hungary.

The archaeological evaluation of the Moson stronghold will include the creation of databases of the material for structural division and internal chronological changes of the features of the excavated site and use the data of archaeozoological investigations for the reconstructing the environmental history of the Moson stronghold.

Detailed archaeological evaluation of Lébény - Kaszás-domb cemetery bring new evaluation of the cemetery based on the analysis of the archeometrical examinations and new periodization of the cemetery base on the data of the radiocarbon-measurements. The analyses will make an overview of the framework of connections to be detected in the grave goods of the western part of the Carpathian basin.

DYNAMICS OF NETWORKS IN A SELF-SUBSISTENT ECONOMY: THE CASE OF MEDIEVAL RURAL MOUNTAINOUS ALBANIA

**Abstract author(s):** Agolli, Esmeralda (Tirana University)

**Abstract format:** Oral

In the archaeological query, research over networks has highlighted an insightful background that attempts to explain various issues related to the control of resources, modes of production, distribution, specialization, exchange, prosperity, trade and so on. It goes without saying that the intensity and nature of networks do define some crucial dimensions to understand that beyond simple routes of communications, others factors including the movement of goods, connection with market, or the character of exchange contribute a great deal to explain the socio-economic dynamics of any given society. By taking into account this potential, against the socio-economic backdrop I discuss the nature of networks in the pre-urban communities of rural medieval mountainous (14th - 19th century) Albania.

By focusing on ethno-historic sources, I seek to analyze what kind of social and economic parameters establish the models of networks in these communities. How do communities in self-subsistence, deeply dependent from the sources of their environment and in a steady demographic growth perceive ‘the connections’ beyond the borders of their kin. To what extent a social custom such as blood feud remains a focal indicator to establish any kind of social and economic network both inside and outside.

I argue that patriarchal ties and extensive loss of human resources through blood feuds keep these communities to a highly isolated setting. By constantly and intensively developing an internal conflict among each other they increasingly a weaken any potential socio-political cohesion or interconnections. In the economic spectrum, for over five centuries, they do not overcome the level of a self-subsistent economic model with limited exploitation of natural resources, household production and only develop casual connections with the regional markets. Both these dynamics define limited and sporadic networks leaning mostly towards an increasing degree of self-isolation.

CHRISTIAN METALWORK AT THE RURAL SITES OF SUZDAL’ REGION, UPPER VOLGA: NEW EVIDENCE ON CONVERSION AND IDENTITY

**Abstract author(s):** Makarov, Nikolaj - Zaytseva, Irina (Institute of Archaeology Russian Academy of Sciences)

**Abstract format:** Oral

Medieval cross-pendants, reliquary crosses and other categories of metalwork with Christian visual motifs constitute an important cluster of archaeological records which is under discussion in connection with the problems of identity and Conversion of Rus’. Rapid growth of this group of artefacts with the broader use of metal detectors in field research puts on the agenda re-examination of the aspects of the scale of their production, their spread, cultural attribution and ritual use. The paper explores Christian metalwork from the sites of Suzdal’ region, which represents one of the largest regional collections of the objects of personal devotion in Rus’ with more than 300 artefacts, accumulated mostly during the two recent decades through the fieldwalking at the rural sites. Recent statistics indicate that Christian objects of the XI-the-XIII-th cc should be regarded as one of the most numerous categories of metalwork, equally common at the rural sites (finds were recorded at 56 sites) and in the towns of Suzdal’ region. The scale of their production and use appears to be much wider, than it was previously believed.

THE CHALLENGE OF CLASSIFICATION AND SOCIAL INTERPRETATION OF HIGH AND LATE MEDIEVAL METAL FINDS. THE CASE OF PEST COUNTY, HUNGARY

**Abstract author(s):** Rácz, Tibor (Ferenczy Museum Centre)

**Abstract format:** Oral

The intensive application of the metal detector device and the growing number of metal finds delivered to the local museums in the last decade has gradually led to the creation of a new database, complementing the data of earlier field surveys and large-scale excavations. The systematic, complex evaluation of these finds has not yet begun; research has dealt in detail only with the analysis of particular objects or several object types.

In my presentation I'll seek to evaluate the metal finds of about forty medieval settlements of the Pest Plain and the Gödöllő Hills lying in Pest County, Hungary. Some of them yielded a few dozen, others several hundred metal finds from the High and Late Middle Ages.

Even assuming the accidental character of the sampling, the large amount of medieval finds is suitable for analysis and a plastic picture of the village network system can be drawn at a regional level. The analysis is prepared by defining and grouping the finds (costume elements, agricultural equipment, household items, liturgical objects, etc.), dating and summing up the numerical data. By investigating merely on the level of objects, I'll try to answer the following questions: What were the typical, widespread metal finds of medieval settlements? What counts as rare, or exceptional, especially valuable, how often they appear in rural setting, and what kind of social network can they be embedded into? Is it possible to draw conclusions on the size, richness and hierarchical status of a settlement by qualitative and quantitative evaluation of metal objects? Can we delineate on the map the centres and peripheries of the region? To what extent can we correlate our conclusions to excavation data and current state of historical research?

RECONSTRUCTING THE RURAL–URBAN NETWORKS IN THE MEDIEVAL AURAJOKI RIVER VALLEY, FINLAND

**Abstract author(s):** Pellinen, Hanna-Maria - Immonen, Visa (University of Turku)

**Abstract format:** Oral

The Aurajoki River Valley in South-Western Finland belongs to the northernmost regions of medieval urbanism. The development of the town of Turku, founded around 1300, is relatively well known, but its surrounding rural settlement has remained poorly understood. In this paper, we will present the new archaeological project that surveys and evaluates the non-urban settlement pattern in the river valley and its dynamics with the urban area. The rural settlement organized into villages began in the river valley in the 5th to 13th centuries, but in the 13th and 14th centuries, a denser village structure and the open-field system emerged. This occurred at the same time as the establishment of the first inter-regional authorities, i.e. the Church, and the Kingdom of Sweden in Finland, and founding of the town. So far only one of the rural villages has been excavated thoroughly, but our project is the first attempt to survey the remaining traces of medieval village in detail, and select some of them for further archaeological inquiry. Presently, the reconstruction of the medieval settlement pattern can be based on the preliminary results of the survey, which can be compared with early modern taxation records. Moreover, the recent boom in amateur metal detecting has discovered new evidence of rural life. The assemblage of metal finds forms an interesting, but challenging contrast with previous archaeological scholarship on the medieval Aurajoki River Valley as it has been mainly based on the distribution of imported and local ceramics in known central sites. In our paper, we will discuss the problems and possibilities of combining the different kinds of sources and evaluate what they can reveal about the rural–urban networks in the Aurajoki River Valley.

FARMER, PRIEST OR NOBLEMAN? NEW AND OLD FINDS FROM DROWNED MEDIEVAL TERPS IN THE WADDEN SEA (NORTH FRISIA, GERMANY)

**Abstract author(s):** Blankenfeldt, Ruth (Zentrum für Baltische u. Skandinavische Archäologie, Schloss Gottorf) - Klooß, Stefanie (Archäologisches Landesamt Schleswig-Holstein) - Majchczack, Bente Sven (Christian-Albrechts-Universität zu Kiel; ROOTS Cluster of Excellence) - Hadler, Hanna (Johannes Gutenberg-Universität Mainz) - Wilken, Dennis (Christian-Albrechts-Universität zu Kiel)

**Abstract format:** Oral

During the great storm surge of 1362, large parts of a flourishing cultural landscape in the coastal marshlands of North Frisia (northern Germany) were devastated.

While some parts of the settlements were preserved and agricultural land could be reclaimed after the flood, other parts sank permanently into the sea. Remnants of the lost terp-sites and their farmland are preserved beneath the present-day Wadden Sea sur-

face. Archaeological research of these terp areas has a long tradition, especially in the vicinity of “Hallig Südfall”. However, for over a century, the documentation of settlement features and the collection of finds has been based on random exposure through the morphodynamics of the tidal flats. Currently, a more systematic approach with regular surveys, using drone photography, field-walking, and metal detection aims to get the bigger picture behind the find sites. Magnetic prospecting and geoarchaeological drilling complement the insight into the settlement patterns of the terps.

This paper focuses on a settlement territory called “Reventlow-area” which yields a large spectrum of outstanding finds from the 12th-14th century. Local and imported pottery as well as metal objects including pilgrim badges, brass bowls and bronze tripod skillets together with folding scales and weights indicate the participation in extensive trade and communication networks. Comparison with finds from other sunken terp sites in the area show a high level of conformity in material culture throughout the region. In addition, the find material provides a broad basis for the discussion about the status of the inhabitants: numerous swords and parts of sword belts as well as objects with liturgical appearance and valuable vessels seem to exceed the spectrum of objects that would be expected for a farming community. This raises the question of whether the North Frisian marsh dwellers held an exceptional social status.

## 8 MEDIEVAL RURAL COMMUNITIES THROUGH THE SPACE AND FINDS. TOUCHES TO THE PICTURE

**Abstract author(s):** Fedorina, Anastasia (IA RAS)

**Abstract format:** Oral

The corpus of narrative sources on Medieval Rus’ shows, though vaguely, how swiftly the social structure changed from the “Viking Age” to the “High Middle Ages.” That means the increase of social groups and property groups that have a name of their own. They are mentioned in chronicles and legal documents, as we can see that they were not equally protected by law. For now, urban social structure is researched more or less. It is especially true for Novgorod Velilkiy. As for the rural communities of Northern Rus’ of 10-14 centuries, they are objective reasons for them to be less researched.

Dealing with archeological data, we have to assume that one’s property status indirectly correlates with one’s social position. So, could we use archeological data to estimate property (if not social) status in rural communities? It is important to see if we can mark how the welfare of separate households and their owners differ from each other and estimate the diversity of social communities.

During the last decades, Suzdal Opolie has produced vast material that characterizes rural settlements and can be looked upon as a basis for a search for such criteria and research tools.

Cultural layer of a significant part of these sites has been considerably disturbed by ploughing-up. Nevertheless, using the spread of ceramics and other artifacts, we can, with a certain degree of conditionality, mark the boundaries of separate estates and reveal the principles of use of the built-up area. Therefore, we can compare material culture of different households and their expected property status. Another aspect that might reflect the changes in the structure of social community could be the change in the settlements layout itself.

## 9 WISKIAUTEN/MOKHOVOYE – FOUR RURAL SATELLITES OF A TRADING CENTRE

**Abstract author(s):** Sirkin, Annika (Centre for Baltic and Scandinavian Archaeology)

**Abstract format:** Oral

In a dissertation completed in 2020, four settlement areas were analysed which seem to be closely related to an as yet undiscovered local Early Medieval trading centre. The research area is located near the Baltic Sea coast and the Curonian lagoon in Kaliningrad oblast’, Russia (former East Prussia). Since the mid-19th century, numerous investigations have been carried out in a nearby burial site known as Kaup. It contains around 500 burial mounds and valuable objects of Scandinavian origin, as well as flat Prussian double-layer graves with rich horse equipment and horse offerings.

The settlement studies in Wiskiauten/Mokhovoye were carried out from 2005 to 2011 by Timo Ibsen (Schleswig). Due to its size and the interdisciplinary research, this site is considered to be the best researched of the region. It yielded a large number of small finds with imports e.g. from Scandinavia and the Rus’. Especially the silver coins (dirham, denier and Byzantine miliaresia) and weights indicate amber trade. Besides the increase of activities in the Early Medieval Time two of the village-sized settlements provide proof of a long lasting settlement continuity.

In the sum of the evidence, it seems obvious that an Early Medieval port of trade must have existed somewhere in the North of the Sambian peninsula, to which the settlements acted like satellites. Since the building structures were badly affected by agriculture, it is difficult to reconstruct the social hierarchies between the four settlement areas. However, the extraordinary amount of more than 130 14C-data gives a good insight into the timeline of the settlement network in the region. Thus the current study sheds new light on the social dynamics and the trading mechanism between the supposed trading port and its hinterland. Furthermore, a new interpretation of geological data gives hints on the supposed location of this trading centre.

### UPLAND VILLAGE NETWORKS: FUTURE PERSPECTIVES FOR THE ANALYSIS OF THE LANDSCAPE IN THE 5TH-9TH CENTURIES UPPER ARLANZA BASIN (BURGOS, SPAIN)

**Abstract author(s):** Domingo Ribas, Guillem (Newcastle University) - Medina Gordo, Sonia - Álvaro Rueda, Karen - Travé Allepuz, Esther (University of Barcelona)

**Abstract format:** Oral

The numerous archaeological sites on the mountain area between the headwaters of rivers Arlanza and Duero (Burgos), in Northern Spain, have drawn the attention of researchers since the 1970s. All of them are known for their rock-cut graves on the sandstone soil, at least dating from the 6th century onwards, arranged around a little church, chapel or hermitage with a foundation carved on the rock floor. Although certain aspects remain partially unexplained, these cemeteries were the main concern of archaeological research. Moreover, between the aforementioned centuries, settlement patterns in the Iberian Peninsula were heterogeneous, manifested significant microregional differences, and entail a complex analysis with scarce written and archaeological sources. Altogether, this led to limited landscape narratives due to a lack of information regarding the habitat, as well as its relation to the funerary areas.

Therefore, in order to properly assess the influence of these communities and their funerary practices on the territory, it becomes vital to create a detailed archaeological record. In this regard, six excavations at the site of Revenga (Burgos) and different archaeological surveys have been carried out over the last years and provide essential information to address the configuration of the landscape, and its underpinning social organisation. Thus, our work intends to complement the archaeological register with data about the natural and geographical aspects of the territory. GIS technologies will be employed in conjunction with quantitative methods to analyse the individual characteristics of each site, which will be linked with the general properties of the settlement network. This will be aimed to identify spatial patterns at various scales, the existence of territorial hierarchies, or any peopling processes. The final archaeological record will contribute significantly to understand the settlement patterns, the establishment of early medieval villages and the development of the Christian landscape in the Upper Arlanza Basin.

## 11

### RURAL SETTLEMENTS ON THE SITE OF MONASTERIES IN THE REGION OF MEDIEVAL NOVGOROD

**Abstract author(s):** Kudryavtsev, Andrey (Institute of Archaeology Russian Academy of Sciences)

**Abstract format:** Oral

Already in 12-13 centuries numerous monasteries were founded in the district of Novgorod. As in the rest of Ancient Russ, these connecting centers of Christian culture played a significant role in the social organization of the city and the city district. As shown by archaeological researches of some Novgorod monasteries, it did not arise on an empty place. In general, the monasteries were preceded by unfortified rural settlements, which appeared already in the X century – the initial period of the urban history of Novgorod.

Studying of the topography and material culture of these settlements adds lots of new data to the field of research of the Novgorodian rural district. The exploration of the processes of transformation of rural settlements into monastic ones is the most important case, especially in the framework of stratigraphic observations. These processes immediately raise a number of unresolved issues: how (much) does the cultural layer of a rural settlement differ from that of a monastery? how are the living area and the necropolis subsequently divided?

The next point of the research is the identification of complexes related to the monastic period. It includes an analysis of things belonging to the circle of Christian antiquities and marking the daily life of the inhabitants of monasteries; amphorae, items of personal piety, pilgrimage items.

Today, the rural Novgorodian region is insufficiently studied, but such researches will allow us to analyze its formation and development. The study of the subsequent process of the foundation of monasteries on the site of rural settlements, the initial period of their history, poorly covered by written sources, has a great potential for exploration. Comparing the urban environment of Novgorod and the isolated spaces of monasteries in the region of medieval Novgorod will give very important results for its urban development history.

## 12

### FINDS FROM THE RECENTLY DISCOVERED PRUSSIAN MEDIEVAL SETTLEMENT INDICATE CONTACTS BETWEEN THE INHABITANTS OF KIEVAN RUS' AND THE OLD PRUSSIANS

**Abstract author(s):** Prassolow, Jaroslaw Aleksei (Centre for Baltic and Skandinavian Archaeology - ZBSA; Institute of Archaeology of Russian Academy of Sciences - IA RAN) - Skvortsov, Konstantin - Khokhlov, Aleksandr (Archaeological Institute of the Russian Academy of Sciences - IA RAN)

**Abstract format:** Oral

Before the WWII, the former East Prussia was one of the best archeologically studied regions in Europe. The emphasis of research was placed on burial mounds, rich cemeteries and to a lesser degree hillforts. Open settlements, on the contrary, remain insufficiently studied even despite the intensification of their research in the last decades. It is difficult to overestimate the importance of their studies both for the reconstruction of the local settlement structure and that of the material culture and contacts of the Old Prussians.

Of great interest is a recent discovery of an unfortified settlement of Privolnoye (former Gunthenen), Kaliningrad region of Russia, which is preliminary dated into the 11th-12th centuries. The results of the first archaeological studies testify to the unordinary character of the monument. Stone pavements in its central part represent the remains of residential and outbuildings. A large number of bronze ingots, bronze and silver smelts and trimmings, weights and casting molds, numerous items indicate presence of a manufacturing center in the settlement. Of particular interest is a stamp for silver lunula plates, which full analogues are known only in the territory of modern Latvia. Finds of coins of the 10th-11th centuries Arab and European rulers indicate a high social and prosperity of the settlement inhabitants. A unique find in the Old Prussians area is an old Russian hanging seal of the Novgorod and later Pskov prince Vsevolod Mstislavich (c. 1095 - 1138), which was originally fastened to a scroll. This find is the first reliable material evidence not only of the assumed contacts between the inhabitants of the region and those of the Kievan Rus' principalities in the 12th century, but also a direct evidence of physical movement of people and objects between the principalities in question and the lands of the Old Prussians.

13

RURAL NETWORKS OF MEDIEVAL STONE MASONS IN EASTERN NORWAY

**Abstract author(s):** Reinfjord, Kristian (University of Bergen)

**Abstract format:** Oral

How were networks of Medieval stonemasons distributed in rural Norway, and how can they be read in an archaeological material of the built environment? By studying the stone technology behind the rural parish church, one gets a glimpse into the social networks of masons. The introduction of stone architecture in Norway in the 12th century laid ground for a new social group of craftsmen, changing building traditions from wood to stone. Established at the cathedrals' building huts, foreign masons were unfamiliar with Norwegian social structures, but developed regional knowledge from the early- to high Middle Ages. The proposed paper study how rural networks of masons distributed and developed in networks of eastern Norway. Meteorologically, this is done by mapping non-human actors such as particular stone quarries, tool marks and architecture, as found as artefact distribution of ashlar, moulded portals, and windows from the central cathedral to the rural parish churches of Eastern Medieval Norway. Architectural distribution, as seen in stone technological features, further mirror how spatial distribution of parish settlements was used by church builders in consolidate the bishopric.

14

THE ROUND BUILDING FOUND IN TATABÁNYA-DÓZSAKERT

**Abstract author(s):** Némethi, János (Pázmány Péter Catholic University, Institute of Archaeology, Budapest)

**Abstract format:** Oral

Pit dwellings with round layouts have been a long-debated topic in the archaeology of the early Magyars. In the late 19th century, scholars thought that the conic shaped river cane huts of Hungarian herders came from conquest era buildings, and were related to traditional finno-ugrian round lavvu tents. Proper archaeological investigation of Árpád-age rural buildings began in the 1950's by István Méri, rewriting these theories. However, the few dwellings with round layouts that do exist – and their possible relations to the nomadic yurt – remain an interesting topic. One of the most unique ones was found in Tatabánya-Dózsakert by Gábor Vékony. The building had Wattle and daub walls and most likely a thatched roof.

Some other Árpád-age round buildings have also been excavated in the Carpathian basin. Among these, the dwelling of Tatabánya represents a rather rare version. Eastern analogies can also be found, the closest are from the Don and Donets region (Krimskoje Gorodische, the left bank Cimljansk fortress, Novalimarivska, Dmitrievskoje).

Finds in the round building of Tatabánya mostly consist of pottery sherds typical of the 10-11th century. One fragment, however, is the shell-shaped handlepiece of a clay cauldron, which has analogies both in the late Avar period of the Carpathian basin and in the Saltovo culture. This find may suggest that some remains of the late Avar population were present within the common folk of the 10-11th century Hungarian state.

The function of round buildings in early medieval rural settlements in Eastern Europe still cannot be decided for sure. What we know for sure is that if they were present, there was only one or a few in a settlement. Different researchers have thought them to be storage houses or plces for the hand mill. In some cases they were definitely used for living.

IMPR - PHYTOLITHS AS A PROXY FOR PALAEOENVIRONMENTAL RECONSTRUCTION

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Peto, Ákos (Hungarian University of Agricultural and Life Sciences) - Kirleis, Wiebke (Kiel University, Institute of Pre-historic and Protohistoric Archaeology)

**Format:** Regular session

Worldwide, phytoliths are used as a proxy to identify changes in vegetation and environments through time. These changes may reflect ecological processes, climatic shifts and/or anthropogenic activities useful to understand the past of human societies and landscapes. Thanks to their resistance to degradation, phytoliths usually preserve well also where other kinds of organic remains are lacking. They can be found in very old deposits (up to 60 million of years), but also have been used to characterize modern ecosystems. Often phytolith studies are carried out in multiproxy palaeo-environmental investigations. For instance, being well

representative of grassland ecosystems, they are complementary proxies to charcoal and pollen analyses, and are useful for the reconstruction of forest history.

The session “Phytoliths as a proxy for palaeoenvironmental reconstruction” invites contributions that use phytoliths for paleoecology, paleoclimatology, and paleobiogeography. According to different sets of archives, e.g. from lake sediments to soil sequences, phytolith studies that are carried out in natural settings and/or in relation with archaeological sites or cultural developments are welcome without any chronological and geographical restriction. Studies where the phytolith record is associated and compared to other palaeo-environmental proxies are also very welcome.

This session is part of the 12th International Meeting for Phytolith Research, or IMPR, the official scientific conference of the International Phytolith Society.

ABSTRACTS:

1

PHYTOLITHS AS PALEOENVIRONMENTAL INDICATORS IN AFRICA AND EARLY HUMAN EVOLUTION: THE GOOD, THE BAD, AND THE UGLY

**Abstract author(s):** Barboni, Doris (CEREGE - Aix Marseille University, CNRS, IRD, INRAE, Coll.France)

**Abstract format:** Oral

The first phytolith studies on the African continent were undertaken in the 1990s. Since then, different approaches have furthered the taxonomic interpretation of phytolith morphotypes, others have improved the ecological and climatological interpretation of phytolith assemblages, while some have contributed to our understanding of the silicon cycle in the tropics. So now, some 30 years later where do we stand? I propose here to look at the positive aspects, the negative ones and the things that could or should have been done better, but were not, regarding the study of phytoliths to document paleovegetation at hominin sites. Three cases studies will be presented: (1) The success story of palm phytoliths in tracing oases in the drylands of Africa (featuring the Aramis and Olduvai sites) (the good); (2) The possibly silent phytolith record of Ethiopian montane forests (featuring the Melka Kunture sites) (the bad); and (3) the poorly known phytolith signal of Amaranthaceae and other abundant herbaceous taxa in eastern Africa (the ugly). This lack of knowledge is an issue given that herbaceous plants other than Poaceae and Cyperaceae may have contributed significantly to the increase of C4 biomass recorded in eastern Africa over the last 10 million years and which is perhaps wrongly interpreted as an expansion of C4 grasslands.

2

EARLY GRASS PALEOECOLOGY IN THE PALEOCENE-EOCENE OF THE SAN JORGE BASIN, ARGENTINE PATAGONIA

**Abstract author(s):** Stiles, Elena - Strömberg, Caroline (University of Washington; Burke Museum of Natural History and Culture) - Erra, Georgina (CONICET - Museo de La Plata, Geociencias) - Gelfo, Javier - Goin, Francisco (CONICET - Museo de La Plata, División Paleontología Vertebrados) - Kohn, Matthew (Boise State University, Geosciences) - Madden, Richard (University of Chicago, Org.Bio./Anatomy) - Traylor, Robin (UC Merced, Natural Sciences) - Bauza, Nicolas (CONICET - Museo de La Plata, División Paleontología Vertebrados; Universidad Nacional de La Plata) - Gallaher, Timothy (University Of Washington, Biology; Bernice Pauahi Bishop Museum)

**Abstract format:** Oral

Modern grasses in the family Poaceae exhibit exceptional taxonomic and ecological diversity, with grassland-dominated habitats covering about 40% of Earth's land surface. Grasslands today occur in a range of temperate to tropical ecosystems, spanning low to high altitudes and wet to arid climates. However, because of the scant fossil record of grasses before the global Oligocene-Miocene spread of grasslands, the ecology of early grasses and their environmental affinities remain poorly understood. To address this gap, we analyze phytolith assemblages extracted from sediment samples collected at the Estancia Las Violetas locality to reconstruct the vegetation of the late Paleocene - early Eocene Rio Chico Group in the San Jorge Basin of Argentine Patagonia. The coastal low-land deposits of the Las Violetas and Las Flores formations of the Rio Chico Group, dated from 57.9±1.1 Ma to <50.6±0.8 Ma, produced phytolith assemblages comprising among the oldest occurrences of grass phytoliths in the fossil record of South America. Preliminary results of phytolith analyses suggest that early grasses in the Paleocene and Eocene of the San Jorge Basin occurred in low abundances in palm and dicot dominated forests. Further analyses of the studied phytolith record will allow us to (1) reconstruct the vegetation and, thus, the ecological context of early grasses, and (2) test for broad floristic changes across the Paleocene - Eocene transition in southern South America, contributing to our understanding of the impact of this period of extreme global warming on terrestrial ecosystems in the Southern Hemisphere.

3 PALEOECOLOGICAL FUNCTIONS OF SHAFTS OF THE DYAKOV CULTURE (EARLY IRON AGE) IN THE MOSCOW REGION (RUSSIA)

**Abstract author(s):** Golyeva, Alexandra (Institute of Geography RAS) - Koval, Vladimir (Institute of Archaeology RAS) - Syrovatko, Aleksandr (Archaeological centre of Kolomna, Moscow region)

**Abstract format:** Oral

Several ramparts of fortified settlements of the Dyakovo culture, located in the southeastern part of the Moscow region, were investigated. It was revealed that all the ramparts were built using significant amounts of household waste. In all cases, there are layers situated within the ramparts showing high total phosphorus content and microbiomorphs (mainly phytoliths and diatoms). This means that these organic matter layers, presumably deriving from manure or household waste were always present in the studied embankments. Consequently, the observed difference of the composition of the embankments is not accidental. Moreover, each shaft has an independent alternation of enriched and depleted organic layers, i.e. there was no single scheme for creating the shaft. Thus, the ramparts of the Dyakovo type settlements were multifunctional. They had both fortification and ecological significance, being a place of discharge of mud and manure accumulated at the place of settlement. The rampart itself was always built on anthropogenically modified soil, and not on the surface of the natural zonal soil.

4 PALEOENVIRONMENTAL RECONSTRUCTION OF CONDITIONS RELATED TO THE OCCURRENCE OF STONE LINES IN PARAÍBA DO SUL VALLEY, SOUTHEASTERN BRAZIL

**Abstract author(s):** Coe, Heloisa Helena (University of the State of Rio de Janeiro; Fluminense Federal University) - Seixas, Amanda (Fluminense Federal University) - da Silva, André Luiz (University of the State of Rio de Janeiro) - Lepsch, Igo Fernando (University of the State of São Paulo) - Parolin, Mauro (University of the State of Paraná) - Macario, Kita (Fluminense Federal University)

**Abstract format:** Oral

The Paraíba do Sul River Valley, located between São Paulo and Rio de Janeiro, the two largest cities in Brazil, comprises a highly altered area with weathered and eroded soils, which emphasizes the need for studies aimed at understanding its evolutionary and environmental dynamics. In this area, the original composition of the Atlantic Forest is currently represented only by small mosaics on a landscape of extensive pasture. This study aims to reconstruct the paleoenvironmental conditions of the Middle Paraíba do Sul River Valley in the late Quaternary and to infer possible changes in climate and vegetation, associated with the occurrence of stone lines. The methodology was based on phytolith, isotopic, soil and 14C-AMS analyses. Some variations in tree density were identified. In the period prior to 9,000 years cal BP, the vegetation was predominantly sparse, in a drier environment, and with lower average temperatures than the current, after which the environment became more humid and the vegetation more arboreal. In the period between 9,000 and 8,200 years cal BP, when the formation of stone lines occurred, it was drier than the previous period, but from 2,900 years cal BP, the environment became progressively more humid and similar to the current environment. The hypothesis of the genesis of the stone lines is one of short distance colluviation linked to periods of concentrated rainfall, with the ability to transport coarser material, since the analysed pebbles are angular and subangular, indicating little reworking.

5 PALAEOENVIRONMENTAL RECONSTRUCTION OF THE PARAÚNA RIVER BASIN, MINAS GERAIS, BRAZIL, THROUGH PHYTOLITS

**Abstract author(s):** Dias, Raphaella (Universidade Federal Fluminense) - Coe, Heloisa (Universidade Federal Fluminense; Universidade do Estado do Rio de Janeiro) - Vasconcelos, Alessandra (Universidade Federal dos Vales do Jequitinhonha e Mucuri) - de Carvalho, Alex (Universidade Federal de Minas Gerais) - Chueng, Karina - Macario, Kita (Universidade Federal Fluminense)

**Abstract format:** Oral

This study aims to investigate paleoenvironmental conditions and infer possible climate and natural landscape changes, in association with geomorphological and fluvial processes in the Paraúna River basin, Southern Espinhaço Mountain Range, Minas Gerais, Brazil. Soil samples were collected in 6 profiles. Throughout the Quaternary, fluvial processes, conditioned by climate, lithostructure, neotectonic movements, and, more recently, by anthropic activities, have contributed to the sculpting of landforms and the development of Phyto physiognomies in this basin. Plants respond to changes in the water table level, soil, and water availability or seasonal flooding, course of rivers, erosion, and transport. The amount of organic carbon and phytoliths in the soil has varied trends, according to the fluvial deposition and erosion processes. In some profiles, phytoliths are well preserved, but phytoliths are also destroyed and corroded in areas subject to direct river action. The predominant phytolith types were TRACHEARY, POLYHEDRAL, ELONGATE, BILOBATE, BLOCKY, and BULLIFORM FLABELLATE, in addition to PAPILLATE in flooded environments. The tree density index was always low and varies according to migration and displacement of the rivers, indicating that the tree coverage was denser when the river was displaced, suggesting that the limiting factor for vegetation in these areas is not the climate but mainly the availability of water. The dates ranged from 17,360 to 1,790 years cal BP. Elementary phytolith, carbon and nitrogen analyses have shown to be very promising in the understanding of geomorphological evolution and environmental changes, especially when associated with other indicators, such as granulometry.

6 PALEOENVIRONMENT AND CLIMATE EVOLUTION RECONSTRUCTION FOR THE LAST 11KA YEARS ON THE COASTAL PLAIN OF SOUTHERN BRAZIL THROUGH MULTI-PROXY ANALYSIS

**Abstract author(s):** Trein Salgado, Eduardo - Pimentel Mizusaki, Ana Maria (UFRGS) - Ferreira Chueng, Karina (UFF) - Gomes Coe, Heloisa Helena (UFF; UERJ) - Cardoso Pacheco Evaldt, Andréia - Girardi Bauermann, Soraia (ULBRA)

**Abstract format:** Oral

Butiazal is a native palm grove ecosystem that occurs in southern Brazil, Uruguay, and Argentina. It is characterized as savanna dominated by palm trees from the Butia genus, which are threatened by monoculture and livestock farming. The Butiazal de Tapes (30°31'39.86"S, 51°21'31.02"W) region is located in southern Brazil on the western shore of the Patos Lagoon and is a remnant of this ecosystem. In this region there are outcrops of Pleistocene coastal deposits, which have been exposed to the Holocene climate and the influence of coastal dynamics. It is therefore an excellent location for palaeoclimatic and palaeoenvironmental reconstruction of the past 11,000 years, in order to understand how this unique ecosystem evolved during this time frame, and which factors were most important in this evolution. For such a reconstruction, analytical tools such as bioindicators (phytoliths and palynomorphs), charcoal particle counting, X-ray diffractometry analysis, total organic matter content determination, granulometry analysis, and carbon-14 AMS dating were performed on a 2 m sediment core. Indications of the presence of Butia in the region from at least 11,125 to 10,751 yr cal BP were identified, along with the importance of the climate during its formation and expansion. Although the climate changes in the analysed interval were not expressive, it was possible to divide the profile into 4 zones according to plant cover and observe the influence of sea-level shifts during the Holocene on the evolution of the palaeoenvironment in the region, along with the evident human influence on vegetation evolution. The data obtained on the butiazaais, which are not previously published in Brazil, are relevant for understanding the evolution of the region's climate and environments and for the environmental preservation of its native ecosystems.

7 PALEOENVIRONMENTAL RECONSTRUCTION OF THE NORTHERN COAST OF RIO DE JANEIRO, BRAZIL, THROUGH SILICA BIOMINERALIZATIONS

**Abstract author(s):** Coe, Heloisa Helena (University of the State of Rio de Janeiro; Fluminense Federal University) - Gomes, Jenifer (Fluminense Federal University) - Gomes, Emily (University of the State of Rio de Janeiro)

**Abstract format:** Oral

The delta plain of the Paraíba do Sul river, on the northern coast of the state of Rio de Janeiro, Brazil, is an important area for paleoenvironmental studies, although studies on vegetation through silica biomineralizations are unprecedented in this region. The evolution of that delta plain gave rise to several lagoons formed under different regimes of sea level and climate variations. This region is also heavily influenced by disorderly occupation that has removed much of the original vegetation cover, replacing it with large sugar cane plantations and pastures. Given the importance of these coastal areas for ecosystems, and due to their vulnerability, this paleoenvironmental reconstruction through silica biomineralizations contributes to the understanding of current and past dynamics in the area. Four geological cores were collected and analyses of phytoliths, sponge spicules, and diatom frustules, sediment granulometry, shell identification, and 14C-AMS dating were carried out. Areas with distinct environmental characteristics were identified. Some were associated with phases of a more continental environment, with finer granulometry and a predominance of terrestrial indicators. In all the cores, the continental or estuarine phase was replaced by a greater presence of liquid surfaces, probably associated with the maximum of the Holocene transgression, about 5,000 years BP. In the most superficial zone of all the cores, a coastal environment was identified, with predominantly herbaceous terrestrial vegetation and flooded areas, and a significant presence of aqueous bodies of fresh water and strong marine influence. This phase is probably linked to a period of marine regression from 4,000/3,700 cal years BP. More recently, human activity has also greatly contributed to changes in the region's vegetation and drainage system. Multi-proxy analysis contributed to a better understanding of the depositional environment dynamic, evolution, and complexity on this part of the Rio de Janeiro coast.

8 PHYTOLITH ANALYSIS INDICATES GRASS COMMUNITY CHANGE BETWEEN THE MIDDLE MIOCENE AND THE EARLY PLIOCENE IN THE CENTRAL ANDEAN ALTIPLANO (PERU)

**Abstract author(s):** Crifò, Camilla - Bremond, Laurent (Institut des Sciences de l'Evolution de Montpellier - ISEM, EPHE, PSL Research University, Université de Montpellier, CNRS, IRD) - Jaramillo, Carlos (Smithsonian Tropical Research Institute; Institut des Sciences de l'Evolution de Montpellier - ISEM, EPHE, PSL Research University, Université de Montpellier, CNRS, IRD) - Strömberg, Caroline (Department of Biology and Burke Museum of Natural History and Culture, University of Washington)

**Abstract format:** Oral

The Tropical Andes belong to the world's biodiversity hotspots, yet our knowledge of the evolution of Andean ecosystems is limited. Palynological evidence from the Amazonian submarine fan, and a marine core in the Ecuadorian Pacific suggests that Andean treeless, high-elevation vegetation (Paramo and Puna) occurred at least by the late Miocene. Palynological evidence from the Descanso Formation in the CAP suggests that a Puna-like ecosystem replaced a mixed vegetation characterised by tropical lowland and montane families around 4.8 Ma, shortly after the Andes had risen to near-modern elevations. It is further thought that Andean uplift caused major changes in climate patterns, resulting in the opening of new ecological niches likely favouring colonisation by grasses. Indeed, grasses are a major component of the modern Puna biome. Yet grass communities of the Descanso Formation are poorly known due to the paucity and low taxonomic resolution of the Poaceae macrofossil- and palynological record.

9

## FLABELLATE PHYTOLITHS IN AQUATIC AND TERRESTRIAL ENVIRONMENTS: AN EXPLORATION OF MORPHOLOGY, MORPHOMETRY AND ENVIRONMENTAL ASSOCIATIONS

**Abstract author(s):** Cordova, Carlos (Oklahoma State University)

**Abstract format:** Oral

Flabellate silica phytoliths form in the bulliform cells on the adaxial surface of leaves of grasses and other monocots. Their variations in shape, size and abundance have been the subject of many studies characterizing wild and domesticated grasses. Although they have received much less attention than other grass phytoliths, a few studies have linked them to particular taxonomic groups while others to particular environments and climatic conditions. This study explores the shape, size of flabellate bulliforms and their abundance in relation to other grass phytoliths in two different sequences in aquatic environments, and one modern transect in terrestrial environments.

In a stratigraphic sequence in a wetland in Azraq (Jordan) flabellate phytoliths vary from a smaller size in the LGM to a larger size into the Holocene, suggesting changes in evaporation possibly related to summer insolation. At this locality, shapes are predominantly fan-shaped and closely associated with Phragmites grasses. In a lacustrine stratigraphic section from Lake Ngami (Botswana), shape and abundance vary along a 17,000-year sequence. Flabellate sizes tend to be less variable across the profile, but abundance and shape vary considerably. Finally, along a sequence of modern surface samples across South Africa, variations occur in shape and size in relation to temperature and precipitation of the wettest month, as well as in relation to precipitation seasonality, which points also to annual evapotranspiration changes, and possibly also to taxonomic variability of grasses along the transect. These three studies suggest that more tests on the environmental importance of flabellate phytoliths are needed for use in paleoecological and paleoclimatic reconstructions.

## MARINE PHYTOLITH: PAST, PRESENT AND FUTURE

**Abstract author(s):** Thilakanayaka, Vidusanka (Key Laboratory of Ocean and Marginal Sea Geology, South China Sea Institute of Oceanology, Innovation Academy of South China Sea Ecology and Environmental Engineering, Chinese Academy of Sciences; University of Chinese Academy of Sciences; National Institute of Fundamental Studies; Department of Oceanography and Marine Geology, Faculty of Fisheries and Marine Sciences and Technology, University of Ruhuna) - Chuanxiu, Luo (Key Laboratory of Ocean and Marginal Sea Geology, South China Sea Institute of Oceanology, Innovation Academy of South China Sea Ecology and Environmental Engineering, Chinese Academy of Sciences; University of Chinese Academy of Sciences; Southern Marine Science and Engineering Guangdong Laboratory) - Madella, Marco (Department of Humanities - CaSEs, University Pompeu Fabra; ICREA; School of Geography, Archaeology and Environmental Studies, The University of the Witwatersrand) - Herath, Dileep B. - Bandara, Gayan (Key Laboratory of Ocean and Marginal Sea Geology, South China Sea Institute of Oceanology, Innovation Academy of South China Sea Ecology and Environmental Engineering, Chinese Academy of Sciences; University of Chinese Academy of Sciences; Department of Oceanography and Marine Geology, Faculty of Fisheries and Marine Sciences and Technology, University of Ruhuna)

**Abstract format:** Oral

Phytolith studies in marine environment are scarce, more specifically, the studies addressing mechanisms of phytolith incorporation into marine sediment (e.g. transporting and deposition). Among the available 24 publications which have studied marine phytolith, 17 studies are done using the sediment from the Atlantic Ocean and 7 studies are from Pacific Ocean, Indian Ocean, South China Sea and the Rose Sea, Antarctica. Most of the Atlantic Ocean studies are done in the vicinity of arid land masses (Sahara, Namibian and Kalahari), where aeolian flux dominates. Hence the aeolian flux is considered as the phytolith transporting mechanism in consensus.

Recent study on Indian Ocean sediment (higher clay, slit and lower sand) shows that there are ~2 to ~40 tonne of phytolith in a deep Bay of Bengal 1cm thick 1km<sup>2</sup> sediment layer in deep BoB which are mainly transported via fluvial systems. Paleovegetation results derived from these data well represent the global paleovegetation in the region. Phytolith observation done using the sediment (high sand particles) near the Irrawaddy river mouth, indicated very low absolute abundance of phytolith, a result which could be attributed to the abrasion of phytolith by sand particles. Care should be taken during phytolith identification in marine sediments as fragments of radiolarian, diatoms and sponge spicules could be misidentified as phytoliths.

Phytolith in marine sediment render new scopes for reconstructing regional paleovegetation and paleoclimate especially in areas where the sediment supply is dominated by fluvial sources. In contrast phytoliths, which are found in areas where aeolian flux subjugates, could be used as a proxy for paleowind patterns and aridity. Sediment which contains higher amount of clay and slit have

higher chances to contain abundant, well preserved phytolith, especially in areas where riverine sediment inputs is prominent such as the sediment fans of Ganges/Brahmaputra, Yellow (Huangho). Yangtze, Irrawaddy, Magdalena, etc...

## PHYTOLITH (MICROBIOMORPHIC) ANALYSIS IN THE CURONIAN LAGOON (SOUTHEASTERN BALTIC) BOTTOM SEDIMENTS STUDY

**Abstract author(s):** Druzhinina, Olga (Herzen State University; Institute of Oceanology RAS) - Golyeva, Alexandra (Institute of Geography RAS) - Napreenko, Maxim (Institute of Oceanology RAS) - Napreenko - Dorokhova, Tatiana - Sosnina, Irina (Institute of Oceanology RAS; Immanuel Kant Baltic Federal University)

**Abstract format:** Poster

Lacustrine deposits are valuable palaeoecological archives due to the diversity of information contained in lake sediments and the continuity of the sedimentation process.

In the last decade, the phytolith analysis having great potential for the reconstruction of local vegetation attracts more and more attention of palaeolimnologists. In 2018, a research of the Curonian Lagoon sediments (southeastern Baltic) started, aimed at the palaeoenvironmental and paleoclimatic reconstructions. The 0.9 m long bottom sediment sequence representing the middle and late Holocene (the earliest date: 6,839 – 6,891 cal BP; IGAN-AMS-6841) was studied by a complex of 9 methods, including pollen, diatom, and phytolith (microbiomorph) analyses (31, 16, 12 samples accordingly). The latter aimed not only to provide extra information on the vegetation development but also to assess the informativity of the method in application to the study of the temperate lakes/lagoons sediments. The analysis was performed according to the standard sample treatment technique (Golyeva, 2008). All samples were found to be suitable for investigation, with a sufficient number of microbiomorphs. The results confirmed that the application of the phytolith analysis in the study of the lagoon bottom sediments contributes to a deeper understanding of the complex dynamics of the coastal and water ecosystems. Thus, the obtained data indicated several intervals in the sediment sequence, which point to the existence of aerial conditions and soil-forming processes on the study location during certain time intervals. That makes phytolith analysis an essential factor in the discussion concerning water level fluctuations and the origin of the Curonian Lagoon.

Acknowledgments. Fieldwork was supported under the state assignment of the IO RAS (topic No. 0149-2019-0013); phytolith, palynological, and diatom analyses were performed with the support of the RSF (grant 18-77-10016), geochronological data obtained with the support of RFBR (grant 18-05-80087).

## PALEOENVIRONMENTAL RECONSTITUTION OF THE HEADWATERS OF THE ARAÇUAÍ RIVER, SOUTHERN ESPINHAÇO MOUNTAIN RANGE, MINAS GERAIS, BRAZIL

**Abstract author(s):** Machado, David (Universidade Estadual de Campinas, Instituto de Geociências, Programa de Pós-graduação em Geografia) - Chueng, Karina (Universidade Federal Fluminense, Instituto de Geociências, Programa de Pós-graduação em Dinâmica da Terra e dos Oceanos) - Coe, Heloisa Helena (Universidade Federal Fluminense, Instituto de Geociências, Programa de Pós-graduação em Dinâmica da Terra e dos Oceanos; Universidade do Estado do Rio de Janeiro, Faculdade de Formação de Professores, Departamento de Geografia) - Silva, Alexandre (Universidade Federal do Vales Jequitinhonha e Mucuri, Faculdade de Ciências Agrárias, Departamento Engenharia Florestal) - Costa, Camila (Universidade Federal do Vales Jequitinhonha e Mucuri, Faculdade de Ciências Agrárias, Departamento de Produção Vegetal)

**Abstract format:** Poster

The Southern Espinhaço Mountain Range, in Minas Gerais, presents predominantly quartzite lithologies that characterize a relief with variations of dissected altitude interspersed with flat surfaces, forming undeveloped soils, associated with a high-altitude tropical climate and the formation of water sources and patchy forests in the Cerrado biome. These environmental dynamics lead to the formation of peat bogs, which, besides being important reservoirs of water and carbon, are also a record of paleoenvironmental changes with evidence of paleovegetational and paleoclimatic changes during the Quaternary. The aim of this research is to contribute to the paleoenvironmental reconstruction of the region of the headwaters of the Rio Preto, in the Southern Espinhaço Mountain Range, using silica biomineralization studies associated with other indicators (multi-proxy analysis). As a peat bog, an environment with low intensity erosive processes, even in the deepest and oldest layers, there was a large amount of well-preserved phytoliths. It was possible to infer that there were no changes in the vegetation type during the analysed interval (from 23,330 to 22,833 years cal BP). However, 4 periods were observed that characterize oscillations from a colder, drier environment in the Upper Pleistocene, to a gradually warmer and wetter environment as the Holocene progressed. When associated with paleovegetation studies in the Cerrado area that used other indicators to reconstruct a regional scenario, despite some differences, the main regional trends were confirmed. Regarding global-scale climatic events, such as the Last Glacial Maximum and the Younger Dryas, the results were very satisfactory.

C. **PALEOENVIRONMENTAL RECONSTRUCTION OF THE ARCHAEOLOGICAL AREA OF SERRA NEGRA, ESPINHAÇO MOUNTAIN RANGE, MINAS GERAIS, BRAZIL**

**Abstract author(s):** Chueng, Karina (Federal Fluminense University) - Coe, Heloisa Helena (University of the State of Rio de Janeiro; Federal Fluminense University) - Fagundes, Marcelo - Vasconcelos, Alessandra (Federal dos Vales do Jequitinhonha e Mucuri University) - Ricardo, Sarah (Nacional Museum Rio de Janeiro Federal University) - Machado, David (Campinas State University)

**Abstract format:** Poster

The Espinhaço Mountain Range (SdEM) has been intensively studied by archaeologists, producing significant knowledge on the regional indigenous history. However, it is also necessary to know the paleoclimatic conditions and environmental context in which such occupations occurred. This work intends to contribute to research developed by the Archeology and Landscape Studies Laboratory of UFVJM in the archaeological area of Serra Negra, located on the eastern side of the Southern Espinhaço Mountain Range, between the Jequitinhonha and Doce river basins. The aim of this study is paleoenvironmental reconstruction of the region using phytoliths. Sediments were collected from the Cabeças 4 archaeological site, in Felício dos Santos, which was occupied during a chronological period between 7,225 and 480 years cal BP. In addition, a sample was collected from each horizon of an organosol profile near the archaeological site. Phytoliths from grasses and palm trees predominate in the samples from the Cabeças 4 archaeological site. These results corroborated with the morphotypes found in the soil profile, which are preserved and homogeneously distributed in the profile. Therefore, the phytolith analyses were promising for inferences of climatic variations and for improving knowledge on the environment in which the regional archaeological occupation occurred.

D. **PALEOENVIRONMENTAL RECONSTRUCTION THROUGH PHYTOLITH ANALYSIS IN THE CASA DA PEDRA SHELLMOUND ARCHAEOLOGICAL SITE, SÃO FRANCISCO DO SUL, SANTA CATARINA, BRAZIL**

**Abstract author(s):** Machado, David (Universidade Estadual de Campinas, Instituto de Geociências, Programa de Pós-graduação em Geografia) - Coe, Heloisa (Universidade do Estado do Rio de Janeiro, Faculdade de Formação de Professores, Departamento de Geografia; Universidade Federal Fluminense, Instituto de Geociências, Programa de Pós-graduação em Dinâmica da Terra e dos Oceanos) - Bandeira, Dione (Programa de Pós-graduação em Patrimônio Cultural e Sociedade - Universidade da Região de Joinville; Museu Arqueológico de Sambaqui de Joinville) - Souza, Rosa (Universidade Federal Fluminense, Instituto de Física) - Rasbold, Giliane (Centro de Energia Nuclear na Agricultura - CENA - Universidade de São Paulo - USP) - Chueng, Karina (Universidade Federal Fluminense, Instituto de Geociências, Programa de Pós-graduação em Dinâmica da Terra e dos Oceanos) - Dias, Raphaella (Universidade Federal Fluminense, Instituto de Geociências, Programa de Pós-graduação em Dinâmica da Terra e dos Oceanos) - Ferreira, Jessica - Voss, Celso - de Sa, Julio Cesar (Programa de Pós-graduação em Patrimônio Cultural e Sociedade - Universidade da Região de Joinville)

**Abstract format:** Poster

Shellmounds are artificial accumulations built by groups of fishermen-hunter-gatherers, consisting of food remains, sediments, artifacts, and vestiges of daily life and funerary rituals. These archaeological sites contain remains of groups of organisms representative of the fauna and flora existing at the time the sites were formed, enabling the recovery of paleoenvironmental aspects related to species biodiversity and biogeography; studies with 14C dating; and the inference of changes in patterns of marine biodiversity and ocean circulation. This study uses the Casa de Pedra shellmound under rock, located in São Francisco do Sul, Santa Catarina, to infer aspects of the paleoenvironment through the analysis of phytoliths extracted from the archaeological matrix of the site. The material presents a good quantity of well-preserved phytoliths and sponge spicules. Among the phytoliths, those from grasses predominate, with the presence of some trees and palms, with no variation in vegetation type during the period of site occupation, between 5,470 and 4,460 cal years BP. Despite the stability of the vegetation, a small increase of the tree cover was identified from the base to the top, which may be related to an increase in humidity, in agreement with other paleoenvironmental studies carried out in the Southern Region of Brazil.

E. **PALEOENVIRONMENTAL CONDITIONS OF THE MARICÁ COASTAL PLAIN, SOUTH-EASTERN BRAZIL, DURING THE HOLOCENE THROUGH SILICA BIOMINERALIZATIONS**

**Abstract author(s):** Santos, Cátia - Coe, Heloisa - da Silva, André Luiz (Universidade do Estado do Rio de Janeiro) - Osterrieth, Margarita (Universidad Nacional de Mar del Plata) - Parolin, Mauro (Universidade Estadual do Paraná) - Pamplona, Fábio (Universidade Federal Rural da Amazônia) - Souza, Rosa - Macario, Kita (Universidade Federal Fluminense)

**Abstract format:** Poster

This study aims to contribute to the deepening of knowledge on the paleoenvironmental conditions of the Holocene coastal plain of Maricá, south-eastern Brazil. Analyses of silica biomineralizations (sponge spicules, diatom frustules, and phytoliths), granulometry, organic matter, carbon content, and 14C-AMS dating were performed. Analysis of the bioindicators enabled identification of three phases with distinct paleoenvironmental conditions related to the evolution of this plain. The first phase (8,500-6,500 years cal BP) corresponds to a wetter period with a predominance of dense shrub/tree vegetation occupying the slopes and coastal plain. The marine bioindicators (sponge spicules, diatom frustules, and bivalves) indicate the existence of an ancient lagoon with shallow waters, connected to the sea by an intermittent tidal channel, in an environment of low hydrodynamic energy. The second phase (6,500-3,000 years cal BP) suggests a period of lower humidity, with a dominance of herbaceous vegetation and increased hydrodynamic energy, possibly caused by wave transposition events and coinciding with the beginning of the lagoon silting process. The

third phase (after 3,000 years cal BP) was characterized by a new period of higher humidity with a return to shrub/tree vegetation, as in the first phase, but with lower density, once again corresponding to an environment of low hydrodynamic energy. A decrease in the quantity of sponge spicules demonstrates the reduced water line of the lagoon and the filling of the same. More recently, this process has culminated with anthropic interventions of urban expansion on the coastal area.

F. **PALEOBIOGEOCLIMATIC RECONSTITUTION THROUGH PHYTOLITH ANALYSIS OF THE MONTE CRISTO CAVE, MINAS GERAIS, BRAZIL**

**Abstract author(s):** Chueng, Karina (Federal Fluminense University) - Coe, Heloisa Helena (University of the State of Rio de Janeiro; Federal Fluminense University) - Vasconcelos, Alessandra (Federal dos Vales do Jequitinhonha e Mucuri University)

**Abstract format:** Poster

This study aims to contribute to the understanding of paleoclimatic variations in the Espinhaço Mountain Range, Minas Gerais, Brazil, during the Quaternary. The Monte Cristo cave is formed in quartzite. Two profiles were collected, the first being an Organosol outside the cave and the second consisting of mostly sandy material inside the cave, in layers that vary in colour between light and dark tones. The results showed that both profiles present a high stock of phytoliths. The phytoliths are well preserved; with a predominance of Spheroid echinate and Spheroid ornate types, besides the presence of Bulliform flabellat, Cross, Bilobate, Rondel and Trapezoid. The tree density index (D/P) is between 0.19 and 0.36, indicating open vegetation. The values of the Bi% index (32.8 to 53%) indicate moderate water stress, similar to previous studies in nearby regions. The Ic (climatic) index showed variation in plant adaptation at lower temperatures, with a predominance of C3 grasses, while the Pa/P index (palm tree density) indicated the presence of palm trees along both profiles. The ages obtained through 14C-AMS in the organosol were from 4,440/4,230 to 2,740/2,430 years cal BP, and the sandy material within the cave from 1,000/920 to 660/550 years cal BP. The phytoliths found inside the cave may be an indication that this material has an allochthonous origin, probably having been carried by flooding in periods under different hydrogeomorphological conditions, which is one of the hypotheses that will continue to be investigated. The vegetation type remained stable during the analysed period, being characteristic of rupestrian fields with the presence of woods in more humid environments.

341 **WIDE HORIZONS - NO LIMITS? DYNAMICALLY FORMULATING THE BOUNDARIES OF ARCHAEOLOGY**

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Lindstrom, Torill Christine (Department of Psychosocial Science, Faculty of Psychology, University of Bergen; SapienCE CoE, Faculty of Humanities, University of Bergen) - Zubrow, Ezra (Dept. of Anthropology, University of Buffalo)

**Format:** Discussion session

The theme of EAA-2021 is: Widening Horizons. – Are there indicators that the horizon limits are being approached? What characterizes the widening? And what characterises the limits?

There is a Norwegian expression: «forstrekke seg», literally meaning: stretching too far, so that muscles and joints hurt, and the expression has the symbolic meaning: To try to encompass and include too much, which may lead to «a gap» in the middle, and ultimately: a falling apart.

Has this happened to archaeology lately?

It has embraced and enrolled DNA-research, anthropology, gender-studies, psycho-neurology, experimental and experiential elements, sensory archaeology, psychological analyses of prehistoric people, art in archaeological imagination, video games, materiality of living memory, urban waste, litterscapes in the present anthropocene, archaeology of popular music, archaeology used to understand homelessness and migrant death along present borders – and much more.

Is there a danger of archaeology loosing its identity because the horizons are too wide? It has been defined as the science of material remains and objects from the past. These objects were produced and used by living people in prehistory, so their objects may tell us something about them, their institutions, and practices. By comparison and analogies, they may even tell us something about ourselves. And indeed, in archaeological method and theory today, there is a tendency towards archaeologies of the contemporary.

How far into our own times and lives can we go, and still call our discipline “archaeo-logy”?

How easily do we risk projecting ourselves too much into the prehistorical analyses?

This session invites papers that are concerned about the limits of widening the horizons of archaeology.

**ABSTRACTS:**

1 **EMPHASIZING THE BOUNDARIES--ARCHAEOLOGY VS BIOANTHROPOLOGY**

**Abstract author(s):** Smith, Elizabeth (State University of New York University at Buffalo)

**Abstract format:** Oral

This paper speaks directly to the symposium abstract: “Is there a danger of archaeology losing its identity because the horizons are too wide?”. It also examines the question of the possible future separation between bioanthropology and archaeology. Bioanthro-

2

pology is a rapidly expanding subdiscipline, in fact, it is expanding more rapidly than archaeology. The boundaries of bioanthropology might be said to be incorporating more of archaeology than archaeology is of bioanthropology. This paper focuses on what happens as this occurs in the present, and it also focuses on possible future outcomes if these processes continue at the present rate. Will there be ‘separation anxiety’ as this change takes place, and what forms might this take? Are there commonalities in the separation processes which make it impossible to understand the different kinds of information paradigms in these two present subfields. Finally, it makes some suggestions about a way forward for both archaeological bioanthropologists and bioanthropological archaeologists.

2

**SHIP OF THESEUS – UNTIL WHEN CAN WE SAY IT IS HIS BOAT?**

**Abstract author(s):** Ribeiro, Artur (Christian-Albrechts-Universitat)

**Abstract format:** Oral

One of the most interesting thought-experiments in philosophy is the Ship of Theseus. In this though-experiment, Theseus’ ship undergoes repairs, and a piece of the ship is renewed every time it goes to harbour. After several years of repairs, the original parts of the ship are completely replaced, and the question this thought-experiment raises is whether we can still call it Theseus ship, even though none of its parts are original anymore.

It seems uncontroversial to say that as time goes by, archaeology requires replacing some older methods for better and/or more advanced ones. The world changes and archaeology must change with it. And this change is good – while some other disciplines languish in outdated methods or close themselves off to change, archaeology has managed to maintain some relevancy due to its changes. In order to stay afloat for decades to come, archaeology needs to have fluidity. At the same time, archaeology should stick to tried and true methods that give it its core-identity. In this discussion, I wish to present a hot-take: there should be two archaeologies; a core-archaeology based on data-recovery, natural scientific techniques, Big Data, and deductive-inductive methods; and a fluid-archaeology, which relies on the social/human/Geistes sciences, intermingles with the arts (e.g., literature, music, film), makes use of methods from history, ethnography, and sociology, and utilizes abductive methods.

3

**UNDERFUNDED OR SIMPLY OVEREXTENDED? ARCHAEOLOGICAL HERITAGE MANAGEMENT IN AUSTRIA**

**Abstract author(s):** Karl, Raimund (Universität Wien)

**Abstract format:** Oral

In the explanatory report to the to the Austrian Monuments Protection Law (DMSG 1999), it says: ‘The DMSG always assumed a clear limitation by considered scholarly selection. Only through this, monuments protection can be conducted with the efficiency that would be lost if too much were scheduled. Thus, it is one of the most difficult tasks of the Federal Monuments Agency (BDA) to select that amount which is necessary from the scholarly perspective and manageable from the administrative one.’ (RV 1999, 39). That makes necessary a law ,... which simultaneously invests the BDA with the necessary powers, but also sets it sufficient limits ...’ (RV 1999, 30).

The BDA employs 15 FTE professional archaeologists for protecting all archaeological monuments in the 83,879 km2 which make up the territory of the Republic of Austria. The annual operational budget of its archaeology department is approximately € 5 Million, also known in professional jargon as ‘peanuts’. Just as a comparison, the annual expenditure by the BDA for protecting (mainly catholic) churches, monasteries and cathedrals is – roughly – 10 times as much. By 2020, just about 1,050 archaeological sites in Austria were scheduled.

Clearly, the archaeology department of the BDA is seriously underfunded! Or is it?

It maintains that any work at any archaeological site, whether it is scheduled or not – of which there are an estimated 1.05 Million in Austria –, falls under its jurisdiction; despite the fact that there is considerable amounts of Supreme Court judicature to the contrary, and none that concurs. So maybe it isn’t underfunded, but that it is overextended, and as a result fails in the main duty assigned to it by § 1 (1) DMSG: the protect those archaeological monuments of such significance that their preservation is in the public interest.

4

**BORDER AND BOUNDARY CONDITIONS OF ARCHAEOLOGY: ARCHAEOLOGICAL LIMITS**

**Abstract author(s):** Zubrow, Ezra (University of Toronto; University at Buffalo)

**Abstract format:** Oral

This paper provides points and context to consider regarding the border and boundary conditions of archaeology. Should the borders be permeable? And if so how and who, if anyone, should control the permeability? Are the boundary conditions of archaeology determined from the inside out or from the outside in? Are they static or dynamic? Should they be one or the other? And if the latter are the temporal aspects controlled or not? Are they reflective or non-reflective?

Boundary conditions place limitations on the domains and impact the range of problems that may be considered as well as the types of theory, models, propositions and perhaps most important the data that limit our research. Do they prevent the dialectic (in the Kuhnian sense) change in the discipline? What is the impact of boundary conditions on innovation in archaeology? In short, what is the relationship between the boundaries and the limits of archaeology?

5

**MULTIPLE “REALITIES” OF ARCHAEOLOGICAL BORDERLANDS**

**Abstract author(s):** Diachenko, Aleksandr (NAS of Ukraine, Institute of Archaeology of the NAS of Ukraine)

**Abstract format:** Oral

The relativity of explanation and interpretation in archaeology is often discussed in the framework of paradigms, each approaching data from its specific theoretical viewpoint. A number of recent studies, such as the works of Ch. Perreault, R.J. Rivers and others, refocuses the issue of the discipline’s limits to the statistical quality of archaeological record. Basing on the examples of empirical evidence and results of mathematical simulations, this paper discusses the grounds of uncertainty of archaeological explanation and reasons for the current relativism at different scales of understanding of the prehistoric past. More specifically, the examples of debates on Neolithic Central and South-Eastern Europe are provided in order to contribute to the discussion of the “forstrekke seg” issue raised by this session organizers. These examples illustrate how the archaeological borderlands, where our aims met our possibilities, reshape prehistoric reality into “multiple realities” of explanations and interpretations. The outcomes of this discussion are considered in frames of the ongoing “Third Science Revolution in Archaeology” (after K. Kristiansen).

6

**STRETCHING OUTSIDE OF THE BOX, OR JUST REINFORCING THE WALLS? ARCHAEOLOGY AND MULTI-DISCIPLINARITY IN THE ERA OF THE NEO-LIBERAL ACADEMY**

**Abstract author(s):** Nilsson Stutz, Liv (Linnaeus University)

**Abstract format:** Oral

“Archaeology is Anthropology or is nothing.” Lewis Binford’s famous words from the era of New Archaeology made the case for an archaeology that reaches outside of the confinements of the discipline itself. Even before the 1960, archaeology always operated outside of its disciplinary boundaries, but with New Archaeology, the horizons widened and they have kept on expanding. This has resulted in a vibrant, creative and exciting field that is difficult to pin down to the point of no longer being recognizable to people outside of the field itself. While there is a movement in status and resources flowing across the multi-disciplinary field, between the natural sciences and the humanities, and back again to the natural sciences (with the current third science revolution as a case in point), long term these “reaches” provide intellectual debate and contribute to our understanding of both the past and the present.

From an intellectual point of view, this creative expansion has been thrilling, creative and enriching. However, it would be a mistake to think that this creativity is not also harnessed by traditional power networks and neoliberal agendas. This paper takes a critical look at the conservative currents below the progressive surface to discuss how power networks, publication strategies, reward systems and flock mentality within our field contributes to upholding power structures and hold back truly creative and innovate thinking.

**WHAT ABOUT ARCHAEOLOGY?**

**Abstract author(s):** Pyrgaki, Marie (Paris I, Pantheon-Sorbonne; Hellenic Open University)

**Abstract format:** Oral

This paper examines archaeology, as a discipline that has reinvented itself multiple times. A discipline that incorporating new methods and theories, branches across multiple new disciplines and across academic boundaries between the natural sciences, the social sciences and the humanities. What means archaeology? Do we really understand each other when we say ‘archaeology’ ? Is the way of perceiving the past limited to the relationship between space and time? Or it actually involves other aspects of our associated life, of our psychology, of our anthropological condition in the present? How archaeology as an academic discipline that, through its expertise about the past, and about human societies broadly, contributes to contemporary debates and solutions? Is continued collaboration a key direction fostering open dialogue and recognition that the human past provides a roadmap for how we got to the present and signposts for where we would like to go in the future?

**IMPR - MICROSCOPY SESSION: PHYTOLITHS IN SOIL THIN SECTIONS**

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Polo-Diaz, Ana (Department of Archaeology. University of Sheffield. Sheffield) - Devos, Yannick (Maritime Cultures Research Institute (MARI) - Department of Art Studies and Archaeology. Vrije Universiteit Brussel. Brussels) - Khamnueva-Wendt, Svetlana (Institute for Ecosystem Research Kiel University. Kiel)

**Format:** Workshop

The present session is structured as a microscopy workshop in relation to the study of phytoliths in archaeological soil and sediment thin sections. As such, the workshop is related to the session “Phytoliths in geoarchaeology and micromorphology”.

We aim to an informal meeting with a focus on the exchange of ideas and experiences in this arena in a practical way. Hands-on microscope work will provide an opportunity for participants to discuss relevant questions regarding methodological approaches, analytical tools and interpretation of results.

The overall goals of the workshop are: to raise awareness among phytolith specialists and micromorphologists / geoarchaeologists on the potential of applying phytolith analysis to archaeological thin sections and promote its practical integration to address archaeological questions.

Participants are welcome to bring their own research materials. Additionally, thin sections related to the presentations of the session “Phytoliths in geoarchaeology and micromorphology” will be made available during the workshop.

This session is part of the 12th International Meeting for Phytolith Research, or IMPR, the official scientific conference of the International Phytolith Society.

343 THE RISE OF PATRIARCHY. AN ARCHAEOLOGICAL VIEW [AGE]

**Theme:** 6. Material culture studies and societies

**Organisers:** Koch, Julia (Keltenwelt am Glauberg) - Montón-Subías, Sandra (Pompeu Fabra University Barcelona) - Berseneva, Natalia (Ural Branch of Russian Academy of Sciences Chelyabinsk) - Matic, Uroš (Austrian Archaeological Institute Vienna) - Hjørungdal, Tove (University of Gothenburg)

**Format:** Regular session

Social injustice and environmental destruction are linked to patriarchal capitalist societies in the current global social discourse. Some decolonial feminists have even claimed that patriarchy did not really exist outside Europe before the advent of modern colonialism. Such discourse usually ignores archaeological research demonstrating that patriarchal systems appeared in different regions of the world long before the modern era. Gerda Lerner’s famous book ‘The Creation of Patriarchy’ situated its emergence in ancient Mesopotamia and made use of archaeological and written sources to support her thesis. Since then, other archaeological and anthropological works have provided explanations for the emergence of patriarchy and documented its presence in prehistoric and/or oral societies with the help of material culture.

We contend that archaeology has much to offer to the current debate on patriarchy and welcome discussions and case studies from all over the world that include (but are not limited to) one or more of the following issues:

- What is patriarchy and how can we identify it using material culture? How can developments in different regions be recorded and reconstructed using archaeological methods?
- Are there regions where turning points in the formation of patriarchy are recorded?
- Are there cases where patriarchy existed without a material correlate that can be identified archaeologically?
- How are patriarchy and material culture inter-related?
- What is the relationship between patriarchy and gender? How does patriarchy create and sustain gender norms? How do people go work around them and what are the consequences? How are masculinity and femininity constructed under patriarchal systems?
- Are unequal gender systems always patriarchal? Are there non-patriarchal unequal societies? Are there unequal societies without unequal gender?

ABSTRACTS:

1 THE RISE OF THE SOCIAL CONSTRUCT “PATRIARCHY”. AN INTRODUCTION

**Abstract author(s):** Koch, Julia (Keltenwelt am Glauberg)

**Abstract format:** Oral

Besides an introduction to the questions of the session, the paper will mainly provide an overview of the most common definitions of the term “patriarchy”. Starting point was the “Mutterrecht”-publication by J. J. Bachofen, with which he created the opposing pair of matriarchy/patriarchy. Some other scholars followed with their essays and studies. The spectrum ranges from classics such as Max Weber and Pierre Bourdieu to feminist authors such as Maria Mies.

The beginning of patriarchal societies was often transferred in nebulous prehistoric periods. But studies on the development of patriarchal structures such as Gerda Lerner’s book have remained rare on the archaeological side. Thus, in his summary of world history, Yuval N. Harari has only state that most societies worldwide were “patriarchally” organised since historic times, but that neither the pathway to inequality nor the causes of the development had been understood so far.

The paper wants to open the discussion in the session if and how we could identify patriarchal structures by archaeological methods. The question is also how we can avoid transferring our own ideas about patriarchy into the past and how we obstruct our view of the past by too rigid ideas about those very prehistoric conditions.

2 WHAT CAN ETHNOGRAPHY TELL US ABOUT GENDER INEQUALITY IN THE PAST? CASE STUDIES FROM THE CHALCOLITHIC SITE OF VALENCINA, SPAIN

**Abstract author(s):** Cintas Peña, Marta (Department of Prehistory and Archaeology, University of Seville; Department of Anthropology, University of Iowa) - Lillios, Katina (Department of Anthropology, University of Iowa) - García Sanjuán, Leonardo (Department of Prehistory and Archaeology, University of Seville)

**Abstract format:** Oral

There is no one definition of the term ‘patriarchy’. Depending on the factor that we focus on – authority, political power, status, coercive capacity and violence, religious influence – several descriptions of the concept are employed in the scholarly literature. How-

ever, all are grounded in a common condition: gender inequality. Therefore, to address patriarchy means that we need to understand the historical conditions that give rise to gender inequality in both the present and past by comparing the lives and experiences of women and men, and other potential genders in non-binary systems.

However, gender inequality and patriarchy are matters of degree rather than of presence versus absence. To complicate matters further, we would argue that the fields of archaeology and anthropology have themselves been patriarchal, and that taken-for-granted categories employed (such as ‘biological sex’) and the knowledge produced in these disciplines are the outcomes of profoundly patriarchal systems.

Given these complexities, how can we work toward dismantling a patriarchal system at the same time as gain insights into the emergence of patriarchy in the past? Our paper will explore the implications of these epistemological realities in both archaeology and anthropology in our understanding of gender inequality in the Iberian prehistoric past. We then present an analysis of those variables that correlate with gender inequality, according to cross-cultural ethnographic studies, and compare these to the evidence recovered from two exceptional tholos burials at the mega-site of Valencina de la Concepción, Spain: Montelirio and tomb 10.042-10.049, dated to the 3rd millennium BCE.

3 MALE DOMINANCE AND THE GENDERED CONTEXT OF DRINKING IN THE EUROPEAN COPPER AGE

**Abstract author(s):** Turek, Jan (Center for Theoretical Study, Charles University, Prague)

**Abstract format:** Oral

Such as in the case of warfare and social power, alcohol production and consumption has traditionally been traditionally related mainly to the male world. However, in most pre-industrial societies, it is women who monopolize the production of alcoholic beverages and dominate their distribution systems. It is probable that the manner and level of alcohol consumption were also defined by social norms that could be described as patriarchy. The gendered context of drinking could be formally expressed in the gender-specific decoration of some ceramics, such as the drinking handled cups of the Bell Beaker Period in Central Europe. Gender differentiation is also evident in the capacity of bell beakers from funerary context in Great Britain and Ireland. The largest beakers came from the graves of men, the medium size from the graves of women, and the smallest beakers were in the graves of children. The reflection of alcohol consumption in the burial rites of the 3rd millennium BC therefore probably included both main gender categories, including children, but this perhaps speaks more about the relationship to the ancestors and the world of the dead and it is not clear to what extent public drinking by women and children in the living society can be expected.

It is possible that even in European prehistory women commonly consumed alcohol, but perhaps not publicly and ceremoniously, like men. In many traditional cultures of the world the consumption of alcohol and other stimulants is mainly related to the male world and these substances are available to women only to a limited extent and often only under male control. This sexist archetype survived in Western civilization until the time of women’s emancipation in the 20th century.

4 PATRIARCHY, MATRIARCHY, OR SOMETHING ELSE? EARLY NOMADS OF THE SOUTHERN URALS

**Abstract author(s):** Berseneva, Natalia (Institute of History and Archaeology, Ural Branch of RAS; South-Ural State University)

**Abstract format:** Oral

The study concerns the Early Nomadic cultural groups (the Sarmatians). They are currently dated from the end of the 6th to the 2nd centuries BCE and the sites are located in the steppe part of Eastern Europe and the Urals. The economy was based on mobile livestock breeding, and there are numerous traces of war activities in the necropolises.

Cemeteries mostly consist of kurgan mounds. The people were buried in a supine position and accompanied by various grave goods including animal sacrificial deposits. Some of the nomadic burial mounds are impressive in their size and wealth.

Sarmatian women are often associated with the ancient «Amazons», and some scholars even suppose this society to be matriarchal. However, the archaeological context is rather ambiguous and it is an area that requires a good deal more attention and study.

This paper has two purposes. The first goal is to investigate the context of male vs. female burials. The second is to answer the question whether there is archaeological evidence of patriarchy/matriarchy/other gender systems in the Sarmatian burials.

5 ‘HAD THE WOMEN BEEN GOOD THEIR TOMB WOULDN’T BE DUG UP TO THEIR THROAT’: DYNAMICS OF DEATH RITUALS IN ALBANIA

**Abstract author(s):** Agolli, Esmeralda (Tirana University)

**Abstract format:** Oral

The first part of the title cites the expression of a local woman from Dibër district during an interview on an ethnoarchaeological research of death rituals around Albania. Beyond this individual account, however, over many other interviews with rural locals around the country, this striking gender contrast occurs commonly while establishing the depth of the tomb pit. The tomb of women goes as deep as the height of their shoulders as opposed to that of men which goes up to the waist. Even currently more sparsely, the ritual is yet encountered in each of the four religious groups (Sunni Muslims, Christians {Catholics and Orthodox}, and Bektashi). In this presentation I look closely to this practice and see what interpretations and rituals do accompany it. Beside the individual accounts, I see its distribution and origin and how a patriarchal society that maintains exclusive patrilineal ties even at death give women an

undermining and prejudicial status. Furthermore, I seek to explain how this evidence could contribute much largely to understand gender roles, and what constrains the actions of women at a patriarchal society.

6 BODY AND MATERIAL CULTURE IN THE MAKING OF FEMALE SUBORDINATION: GUAM 900-1769 AD

**Abstract author(s):** Monton-Subias, Sandra (ICREA; UPF)

**Abstract format:** Oral

In this paper I will subscribe a wide understanding of patriarchy — as any system where there is a domination of women by men — in contradistinction to more narrow uses that restrict the label to the presence of patriarchs or circumscribe it to the modern world. Class, race and gender are today imbricated in the construction of inequality, oppression and discrimination. I contend, however, that they have different historical genealogies which we should not dismiss if we are to understand what is both peculiar and transcultural in female subordination. Archaeology has much to offer to burgeoning debates on these issues since patriarchy is enrooted in our deepest past where both the body and material culture were fundamental to its emergence and maintenance.

I will frame these reflections within the ABERIGUA project, which investigates the impact that modern colonization had on native oral Chamorro in Guam (Mariana Islands, western Pacific). As in many other places of the world, colonial fracture promoted a patriarchal turn on the island. However, how do we need to interpret this turn? As a novelty? Or as an expansion of a pre-existent trend? Precolonial Latte Chamorro bodies and material culture have much to say in answering these questions.

344 HOW MANY PEOPLE? ARCHAEOLOGICAL APPROACHES TO THE STUDY OF PAST DEMOGRAPHY

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Fernandes, Ricardo (Max Planck Institute for the Science of Human History; Oxford University; Masaryk University) - Fernández-Götz, Manuel (University of Edinburgh) - Vander Linden, Marc (Bournemouth University)

**Format:** Regular session

Demography is one of the main topics of interest in the study of past human societies. While many scholars are sceptical of attempts to estimate past population sizes, such assessments constitute important contributions when it comes to discussions on the rate of population growth/demise and of the causal mechanisms underpinning them, socio-economic parameters including production and consumption, human environmental impacts, or the nature of internal and external conflict. With the rise of processual archaeology, attempts to systematise the reconstruction of past population figures gained popularity, and the last two decades have witnessed a renewed interest in these questions. Traditional demographic estimates include the use of settlement (e.g. number of domestic contexts, settlement sizes) and funerary data (e.g. mortality curves, temporal estimates of number of graves). In recent years, there has been an increasing interest in demographic models based on the statistical assessment of radiocarbon dates and of a wider variety of other potential proxies (e.g. pollen studies to determine farming intensity). This session invites papers that employ archaeological approaches to the study of past population size. We welcome contributions with a theoretical-methodological perspective, discussing the potential and limitations of a range of traditional and novel demographic proxies and data modelling methods, as well as papers that present specific case studies.

ABSTRACTS:

1 BIG DATA AND BAYESIAN APPROACHES TO THE STUDY OF ANCIENT POPULATION DYNAMICS

**Abstract author(s):** Fernandes, Ricardo (Max Planck Institute for the Science of Human History; University of Oxford; Masaryk University)

**Abstract format:** Oral

Accurate and precise reconstruction of past population sizes are key element to our understanding of historical developments. When such information is combined with the reconstruction of other past phenomena within multiple spheres (e.g. socio-economic, cultural, technological, environmental) it becomes possible to employ sophisticated modelling methods to identify past causal mechanisms that underlay population dynamics.

In this presentation, two main aspects concerning the study of past population dynamics and of how these relate to other past phenomena will be discussed: 1) data collection efforts as part of the Pandora Big Data initiative for the study of the human past. Pandora's philosophy, organization, and infrastructure will be presented; 2) the development of novel modelling tools, particularly those based on a Bayesian approach, to generate spatiotemporal estimates for a variety of historical phenomena. Such as the spread and speed of spread of human dispersals and the dynamics of population growth and decline. The discussion will also include approaches to taphonomic effects.

Illustrative cases studies from across different regions and cultures will be presented that show-case the research potential of combining large datasets and Bayesian modelling to investigate population dynamics and its underlying historical causes.

2 REASSESSING IRON AGE DEMOGRAPHY: METHODS, APPROACHES AND CASE STUDIES

**Abstract author(s):** Fernández-Götz, Manuel (University of Edinburgh, School of History, Classics and Archaeology)

**Abstract format:** Oral

This paper will explore the possibilities and limitations of approaches to Iron Age demography. For this period, different sources of evidence can be used in an attempt to estimate past population sizes. In addition to cemeteries, which represent the most commonly employed source of information, settlement evidence at well-excavated sites as well as occasional written sources can provide indications about how many people lived in a certain settlement or region, and how population size changed over time. However, it should be noted that each source of information needs to be critically assessed in a contextual manner in order to acknowledge possible biases and limitations. For example, funerary data are often inadequate since in many regions and periods they would only be representative of a rather small segment of the living population, whereas population figures named in written sources could often be exaggerated for political purposes. The need for a contextual approach is exemplified through two specific case studies that include the results of recent research: 1) the Early Iron Age site of the Heuneburg in southwest Germany; 2) and the Late Iron Age necropoleis of Central Spain.

3 BOOM AND BUST - AGGLOMERATION AND DISPERSAL AS A DEMOGRAPHIC PATTERN IN PREHISTORY?

**Abstract author(s):** Mueller, Johannes - Bilotti, Giacomo - Laabs, Juliane - Kerig, Tim - Müller-Scheeßel, Nils (Institute of Prehistoric and Protohistoric Archaeology Kiel)

**Abstract format:** Oral

The study of Neolithic and Chalcolithic settlement regions can be described as follows: certain core settlements emerge, experience an extreme demographic increase and finally disappear relatively abruptly.

Archaeo-demographic methods, such as 14-C SPD (summed probability densities), site/house counts or carrying capacity estimations, are used to reconstruct relative and absolute population sizes on different spatial and temporal scales. Often, those approaches result in the findings of quasi cyclical boom-bust events that seem to be related to major demographic changes. Further, when the settlement patterns are concerned it occurs, that the boom phases correlate with periods of settlement agglomeration and high population density. This phase is succeeded by a dispersal of settlements and assumed lower population densities. Those developments can be witnessed throughout prehistoric Europe in different amplitudes and with regional colorit (e.g. LBK Slovakia and Hungary, Bronze Age Central Europe or Calcolithic Ukraine). The pattern of population growth-stability/settlement agglomeration followed by a population decline/settlement dispersal, followed by growth-stability/settlement agglomeration, etc. we propose is a reoccurring structural feature of prehistoric societies and socio-political networks.

Archaeo-demographic methods are used to reconstruct relative and absolute population sizes of settlements and their hinterlands. In our paper we would like to examine models that explain the “failing” of larger socio-political entities to persist over a longer time span during the Neolithic to Bronze Age in most parts of Europe. Further, we like to stress the non-environmental factors and set ups (e.g. economy, politics, ideology or communication/exchange) which may lead to instability, perhaps reorganization or even collapse of the studied societies or communities.

4 POPULATION CHANGE AND FIRE HISTORY DURING THE HOLOCENE IN THE IBERIAN PENINSULA

**Abstract author(s):** Sweeney, Luke (School of Archaeology, Geography and Environmental Science - SAGES, University of Reading) - Vander Linden, Marc (Institute for the Modelling of Socio-Environmental Transitions, Bournemouth University) - Harrison, Sandy (School of Archaeology, Geography and Environmental Science - SAGES, University of Reading)

**Abstract format:** Oral

In recent years archaeology has witnessed a renewed interest in population history, linked to the development of new techniques, including Summed Probability Distributions (hereafter SPDs). Despite the need for methodological precaution, these approaches provide a first quantitative window on fluctuations in population size the past. In addition to investigating palaeodemographics as such, information on changes in population size is important in order to investigate anthropogenic impacts on the environment. The nature and extent of anthropogenic land-use, reflected in population size and distribution, has a demonstrable impact on modern fire regimes. Reconstructions of past population changes are needed in order to investigate when this influence was first felt. Here, we reconstruct past population size fluctuations, as inferred from SPDs, and compare them to sedimentary charcoal records of changes in fire regimes during the early and middle Holocene in Iberia. Our analyses confirm previous results that identify a marked episode of population growth parallel to the onset of farming in Iberia, but reveal subsequent finer-scale temporal and spatial variation in population size. Changes in fire regimes correlate broadly with known Holocene climate fluctuations, but the charcoal record also indicates finer-scale temporal variation which may be linked to anthropogenic activity. In addition to analyses of the temporal correlations between the two data sets, we consider whether there are distinct geographic patterns that could provide additional insights into the relationship between human activities and fire across Iberia.

5 PEOPLE, HOUSES AND SETTLEMENTS: SMALL-SCALE DEMOGRAPHIC APPROACHES IN THE STUDY OF NEOLITHIC AND BRONZE AGE NORTHERN EUROPE

**Abstract author(s):** Bilotti, Giacomo (Christian-Albrechts-Universität zu Kiel)

**Abstract format:** Oral

The aim of this paper is to reassess the demographic potential of houses and settlements in Northern Central Europe and Southern Scandinavia during the Neolithic and the Bronze Age. It will be structured in two main sections: firstly, I will review how past demographic studies have addressed the topic, highlighting the strengths and the weaknesses of the adopted methods; secondly, I will propose some methodological and practical insights aimed to improve the methodological and theoretical framework. My assumptions will rely on some selected case studies from the aforementioned area and chronology.

In particular, I will evaluate the relationship between settlement data, the traditional backbone for absolute demographic reconstructions, and demography, using proxies such as: house size and structure, house density and the number of houses within the settlements, the area of the settlements and their total number in the different study areas.

In this paper, I will give a greater importance to the micro and meso-regional level, rather than the regional, frequently preferred in palaeodemographic studies. The fundamental questions concerning population size and structure and their change through time will hold, but they will be addressed from a different perspective. In fact, I will try to show the beneficial effects of a “small-scale” approach in our understanding of the effects of local peculiarities in household and settlement organisation and the impact of some processes (e.g. environmental variation, emergence of inequality, adoption of new technologies, interconnectedness, etc.) in the demographic change of local communities.

Finally, this more thoroughly understanding of household and settlement dynamics will help to better correlate the observed demographic transformation and the “global” phenomena often discussed in the literature (environmental change, migration, etc.), possibly allowing a greater confidence in our conclusions.

6 FROM POINT TO PATTERN, AND PATTERN TO POPULATION - A DIACHRONIC STUDY OF POPULATION DYNAMICS IN SOUTHEAST SCOTLAND

**Abstract author(s):** Cowley, Dave (HES Historic Environment Scotland; Department of Archaeology, University of Ghent)

**Abstract format:** Oral

This paper presents a diachronic settlement and landscape archaeology-based study of population in southeast Scotland. Focusing on the Iron Age, with an analysis of settlement and territorial patterning, an explicit approach to considering outcomes of multiple scenarios is adopted. This recognises the impacts of many known unknowns and unknown knowns on modelling ancient populations, such as the reliability of archaeological datasets, the difficulties of establishing contemporaneity of occupation, and the complexity of defining patterns of inhabitation. Situating the available evidence in a settlement and landscape framework allows long-term perspectives to be developed on the division of the landscape into settlement and non-settlement zones. These provide a building block for a discussion of multiple scenarios for the densities, patterning and dynamics of population. The outcomes of the discussion of Iron Age population dynamics are compared with settlement and census data from the 1750s, which date to the cusp of the demographic transition. The analysis of this data identifies the persistence of aspects of landscape organisation, settlement patterning and territorial frameworks, with implications for the assessment of the Iron Age scenario modelling. The long-term perspective highlights the enduring relationships of pre-industrial populations and their landscapes, and provides a framework within which to consider how population dynamics have changed across space and time.

7 A CENTURY IN THE LAND OF ICE AND FIRE: THE SETTLEMENT OF ICELAND

**Abstract author(s):** Cartwright, Rachel (University of Minnesota)

**Abstract format:** Oral

Iceland before the Viking Age migrations was an uninhabited landscape with dense forestation, volcanic activity, and glaciers. In the late 800s AD this all changed with relatively large migrations causing drastic changes in the landscape of the island. Literary sources about the settlement of Iceland, although written down much later, help to shed light on the process of settlement, which is said to have begun around AD 871. In addition to written sources, this paper examines archaeological evidence based on settlement and funerary data, also utilizing aDNA and isotopic studies previously performed in order to understand who was settling in Iceland and the demographic scale of the migratory process. Environmental data also plays a pivotal role in this discussion, with pollen cores showing evidence for the intensification of deforestation and agriculture. Utilizing these different sources in tandem, this paper seeks to develop a model for estimating the population growth throughout the first century of settlement in Iceland.

8 PEOPLE AND HOUSEHOLD IN TERRAMARA SETTLEMENTS. A FLOOR AREA APPROACH REVISED

**Abstract author(s):** Vicenzutto, David (Università degli Studi di Padova. Dipartimento dei Beni Culturali: Archeologia, Storia dell'Arte, del Cinema e della Musica)

**Abstract format:** Oral

Demographic estimates using the ratio between the floor area and the population have had a long development and mixed fortunes. Since Naroll’s paper at the beginning of the 1960s, many constants have been calculated in order to define the living space of an individual and therefore how many people can live in a given floor area. The difficulty of applying this method - especially in prehistoric archaeology - lies in the fact that we are often not able to distinguish human living spaces from those shared with animals or assigned to other activities. Another obstacle is the lack of large dwelling plans, large enough to estimate the whole population of a settlement. In this paper, I will propose potential and limits of estimates methods based on floor area through the case study of the Terramare, fortified settlements of the Po river Valley, in Northern Italy, that developed between the Middle Bronze Age and the Recent Bronze Age. Specifically, I will discuss on one hand the choice of the living space constants and how they have been calculated, and on the other hand the value of the dwellings plans as potential patterns of settlements living areas. Moreover, in order to calculate the population in settlements without house data, I will focus on the elaboration of other constants based on dwellings patterns. Finally, I will try to trace the demographic variation of Terramara settlements through time, both in terms of people and household numbers.

9 THE INTERPLAY OF DEMOGRAPHY AND POLITICAL ECONOMY: ASSESSING THE IMPACT OF THE EGYPTIAN LATE BRONZE AGE DEPORTATION POLICIES

**Abstract author(s):** Langer, Christian (Peking University)

**Abstract format:** Oral

Demographic data are integral in gauging the organization of societies beyond population sizes and the consumption. This paper discusses the interplay between research into demography and political economy and raises the question whether archaeological modelling can capture or trace the dynamic reality of migration, in this case the Egyptian deportation of the Late Bronze Age between 1500 and 1100 BCE. A review of population estimates for the Egyptian, Nubian and Southwest Asian societies marks beginning, combined with the related estimates of the size of the Egyptian workforce needed to sustain the population. Then the Egyptian deportation policies are introduced alongside their supply chain and geographic scope. The analysis of the impact of the Egyptian policies on adjacent societies as well as the Egyptian merges demography and political economy: only population estimates allow us to assess that impact, enabling further research questions about demographic and interregional dynamisms. In this sense, the data suggest that especially the southern Levant was hit hard by the deportation policies that targeted primarily younger individuals capable to work in Egyptian agriculture; resulting in a continual – albeit seemingly low – population loss that aggravated over several generations and probably led to or exacerbated intra-regional conflict. This scenario makes one wonder whether the Egyptian policies did contribute in any way to the so-called Late Bronze Age collapse, e.g. by making societies less resilient due to an unfavourable demographic change. In turn, Egypt itself cemented its position as the eminent great power in the long term through wealth accumulation by dispossession. Raising these issues is only possible thanks to populations estimates and quantitative approaches to Egyptian deportations. The questions is whether archaeological modelling can a) confirm the scenario outlined above and b) assess its impact leading up to the Late Bronze Age collapse.

10 AN ATTEMPT TO ESTIMATE THE POPULATION SIZE OF SARMIZEGETUSA REGIA, THE CAPITAL OF THE DACIAN KINGDOM

**Abstract author(s):** Petan, Aurora (Study Centre of Dacica Foundation)

**Abstract format:** Oral

Sarmizegetusa Regia was the capital of the Dacian Kingdom from its foundation in the middle of the 1st century BC until the Roman conquest of Dacia in 106 AD. The site is located in a mountainous area of southern Transylvania (Romania), at a maximum altitude of about 1200 m. It is assumed that the capital, which had obvious urban characteristics, spread over an elongated hill of almost 4 km and had 4-5,000 inhabitants at its peak, but this number is just a guess.

The aim of this paper is to make an estimate of the population size of the Dacian royal city based on archaeological data. The task is hindered by some important issues as the unclear relationship between the central site and the surrounding settlements, the small percentage of excavated surface, and the absence of graves. However, the site has a unique peculiarity that is useful for a demographic investigation: because of rough terrain, the houses were built almost exclusively on artificial terraces cut into the hillsides. The area was inhabited only in Dacian times and consequently, the landscape has remained almost entirely unaltered, except for slight soil erosions. Therefore, in my presentation I intend to 1. question the extent of the city, 2. present an inventory of man-made terraces and discuss their functionalities, and 3. analyse the types of buildings and estimate the average number of inhabitants per household.

A COMPARISON OF THE RELATIONSHIP BETWEEN SUBADULTS AGE-AT-DEATH AND LONG BONE GROWTH FROM MEDIEVAL ENGLISH URBAN CITIES

**Abstract author(s):** White, Sina (University of Kent, School of Anthropology and Conservation, Skeletal Biology Research Centre) - Newman, Sophie (University of Sheffield, Department of Archaeology) - Primeau, Charlotte (University of York, Department of Archaeology) - Deter, Chris (University of Kent, School of Anthropology and Conservation, Skeletal Biology Research Centre)

**Abstract format:** Oral

Many medieval English towns that were known for being a defence or Christian religious centre flourished into urban areas. People felt safer and protected living in these areas, which caused the population to increase. Highly populated cities are known to have experienced issues with sanitation due to poor waste management and inadequate food supply which could have led to dietary deficiencies. The skeletal development of children who migrated to, or were born in, an urban city may have been affected by poor diet and pathological conditions. Therefore, the aim of this research is to identify if age-at-death and long bone lengths differ significantly, indicative of growth disruption, between subadult individuals living in various medieval English towns.

The London Atlas of Human Tooth Development and Eruption was used to reconstruct age-at-death for subadults recovered from St. Gregory’s Priory and Cemetery (11th to 15th century AD), The Black Gate Cemetery (8th to 12th century AD), and All Saint’s Church (11th to 14th century AD). Subadults from Raunds, a rural cemetery, (10th to 11th century AD) were also included as a comparative sample to identify possible differences that can be attributed to urbanisation. Individuals were placed into one of two age groups: birth to 11 years or 12 to 17 years age groups. The humeri, radii, ulnae, femurs, tibiae, and fibulae were measured using an osteometric board. Possible differences in age-at-death and long bone lengths between subadults from medieval Canterbury, Newcastle, York, and Raunds were assessed using a Kruskal-Wallis H test. This analysis provides an understanding of the relationship between age and long bone lengths, and by proxy subadult health, in different urban environments in Medieval England.

A. POPULATION DYNAMICS IN THE WESTERN SCHELDT BASIN FROM THE MESOLITHIC PERIOD TO THE IRON AGE: SPDS AND SETTLEMENT DATA

**Abstract author(s):** Van Maldegem, Elliot - Crombé, Philippe (Ghent University)

**Abstract format:** Poster

The western half of the Scheldt drainage basin has been a dynamic region since at least the Mesolithic period. The area has been extensively studied during the preceding decades leading to the discovery of increasing amounts through developer-led archaeology. The total number of sites exceeding several hundreds in western Belgium and Northern France, a large part of which have been extensively dated.

The high amount of radiocarbon dates present opportunities of reconstructing paleo-demographic dynamics through the use of summed radiocarbon probability distributions and site counts. Both methods have proven popular and successful tools for understanding population dynamics, yet both have inherent flaws. The use of both proxies allows for the comparison of the results and testing of the validity of both methods.

After careful critical selection of the data we utilize MCMC- and KDE-models of the radiocarbon data and raw count and aoristic weighing of the settlement data to form a preliminary model of demographic evolutions within the study area.

346 MORTALITY, MATERIALITY, AND MEANING – EMPLOYING ARCHAEOLOGICAL MATERIAL SCIENCE FOR THE RECONSTRUCTION OF FUNERARY AND RITUAL PRACTICES

**Theme:** 6. Material culture studies and societies

**Organisers:** Fundurulic, Ana (Sapienza University of Rome; University of Évora, HERCULES Laboratory) - MacRoberts, Rebecca (University of Évora, HERCULES Laboratory)

**Format:** Regular session

Developing analytical methods, from microscopic analysis and molecular-based approaches, organic residues, ancient DNA to chemical structures and isotope ratios, allow us to study mortuary practices in a more detailed and inclusive way. As an intentional and direct deposition, the material evidence produced by treatments of the human body after death, and the rituals that surround them, hold a great investigative potential, reflecting the social context, identity and dietary habits of the living, as well as their relationships towards death and afterlife. Furthermore, specific burial conditions can offer a better preservation to more sensitive materials like those of organic nature that are more susceptible to decay and biological oxidation, including the body itself, food and beverages, textiles, raw and construction materials, natural products, and manufactured substances, among others. However, if those remains are not detectable by the naked eye, valuable information could be overlooked and excluded from the interpretation of burial practices. That is why synergetic research, including aspects of archaeological material science, is beneficial for the integral understanding of funerary rituals through time. Examining the materiality of burials on a microscopic and atomic level enables the exploration of a wide spectrum of subjects central to mortuary archaeology allowing a more subtle reconstruction of all the processes involved in dealing with death. This session welcomes researchers, regardless of the study region or chronology, to share the methods and results of their interdisciplinary projects focused on material remains from funerary spaces. Therefore, studies involving advanced techniques for the analysis and reconstruction of funerary and ritual behaviour are encouraged.

ABSTRACTS:

1 EXPLORING THE QUANTITATIVE WEALTH OF PAST PEOPLE. A CASE STUDY FROM SULTANA-MALU ROȘU CEMETERY (ENEOLITHIC, ROMANIA)

**Abstract author(s):** Radu, Valentin (University of Bucharest) - Mărgărit, Monica (‘Valahia’ University of Târgoviște; ‘Vasile Pârvan’ Institute of Archaeology) - Lazăr, Cătălin (University of Bucharest)

**Abstract format:** Oral

The Sultana-Malu Roșu cemetery is a typical Eneolithic extramural cemetery that was used by two communities belonging to the Boian and the Gumelnița cultures, that covers the whole 5th millennium BC and the beginning of the 4th millennium BC.

The archaeological research in this cemetery is an ongoing project, with 106 graves discovered until the present. One of the most spectacular graves discovered until now was Grave no. 92. It was identified in the foundation trench of C1/2014 construction that cut this earlier grave. The pit was typical, oval shape, and it contains a young female skeleton, oriented E-W. Grave no. 92 was the most richly funerary feature of all the graves investigated here until now. Its funerary inventory includes over 3200 pieces. The beads were made of exotic raw materials, as Spondylus shells, and bone, stone, Lithoglyphus naticoides shells, bone, marble, malachite, clay and red ochre. The personal ornaments show use-wear on their surface proving that they have been worn before being deposited in the grave. Moreover, the pieces have different degrees of use-wear what illustrates that the broken or lost items were replaced and thus, they were accumulated at different time intervals.

The aim of the current paper is to explore the particular ritual practices used in case of young women buried in grave no. 92 in order to identify some social, ritual or economic meanings of this kind of deposition.

This work was supported by a grant of the Romanian Ministry of Education and Research, CNCS - UEFISCDI, project number PN-III-P4-ID-PCE-2020-2369.

2 CANOPIC JARS OF THE ALTAI MUMMIES

**Abstract author(s):** Ochir-Goryaeva, Maria (Kalmyk Research Center Russian Academy of Sciences)

**Abstract format:** Oral

At present the scholars have at their disposal a number of well-preserved mummies recovered from kurgans of the Pazyryk culture. Every one of them has been examined with the help of scientific methods. As a result of studies conducted for many years it has been established that the Pazyryk population subjected to mummification not only their noble but also commoners. But the question—what the procedure was concerning the storing and keeping of the removed entrails, including the brain, heart and abdominal organs—has remained open so far. The article discusses sets of dishes originating from Gorny Altai burial sites of the Pazyryk culture dating back to the Scythian epoch. A close examination of their arrangement in the tomb allows the present author to make a conclusion that a set of three vessels: ceramic, horn and wooden were strictly for individual “use”. Of great importance is the fact that each of the three vessels—round bottomed horn and wooden ones and even the flat-bottomed ceramic one were put on the ring pads stitched together, which were sometimes joined to the mat on the pit floor. Moreover, in some of the burials these three vessels and the buried humans were tied together with a woolen rope, its two ends tied to the little finger of the deceased. In view of this evidence, the author assumes that the three vessels were used as canopic jars, i.e. they contained the entrails of the deceased removed on their mummification. In search of a parallel the author refers to the Egyptian canopic jars put tightly together in a special box beside the mummies.

Funded by government grant No. 075-15-2019-1879.

3 FOOD AND BEVERAGES AT THE FUNERARY BANQUET OF VILLANOVAN VERUCCHIO (RN, ITALY): FIRST RESULTS OF CONTEXTUAL AND BIOMOLECULAR ANALYSES

**Abstract author(s):** Patrizi, Giulia (Laboratory of Analytical and Isotopic Mass Spectrometry, University of Salento)

**Abstract format:** Oral

Verucchio (RN, Italy) is one of the most important Villanovan sites of the Final Bronze-First Iron age. It is situated on the top of a hill that dominate the Marecchia Valley and about hundred kilometres from the Adriatic coast.

Although the settlement area has not been investigated yet, four nucleus of cremation burials, called Lavatoio, Moroni-Semprini, Le Pegge and Lippi, have been found over the hillslopes around the village. Thanks to their excavation, it has been possible to collect interesting data useful for understanding the symbolic representation of the banquet during the funerary ritual. The latter appears filled of meanings and complex symbolism difficult to decode. For this reason, a multidisciplinary approach is necessary to comprehend both the functions of the excavated materials and the relevant actions of the funerary practice.

The present communication will illustrate the integration of the contextual analyses, which involved the revision of the published material and the ex novo documentation of the ceramic vessels, with the biomolecular analysis.

The analysis of ceramic pottery has allowed to distinguish, identify and quantify both the finds related to the funeral ceremony of the living for the deceased, both those placed as personal equipment of the dead.

The results obtained from the analysis of organic residues, although preliminary, showed a remarkable degree of lipid preservation, both in the defunctionalized ceramic and in the one accompanying the deceased. Different types of food offerings have also been identified, some connected to the dietary habits of the living, other strictly related to the death, and overall permitted to understand the function of the vessels and the connected actions.

4

**NEOLITHIC STONE CIST GRAVES OF THE AOSTA VALLEY (NORTHERN ITALY). CLARIFYING THE 5TH MILLENNIUM BC CHRONOLOGY OF WESTERN ALPINE CEMETERIES**

**Abstract author(s):** Steuri, Noah (Department of Prehistory, Institute of Archaeological Sciences, University of Bern) - Martinet, Francesca - Raiteri, Luca (Regione autonoma Valle d’Aosta, Dipartimento Soprintendenza per i beni e le attività culturali) - Milella, Marco (Department of Physical Anthropology, Institute of Forensic Medicine, University of Bern) - Szidat, Sönke (Department of Chemistry and Biochemistry, University of Bern, Switzerland; Oeschger Centre for Climate Change Research - OCCR, University of Bern) - Lösch, Sandra (Department of Physical Anthropology, Institute of Forensic Medicine, University of Bern) - Hafner, Albert (Department of Prehistory, Institute of Archaeological Sciences, University of Bern; Oeschger Centre for Climate Change Research - OCCR, University of Bern)

**Abstract format:** Oral

Research on the Neolithic cist graves of the Chamblandes type mostly focused on sites around Lake Geneva and the upper Rhone valley in Switzerland. For the cemeteries of the adjacent Aosta Valley (Italy), only few information is available and mainly a lack of radiocarbon dating is responsible for that research gap.

However, this situation is deceptive about the scientific potential of this region: Within the framework of a Swiss National Science Foundation supported research project, we identified about 120 stone cist graves from ten different sites in the Aosta Valley. However, due to the lack of distinctive grave goods and missing absolute dating, their chronological position was unclear until now.

Here we present the first extensive series of radiocarbon dates from Neolithic stone cist graves of the Aosta valley. A total of 26 human bone samples from 19 graves were analyzed at the LARA radiocarbon laboratory of the University of Bern. 14C data point to unexpected early dates for the two largest cemeteries of Villeneuve (4800-4550 BC) and Vollein (4500-4350 BC). This result identifies the cist graves from the Aosta valley belong to the oldest known Chamblandes type graves ever discovered. Altogether, our study provides new evidence about the evolution of this burial practice and intra-Alpine relations.

5

**FUNERARY ACTIVITY IN THE CAVES OF THE WESTERN PYRENEES DURING THE LATE PREHISTORY: NEW RADIOCARBON DATES OF HUMAN REMAINS**

**Abstract author(s):** Cubas, Miriam (Universidad de Alcalá; Sociedad de Ciencias Aranzadi) - Peyroteo-Stjerna, Rita (Uppsala University; UNIARQ, Centro de Arqueología, University of Lisbon) - Quevedo-Semperena, Izaro (University of Valladolid; Sociedad de Ciencias Aranzadi) - Tapia, Jesús (Sociedad de Ciencias Aranzadi) - Armendariz, Ángel (Instituto Internacional de Investigaciones Prehistóricas de Cantabria-Universidad de Cantabria; Sociedad de Ciencias Aranzadi) - Rios-Garaizar, Joseba (CENIEH-Centro Nacional de Investigación de La Evolución Humana) - Santamaria, Urko (High Yield Research Group of Prehistory. Universidad del País Vasco/Euskal Herriko Unibertsitatea) - López-Onaindia, Diego (Université de Bordeaux) - Gómez-Olivencia, Asier (Dpto. Geología, Facultad de Ciencia y Tecnología, Universidad del País Vasco/Euskal Herriko Unibertsitatea; Sociedad de Ciencias Aranzadi; Centro UCM-ISCIl de Investigación sobre Evolución y Comportamiento Humanos)

**Abstract format:** Oral

Caves have been often used as funerary space through most European Prehistory, although the frequency of the mortuary events are highly variable over the time. This is clearly visible in the archaeological record of the Western Pyrenees, a territory with a large number of caves. Human remains have been mostly documented on the surface of the caves in apparent association with other elements of the material culture, and thus the chronology of these funerary events has been traditionally based on typological association. However, it is difficult to establish robust associations between archaeological materials recorded on the surface. The ambiguity of these contexts has resulted in generalistic interpretations, described as collective funerary events attributed to the “Eneolithic”, “Chalcolithic” o “Bronze Age”.

In this contribution we present the chronological analysis of the funerary use of caves in the Western Pyrenees based on new and previously published dates obtained of human bone collagen. Chronological models have been elaborated to examine and understand the funerary phenomenon in this region. The results suggest that this phenomenon is recorded since the Mesolithic and it persists until the Bronze Age, although the frequency and characteristics of this funerary use changed during this long time period.

6

**ONE REGION, TWO RITUALS, SAME POPULATIONS? ARCHAEOLOGICAL-ANTHROPOLOGICAL REMARKS ON THE MEDIEVAL BURIALS IN THE ROMANIAN PLAIN**

**Abstract author(s):** Vasile, Gabriel - Ionita, Adrian (“Vasile Pârvan” Institute of Archaeology, Romanian Academy)

**Abstract format:** Oral

The Romanian Plain is a large geographical unit, with silvo-steppe features, located in the southeastern part of Romania. In this region, during the 11th-14th centuries, interesting funerary phenomena were identified, respectively two main funeral horizons, both of them characterized by inhumation. From the first horizon, about 35 burial mounds were investigated, most of which contained

deposits consisting of horse skeletal remains, weapons, military equipment pieces and harnesses. The second funerary custom is represented by several necropolises and groups of flat tombs, totalling about 90 individuals, with an austere inventory, usually ornaments or clothing accessories. In this presentation, we will compare the burials from the two approximately contemporary funerary horizons, located in the same geographical area, but different as a ritual. The chronology of the graves was established both by the traditional analysis of the funeral inventory and some radiocarbon data.

The standard ritual for the first horizon is characterised by: secondary burial in the olds tumuli; rectangular pit; supine position; arms stretched alongside the body; legs stretched; West-East orientation; horse skull and the extremities of the horse’s legs; inventory – bit, knife, arrowheads, iron strike-a-lights, flint, buckle, stirrups, worked bone plates.

The standard ritual for second horizon burials consists of: flat graves; inhumation; rectangular pits; no interior arrangements and no coffin; supine position; arms placed on the chest, abdomen or stretched alongside the body; West-East orientation; a poor or absent inventory.

From the point of view of the funeral standard, the differences are obvious, but the situation is much more complex from an anthropological perspective. We osteologically analysed a sample of about 50 individuals, most of them from necropolises. A series of morphometric, epigenetic and some pathological features were used to compare the two funeral customs.

This work was carried out within the postdoctoral project BioArchMed, funded by UEFISCDI (code: PN-III-P1-1.1-PD-2019-0351).

**HUGGING IN DEATH: A CASE OF AN UNUSUAL GRAVE FROM THE LATE ANTIQUITY SITE OF GRMUŠINA KOSA (SERBIA)**

**Abstract author(s):** Djukic, Ksenija (Laboratory for Anthropology, Faculty of Medicine, Belgrade) - Jončić, Nenad (Faculty of Humanities, University of Primorska) - Milenković, Petar (Laboratory for Anthropology, Institute of Anatomy, Faculty of Medicine, University of Belgrade; Institute of Oncology and Radiology of Serbia - National Cancer Research Center) - Živković, Maja (Institute for the Protection of Cultural Monuments Pancevo) - Nikolić, Veda - Pavlović, Tamara (Laboratory for Anthropology, Institute of Anatomy, Faculty of Medicine, University of Belgrade)

**Abstract format:** Oral

The archaeological site Grmušina Kosa is located on the peripheral of the Bant loess terrace, on the left bank of the one of the old Danube stream, at about 76m above sea level. Located near the village of Skorenovac and 6km away from the city of Kovin, this site geographically belonged to the South Banat District. During the second half of 2019 the site was explored as a part of the protective campaign of archaeological excavations on the route of the main gas pipeline.

Among excavated graves, the grave with skeletons of two children differs from others in unusual position of skeletal remains in situ. The children skeletons in situ laid on the left side in a half-bent position, and it looks younger child embraced the older. Such positioning of children’s skeletal remains represents a unique case in Serbian archeology. They were buried without grave goods, however according to unpublished archaeological records this grave is dated in the Late Antique period, attributed to the Sarmatians.

Anthropological analyses revealed that the older child was 5 to 7 years of age at the moment of death, while youngest child was 2 to 3 years old. Both children showed numerous lesions on the internal and external laminae of their skulls, orbital roofs and long bones. The observed lesions were characterised as traces of metabolic disease. The left humerus of the older child showed signs of a possibly healing greenstick fracture with the most probable differential diagnosis of osteoid osteoma.

The aim of this paper is to discuss the archaeological and bio-anthropological context of this unique grave, and also to present possible reasons for the children’s unusual skeletal positions.

**THE POPULATION GROUP OF CALLE DINAMARCA (VALENCINA DE LA CONCEPCION). A SOCIOCULTURAL AND ARCHAOMETRIC APPROACH**

**Abstract author(s):** Morillo León, José Miguel (Institut für Ur- und Frühgeschichte/Christian-Albrechts-Universität zu Kiel) - Pajuelo Pando, Ana - López Aldana, Pedro (HUM949. Grupo de Investigación Tellus. Prehistoria y Arqueología en el sur de Iberia Departamento de Prehistoria y Arqueología) - Gavilán Zaldúa, Maria - Serrano Castilla, Beatriz - Rojas Aledo, Violeta (Independent)

**Abstract format:** Oral

During the excavation of a plot in the emblematic site of Valencina de la Concepción in 2009, a group of three sepulchres belonging to an early phase of this site were discovered. The archaeological excavation was conducted up to the levels reached by the construction project, uncovering approximately 100 individuals, of which up to a minimum of 68 were recovered. The funerary structures discovered consisted in two hypogea and one funerary pit, and the human remains were extracted with the sediment attached, consolidated using paraloid.

Approximately ten years after, 44 of the skulls were selected to sample them for genetic and isotopic characterization in the framework of the European Project Towards a New European Prehistory.

The chance of studying a coherent social group that undoubtedly shared a sort of link offered relevant perspectives in terms of kinship and social relations within the members of a subsidiary group, in the context of Chalcolithic site characterized by its own social complexity. Even more, during the microexcavation of the skulls prior their sampling, 18 individuals showed diverse grades of traumas.

9 Additionally, in the graphic register of the excavation, it was possible to identify a possible arrow wound in young male. Finally, a hippopotamus ivory tolva idol and a patella shell, together with possible evidences of body decoration were found. Here it is our intention to expose the preliminary social conclusions of our study, awaiting genetic and isotopic results that will conclude with the information about mobility, diet and kinship that will offer an extremely relevant information about an intermediary group in a pristine complex society in the South West of the Iberian Peninsula during the Chalcolithic.

9 **ROMAN FUNERARY PRACTICES IN AUGUSTA EMERITA: DIFFERENTIATED SUBADULT BURIALS FROM 2ND TO 4TH CENTURY (AD)**  
**Abstract author(s):** García-Moreno, Carlos (EcoPast - GI-1553, Faculty of Biology, University of Santiago de Compostela) - Andújar Suárez, Ana (Roman Cities Research Group, Faculty of Geography and History, Complutense University of Madrid) - Murciano-Calles, José - Sabio González, Rafael (National Museum of Roman Art, Mérida)

**Abstract format:** Oral  
The roman city of Augusta Emerita (Mérida, Badajoz), founded in 25 BC., is one of the most important colonies in Hispania as the provincial capital of Lusitania. Although its main necropolises are known, the state of conservation and archaeological works reveal important remains. A funerary area has recently been excavated in recent work carried out in a new area of the National Museum of Roman Art (MNAR). We have studied the 118 individuals buried there between the 2nd and 4th centuries AD. This study has consisted, on the one hand, in registering the characteristics of the tombs and the composition of the grave goods. On the other hand, in the detailed anthropological analysis of individuals to estimate their age. Among these, 33% correspond to subadult individuals (<20 years). The large number of cases is very significant compared to other burial areas of the same period in Hispania. In addition, among the infant graves, different ritual practices applied to these individuals have been detected. These data require a reading of the possible causes that motivated this concentration of individuals treated ritually in a heterogeneous way. Among these specific rituals, the finding of remains of lime in two of the tombs stands out. This intentional practice is not widely documented at this time for any age group. In order to explain this and interpret these practices, we have contrasted the data from the study funerary area with those from others about the same period and territory. Stable isotope analyzes (paleodiet and mobility) and paleopathological analyzes are important in our research in process on these subadult individuals. On the other hand, archeometric analyzes on the aforementioned lime remains are essential. With all these data, we can get closer to the way of life of these small inhabitants of the city.

10 **IDENTITY AND MORTALITY: RECONSTRUCTING ORIGINS OF A MEDIEVAL ISLAMIC POPULATION IN SANTARÉM, PORTUGAL THROUGH AN ISOTOPIC STUDY OF SKELETAL REMAINS**  
**Abstract author(s):** MacRoberts, Rebecca (HERCULES laboratory- University of Evora) - Teixeira, João (Australian Centre for Ancient DNA, School of Biological Sciences, The University of Adelaide) - Liberato, Marco (Centro de Estudos de Arqueologia, Artes e Ciências de Património) - Valente, Maria João (Faculty of Human and Social Sciences, University of Algarve) - Relvado, Cláudia (Interdisciplinary Center for Archaeology and Evolution of Human Behaviour, University of Algarve) - Barrocas Dias, Cristina (HERCULES Laboratory, University of Évora; School of Technology Sciences, Department of Chemistry, University of Évora) - Matos Fernandes, Teresa (Research Centre for Anthropology and Health - CIAS, University of Coimbra; School of Technology Sciences, Department of Biology, University of Évora) - Barros, Filomena - Vasconcelos Vilar, Herminia (School of Social Sciences- CIDEHUS, University of Évora) - Maurer, Anne-France (HERCULES Laboratory, University of Évora)

**Abstract format:** Oral  
The excavation of the site of Avenida 5 de Outubro, Santarém, Portugal uncovered a necropolis containing the remains of the Islamic population who occupied the city from the 8th/9th to the 11th century. There is evidence of two waves of Islamic settlement in Santarém, a theory suggested by the presence of two distinct grave orientations in the site, in some cases one superimposing the other. A previous dietary study of the Santarém population using carbon and nitrogen stable isotopes from the bone collagen of selected individuals (presented in EAA 2020 Virtual Meeting) indicated less variable diets in the apparent earlier population than the later one. Using these results, along with archaeological evidence as a guideline, the mobility of medieval Santarém Muslims has been subsequently assessed by measuring sulphur stable isotopes from bone collagen and strontium radiogenic isotopes from tooth enamel, selected from individuals with both earlier and later grave orientations. Results of this research will provide clarity to the archaeological theory that the earlier graves belonged to the initial post-conquest Islamic population who migrated to Iberia from Africa. Additionally, we sequenced complete mitochondrial genomes for six individuals in order to further disentangle their genetic ancestry and geographic origins. The funerary practices of this population and their changes over time (i.e. grave orientation), mirror the cultural and religious identity of the Islamic population adapting to life in the Iberian peninsula through generations. The origins and identity of the population will be supported by the geochemical data obtained from their skeletal remains. This research is part of the project "TRANSCULTURAL (POCI-01-0145-FEDER-031599)".

11 **CHILDHOOD, DIET AND RELIGION: THE STUDY OF BREASTFEEDING AND WEANING PATTERNS IN TWO MEDIEVAL PORTUGUESE POPULATIONS**  
**Abstract author(s):** Relvado, Cláudia (Interdisciplinary Center for Archaeology and Evolution of Human Behaviour, University of Algarve) - MacRoberts, Rebecca (HERCULES Laboratory, University of Évora) - Fernandes, Teresa (Research Center in Anthropology and Health, University of Coimbra; School of Science and Technology, Department of Biology, University of Évora) - Umbelino, Cláudia (Research Center in Anthropology and Health, University of Coimbra; Department of Life Sciences, University of Coimbra) - Dias, Cristina (HERCULES Laboratory, University of Évora; School of Science and Technology, Department of Chemistry, University of Évora) - Maurer, Anne-France (HERCULES Laboratory, University of Évora)

**Abstract format:** Oral  
Children's diet, namely the Breastfeeding and Weaning Patterns (BWP), have a strong impact on survival of non-adults and health during adulthood. Analysis of  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of skeletons can help in estimating BWP of archaeological populations, which depend on cultural factors, and which may help in understanding the general health conditions prevailing in the past. This study analyses bone collagen stable isotope data ( $\delta^{13}\text{C}$ ,  $\delta^{15}\text{N}$ ) from 38 non-adults from the Medieval Christian necropolis of São Miguel de Odrinhas (SMO) (11th-15th centuries) and 27 non-adults from one Medieval Islamic necropolis of Santarém (9th -12th centuries). Data obtained from children are compared to those from female adults and interpreted regarding environmental baseline (fauna) for both sites. This study is part of the TRANSCULTURAL project (POCI-01-0145-FEDER-031599). Demographically, the Islamic necropolis presents a larger proportion of younger individuals (<3 years) as opposed to the Christian necropolis. BWP are also quite different between both necropolises. The Islamic individuals of 0-3 years old show the expected increase in  $\delta^{15}\text{N}$  values related to breastfeeding. Some of those non-adults display an increase in  $\delta^{13}\text{C}$  values in relation to the adult average higher than expected (between 1‰ and 2.8‰), which may be related to different female diet during pregnancy and breastfeeding and/or to the addition of supplementary food products to the children's diet. In the Christian necropolis the increase in  $\delta^{15}\text{N}$  values is not so visible, and some individuals seem not to have been breastfed at all. Weaning was complete at the age of four in both case studies. Also, in these necropolises, the older non-adults yield slightly lower  $\delta^{15}\text{N}$  values than adults, which may be related to different diets or to their own growth. BWP and diet of children of these Medieval communities are very different, which may be related to different socio-cultural, socio-economic, and geographical factors.

A. **STABLE CARBON AND NITROGEN ISOTOPES OF SKELETAL REMAINS AS EVIDENCE OF DIET IN MEDIEVAL SANTARÉM (PORTUGAL)**  
**Abstract author(s):** Leite, Adriana (Research Centre for Anthropology and Health, Department of Life Sciences, University of Coimbra) - Maurer, Anne-France (HERCULES Laboratory, Chemistry Department, University of Évora) - Relvado, Cláudia - Umbelino, Cláudia (ICArEHb, University of Algarve; Research Centre for Anthropology and Health, Department of Life Sciences, University of Coimbra) - Silva, Ana Maria (Research Centre for Anthropology and Health, Department of Life Sciences, University of Coimbra; UNIARQ, University of Lisbon; CEF, Department of Life Sciences, University of Coimbra)

**Abstract format:** Poster  
When applied to the study of ancient human populations, stable isotope analysis can be considered as a tool used to examine past ways of life, such as diet, migration, breastfeeding and weaning strategies, socioeconomic and biological restraints. Due to its geographic and strategic position, Santarém was considered one of the most important cities of Portugal during the Middle Age. This chronological period is of great relevance because of the Christian conquest of Santarém, which induced structural and socioeconomic changes that may potentially reflect a differential access to the available food. This study aims at reconstructing the diet of medieval individuals unearthed from the Necropolis of Rua dos Barcos, Ribeira de Santarém (Santarém), and at exploring possible sex and age-at-death differences. Anthropological, historical, and archaeological evidence suggest a Christian occupation of the site. Carbon ( $\delta^{13}\text{C}$ ) and nitrogen ( $\delta^{15}\text{N}$ ) isotope ratios were measured in bone collagen of 27 individuals, 15 non-adults and 12 adults. Historic evidence states that the Portuguese medieval diet consisted of staple cereals and wine supplemented with meat, aquatic resources, and vegetables. In line with these historical sources,  $\delta^{13}\text{C}$  (mean=  $-16.6\text{‰} \pm 1.9$ ; n=24) and  $\delta^{15}\text{N}$  (mean=  $11.0\text{‰} \pm 0.8$ ; n=24) values of human bone collagen suggest that the staple diet was predominantly based on a consumption of C3 plants and animal protein with a possible input of C4 plants and/or aquatic protein intake (e.g. low-trophic level fish). No age-at-death and sex statistic differences were observed in human bone collagen  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values. Representing the first palaeodietary study of Ribeira de Santarém, this research increases our knowledge of dietary habits in Medieval Portugal.

347 **PUBLIC AND COMMUNITY ARCHAEOLOGY IN A (POST-)COVID LANDSCAPE [PUBLIC ARCHAEOLOGY]**  
**Theme:** 3. The new normality of heritage management and museums in post-Covid times  
**Organisers:** Westmont, V. Camille (University of the South) - Benetti, Francesca (Historic Environment Forum)  
**Format:** Session with presentation of 6 slides in 6 minutes

Public and Community Archaeology practices often involve direct contact with the public, something strongly discouraged during the COVID-19 pandemic. Changes brought about by COVID-19 have affected heritage stakeholders in a variety of ways. As volun-

teering and in-person meetings ceased, heritage organisations were forced to find other ways to connect with the public, leading many of them to use the digital environment in new ways. While many heritage organisations have struggled with closures and quarantines, the pandemic has provided some communities with greater opportunities to enjoy their local heritage due to the decline in tourism. Moreover, the duty to work from home and avoid transport and travel has encouraged people to take more walks in their local area, discovering their place and connecting to the landscape more deeply. As COVID-19 had and continues to have a huge impact on the entire archaeological and heritage sector, this session aims to explore: How have experiences in Public and Community Archaeology adapted to the new conditions? How can Public and Community Archaeology projects kickstart the recovery? What are the medium- to long-term impacts the pandemic is expected to have on the activities and projects? What challenges did you have to face and how did you minimise the risks? What lessons have you learned and which you will keep in a (post-)COVID-19 world?

## ABSTRACTS:

### 1 RECHARGING BRITISH ARCHAEOLOGY: CREATING NEW OPPORTUNITIES FOR PARTICIPATION

**Abstract author(s):** Corkill, Claire - Redfern, Neil (Council for British Archaeology)

**Abstract format:** Oral

Local archaeology groups and societies across the UK provided valuable opportunities for the public to participate in archaeology, sharing knowledge, skills and creating opportunities for people to explore the stories of their place and deepen their connections with their communities. Covid-19 has had a significant impact and with the inability to meet in person many groups have found it challenging to continue to engage with their members.

Through the Historic England funded Recharging British Archaeology project, the CBA has provided support for these groups throughout the pandemic to help them overcome some of the challenges they have faced, celebrate their successes and provide training so they feel better equipped with the skills and confidence to embrace new methods of delivery. By listening to and working with these groups we have identified a range of opportunities to help them become more resilient and capable of creating an even greater impact on their communities in the future. In our 6 minutes we will set out the key lessons we have learnt from this work and how we will be implementing them moving forwards.

### 2 REFLECTIONS ON RUNNING COMMUNITY ARCHAEOLOGY PROJECTS IN SOUTH EAST ENGLAND DURING COVID 19

**Abstract author(s):** Mayfield, Andrew (Kent County Council) - Adams, Sophia (University of Glasgow)

**Abstract format:** Oral

At the beginning of 2020 we had a busy programme of community archaeology planned for the year. Once the pandemic struck, we had to postpone all in person activities and devise new ways of engaging with the public and volunteers. This involved creating remote activities, strengthening methods of communication and planning how we could safely deliver community archaeology activities post lockdown. Each of the three distinct projects we were working on had their own set of challenges from connecting with new volunteers to managing the expectations of regular participants.

Through my voluntary role leading the local Young Archaeologists Club (YAC), I also worked with our volunteer team to find creative ways to engage children with archaeology at a time when so much of their learning had shifted online. This presentation will reflect on 2020, the issues we faced with projects in Kent and the lessons we learned. As we look forward to a post-Covid world, how can we do things differently? What lessons can we learn from our experience of remote community archaeology in 2020?

### 3 THE EFFECTS OF THE COVID PANDEMIC ON ARCHAEOLOGICAL SITES MANAGED WITH A BOTTOM UP APPROACH IN NAPLES, ITALY

**Abstract author(s):** De Vivo, Caterina (Centro Studi Interdisciplinari Gaiola Onlus - Progetto Museo)

**Abstract format:** Oral

In the last few years many private-public partnerships have been established in Naples, Italy, with a bottom up approach in order to manage archaeological sites and make them more accessible to the public. Many of these cases are considered national best practices and models to re-think the State approach to the management of cultural heritage sites. These sites have been strongly impacted by the COVID-19 crisis and many limits of the management model have been recognized. In fact, the pandemic made clear how most of these sites cannot survive without the tourism industry.

Moreover, the crisis made clear how, without any public fund, the private organizations managing archaeological sites with a bottom-up approach cannot deal with the responsibility of taking care of the sites/museums.

This papers is aimed at analyzing the problems that the pandemic raised in a wide perspective to underline what lessons we have learned and what should be changed to make the system more sustainable.

### 4 WAYS OF TELLING STORIES OUTSIDE DURING LOCKDOWN

**Abstract author(s):** Paulsen, Charlotte (Museum Skanderborg)

**Abstract format:** Oral

During lockdown of Denmark in the spring of 2020, the citizens of Skanderborg as in many other places turned to walks in their local area. Museum Skanderborg had to cancel numeral sold out guided tours, as groups were not allowed. Instead, the museum developed others ways of telling outside stories. This paper presents two examples as ideas for others to follow on ways of telling stories in Covid-19 and post Covid-19 times.

In the city of Skanderborg, a cooperation with the Municipality of Skanderborg resulted in 10 wooden benches along the main shopping road with historic photos, and a website where you could read about the people on the photos. The benches provided sitting spots for walkers and decoration in the street as well as a good story along the way. The benches were a re-use from another event. The only cost was the new pictures and a truck to put them in the streets. The benches were only a temporary concept and were removed before winter, but the museum and the municipality are using the knowledge of the project in further development of the city center.

In a forest and close to the city, we also wanted to provide stories for walkers. As we did not want people to walk around looking at their phones instead of nature, we did not want to make it digital. There was not budget to make proper signposts, but 20 old fashioned laminated posters were tied around big trees for people to read along their walks. People responded positively to the posters and went looking for them all. The posters were taken down in the autumn, as the string and the posters were worn out after the summer. The Municipality of Skanderborg has now decided to make the posters in to proper signposts.

### 5 ARCHAEOLOGY AT A PINCH: HOW A COVID-DRIVEN COLLABORATION IS FUELING A SUSTAINABLE COMMUNITY ARCHAEOLOGY PROJECT IN TENNESSEE, USA

**Abstract author(s):** Westmont, V. Camille (University of the South)

**Abstract format:** Oral

After the University of the South's (Tennessee, USA) undergraduate archaeology field methods course in summer 2020 was cancelled due to COVID, two archaeologists decided to carry out excavations on their own. However, we were soon inundated with requests from regional organizations seeking outdoor opportunities for local youths. Given low COVID case counts in the surrounding area and the rural nature of the site, we elected to work with the AmeriCorps VISTA program to provide job opportunities for five local youths (ages 18-22) during summer 2020. Strict COVID policies were implemented that have helped us redefine how we will do in-person public engagement in the future. Additionally, although archaeology had never before been part of the VISTA program's job placement program, after the success of the summer work, we have developed an on-going collaborative relationship with the organization, including providing digital opportunities for as many as 14 local youths during fall 2020 and winter 2021. In this case, COVID opened doors to new collaborations and opportunities that neither party had previously considered.

### 6 HOW TO DO COMMUNITY ARCHAEOLOGY WITHOUT COMMUNITY? EXPERIENCES FROM RURAL GALICIA (SPAIN)

**Abstract author(s):** Ayán, Xurxo (NOVA University of Lisbon)

**Abstract format:** Oral

Since 2016 we have been developing Community Archaeology projects in the rural region of the Ribeira Sacra in Galicia (Spain). On March 13, 2020, the government of Spain decreed the first total confinement of the population to combat the COVID-19 pandemic. This communication aims to show how our work team has adapted to the different stages that we have experienced since then, between the successive waves: total confinement (March-June 2020), de-escalation between the first and second waves and semi-confinement (since December 2020). The strategies adopted have allowed us to continue with the excavation of two emblematic archaeological sites (San Lourenzo and Os Conventos) at a time when the declaration of the Ribeira Sacra as a World Heritage Site by UNESCO was decided. We will try to show how a committed archaeology, flexible and willing to take risks (always obeying the health authorities) has become an effective tool to overcome the feeling of ruin installed in people and to generate optimism within this new reality full of uncertainties. The examples of the archaeological project of the San Lourenzo hillforts and 'Adegas da Memoria' can inspire other colleagues to seek alternatives and not paralyze ongoing projects. After years of effort, we all know that a hiatus in an Community Archaeology project can lead to its final disappearance. COVID-19, like other pests of the past, will not destroy either these peasant communities or the community of archaeologists.

### 7 THE BEST-LAID PLANS OF MICE AND MEN – ADAPTING THE ARCHAEOLOGICAL SIDE OF THE LIVE PROJECT DURING THE COVID-19 PANDEMIC

**Abstract author(s):** Moeller, Katharina (Prifysgol Bangor University)

**Abstract format:** Oral

The Llŷn IVeragh Eco-museums (LIVE) project was designed to enable coastal communities to promote their natural and cultural assets, as well as to create opportunities for sustainable tourism. An important aspect of LIVE is the generation of new knowledge in cooperation with these communities to support them in engaging more deeply with their local environment and culture. Where the

archaeological heritage on the Llŷn peninsula is concerned, this was supposed to be done through Bangor University’s excavation at the late Bronze Age/Iron Age double ringwork enclosure at Meillionydd, which has always welcomed volunteers from all over the world. However, due to the COVID-19 pandemic, neither the excavation nor the associated outreach activities could take place in 2020 and 2021. Instead, alternative means to reach the public were developed in line with the strict COVID guidelines in Wales. This includes a series of digital and non-digital resources to enable the public to learn about the archaeological heritage of the Llŷn, as well as socially-distanced activities and virtual site visits. This paper will look at the changes the archaeological aspect of the project had to undergo to be deliverable during the pandemic and the future plans for the time post-COVID.

8 VIRTUAL HERITAGE AND WELLBEING

**Abstract author(s):** Sayer, Faye - Luck, Amy (Manchester Metropolitan University)

**Abstract format:** Oral

The ‘Virtual Heritage and Wellbeing’ pilot project was launched in response to the COVID pandemic and the negative impact it had on global wellbeing. Closures and social distancing measures due to the pandemic resulted in heritage organisations increasing their online presence and a 40 per cent upsurge in online visits. Virtual heritage became the main method by which the public engaged, learnt, and connected with their past, and provides a potentially cost effective, sustainable, resilient, and safe way for heritage organisations to engage with audiences.

This project, supported by heritage organisations and the What Works Centre for Wellbeing, applied public heath accredited methods, including Positive and Negative Affect Schedule and the Modified Wellbeing Scale to measure the impact of virtual heritage on user wellbeing. Results demonstrate that engagement with virtual heritage had a positive impact on user wellbeing. This study provides evidence for heritage organisations to consider virtual strategies as sustainable and resilient mechanism to engage with audiences and have a social impact.

9 TANGIBLE ARCHAEOLOGY IN THE DIGITAL ENVIRONMENT: EXPERIENCES IN AN ARCHAEOLOGICAL MUSEUM

**Abstract author(s):** Aalto, Ilari (University of Turku; Aboa Vetus Ars Nova Museum)

**Abstract format:** Oral

Aboa Vetus Ars Nova Museum (Turku, Finland) houses archaeological remains of several medieval stone houses that were excavated in the 1990s. Since its opening, Aboa Vetus Ars Nova has had a strong emphasis on the museum pedagogy: audience engagement and educational programs. The museum has an especially strong expertise in organising educational activities and participatory programmes in the field of mediating archaeological heritage. The museum continues archaeological excavations in the museum area regularly. Conducting archaeological research and sharing and applying its results form the basis for the museum’s participatory activities.

Medieval ruins form a tangible historical environment, and the COVID-19 pandemic has forced the museum to find new ways of translating physical experiences to the digital environment. Features such as three-dimensionality, weight, texture, surface temperature or even smell are all part of the so-called “sensory engagement” with a physical object. Also being physically present and spending time in the museum spaces or archaeological sites is an empowering experience for the visitors.

These aspects are often missing when engaging with museum objects or archaeological topics in a digital space. This paper discusses some of the ways used to give audiences a fulfilling learning experience using archaeology as a starting point in the online environment.

348 DERIVATIVES OF THEIR MEN? ALTERNATIVES TO THE “WOMAN PROBLEM” IN MORTUARY ARCHAEOLOGY [AGE]

**Theme:** 6. Material culture studies and societies

**Organisers:** Stanton, Emily (University of Wisconsin-Milwaukee) - Pope, Rachel (University of Liverpool)

**Format:** Regular session

During a vigil in honor of the late Ruth Bader Ginsburg, Judge Diane Goodstein of South Carolina noted that the “Notorious RBG” was a dauntless champion of women’s rights and gender parity in the United States and one of the main reasons that “today, women are no longer derivatives of the men in their lives.” While this idea has gained traction in the present day, many archaeological interpretations of women’s lives in the past tend to be androcentric by default.

For example, the elite women of late Hallstatt Central Europe were often buried with splendid sets of personal ornamentation such as ring ornaments, hairpins of bronze or gold, and belt ensembles decorated with thousands of intricate bronze staples. A persistent interpretive model for these items is that they represented the wealth of the woman’s husband; she wore these ornaments as a walking display of the economic status of the men in her life. This perspective presents the great women of the past as mere derivatives of men, with little or no agency. The work of Judith Butler (1990; 1993) refers to this idea as the Woman Problem, while Fraser (1988:107) dubbed it the Appendage Syndrome which views women “as an extension or prolongation of the rule of a particular great man.”

But why must this be the case? The idea that powerful women in prehistoric societies were an anomaly reflects a biased over-generalization of the complexities of women’s lives in the past (Nelson 2004, 2006). This session will explore the issues inherent in the Appendage Syndrome or Woman Problem from a pan-European archaeological perspective while suggesting possible alternatives to this interpretative lens. We welcome papers that examine this issue across multiple time periods and geographic regions, especially those with a focus on gender and mortuary archaeology.

ABSTRACTS:

1 WOMAN OF THE HOUSE? FUNERARY DRESS AND FEMININE POWER IN IRON AGE CENTRAL ITALY

**Abstract author(s):** Prew, George (University of Glasgow)

**Abstract format:** Oral

Theories of how urbanism occurred across Iron Age Italy have traditionally revolved around the concept of elite classes comprising masculine leaders. Tombs, particularly richly-furnished ‘princely’ tombs of the eighth and seventh centuries BCE, have provided the main material evidence for these elevated men. However, scholarship has focused disproportionately on this richest subset of tombs and their occupants (often assumed male by default), skewing understandings of power and gender in ancient Italic communities and under-representing the role and power of women as separate from their male relations. Through new sensory and material analyses of around 1,400 published graves from sites across central Italy (Osteria dell’Osa in Latium; Fossa and Bazzano in the Abruzzo), this paper presents new insights into gender and the power of women within Iron Age central Italic societies, as well as frameworks for gender study in tombs throughout history and prehistory.

Sensory, material, categorical, and associative analyses of dressed bodies in graves provide multiple lenses through which to build a composite picture of the deceased, their constructed identity in the grave, and the communities in which they lived. Applying osteological sex estimations to the patterns that emerge from these graves then allows a picture to emerge of the place of women in early Italy not as an adjunct to men, and, through intersectional study of apparent age, social class, and other reconstructable identity markers, not only as women. By applying these methods to cemeteries across early Iron Age central Italy, new conclusions and greater nuance can emerge beyond narratives of male rulers, and of women valued primarily for their ability to produce male rulers. Osteologically-visible sex then appears, contrary to prevailing narratives in ancient Italic scholarship, as an integral part of funerary identity, but without any imposed gendered hierarchy.

2 WOMEN IN THE MACEDONIAN KINGDOM DURING THE 6TH C. BCE: BOTTOM-UP VS TOP-DOWN VIEWS OF THE FUNERARY EVIDENCE

**Abstract author(s):** Saripanidi, Vasiliki (Université libre de Bruxelles)

**Abstract format:** Oral

Macedonian necropoleis from the 6th c. BCE have yielded a series of lavishly equipped female burials that find no parallels in the archaic Greek world. Systematically overlooking their archaeological context, interpretations of these burials have relied on a preconceived dichotomy between male/public/power and female/domestic/subordination. Thus, those grave goods that evoke dressing and grooming practices, such as jewelry and perfume flasks, have been considered as “typically female” and assigned a biographic function. On the other hand, artifacts that allude to the public sphere, such as feasting accessories and wagon models, have been either completely disassociated from the biographies of the deceased or identified as insignia of the only imaginable authoritative female role, that of a priestess. In any case, the high status ascribed to certain women upon their death, and even their assumed right to priesthood in life, have been understood as mere reflections of the status of the powerful fathers and husbands of these women. Following a reverse, bottom-up, approach, this paper will demonstrate that, while the aforementioned interpretations may already raise suspicions on theoretical grounds, they actually find little support in the archaeological record. It will be further shown that, although the Macedonian funerary evidence from that period does, indeed, testify to certain gender distinctions, at the same time it suggests that such distinctions did not permeate all social action spheres nor were they always underlain by male-dominated hierarchical relations. Stressing that Macedonian burials attest to more pronounced hierarchies within rather than between gender groups, the paper will finally argue that, within the archaic Macedonian society, access to networks of power was neither exclusively nor always primarily conditioned by perceptions of gender.

3 BRAZEN WOMEN? RECONSIDERING INTERPRETATION OF MALE AND FEMALE ELITE BURIALS (LATE BRONZE AGE- LA TÈNE B, IN NORTH ALPINE COMPLEX)

**Abstract author(s):** Tremeaud, Caroline (TRAJECTOIRES UMR 8215; Cellule Archéologique des Ardennes)

**Abstract format:** Oral

In February 1953, the rich grave of “The Lady of Vix” was excavated; the funeral deposit is particularly impressive, including a golden torc, and bronze and silver vessels (including the famous krater) imported from the Italian and Greek world. But the grave contained no weapons, which lead to fifty years of papers debating the sex and status of the deceased; the conclusive identification of female sex was only established in the early 2000s.

In October 2014, the excavation of another rich burial at the site of Lavau revealed several similarities: another gold torque, bronze vessels, and imported goods. As with analysis of the Vix burial 61 years prior, the question of the deceased’s sex was raised. Osteological analysis concluded that the individual was male, thus removing the doubt that this individual was high-ranking member of the social elite, “a prince”.

Despite 60 years of research in archaeology, including gendered issues in interpretation, the question of the sex is always raised in the same way:

- a rich female burial raises the issue of her status, whereas a rich male burial is thought to be that of an elite member, probably a political chief, a so-called “Celtic prince”
- a typical starting point in interpreting the burial as male or female is whether the burial contains weapons.

However, current analysis (Trémeaud 2014, 2018) based on a corpus of more than 800 elite graves in the North Alpine Complex, from late Bronze Age to La Tène B, has characterized the elite burial phenomenon and highlighted the significance of feminine burials. The presentation of this study and the results will pose challenges to the traditional interpretation of women’s position among the elite. The aim of this presentation is to offer new interpretations on both male and female elite burials.

#### 4 DIVERSITY OF MALE IDENTITIES IN EARLY AND MIDDLE LA TÈNE CEMETERIES

**Abstract author(s):** Ramsel, Peter (University of Vienna, Institute of Prehistory and Historical Archaeology)

**Abstract format:** Oral

Discourse on male identities in the Iron Age has hitherto been dominated by thoughts about warrior identity. However, only a fraction of male bodies are laid out as warriors in their graves, prompting questions such as: What roles did men play in society? What roles did men without weapons play in “warrior societies”? In a 2016-2018 SASPRO-project “Male identities in La Tène period cemeteries in the middle danube area in Nitra, Slovakia, I studied a large corpus of La Tène period graves and cemeteries in the area of Slovakia, east Austria, and Moravia to attempt and answer these questions.

In this paper I seek evidence of different subgroups within the large group of graves with anthropologically male skeletons, which does not automatically mean that these individuals had been seen as “male” in their own times. First of all, different life-stage identities shall be analyzed – namely, “boy identity”, “adult identity”, and “old man identity.” Additionally, a number of “special identities” have emerged in the last few years, such as males with “female” rings or costume or females with weapons, also suggest the idea of multiple male identities. Other special identities can also be observed in La Tène period cemeteries, including “Druid identities,” “craftsmen identities” and “poor man identities.” Above all, past societies were by no means as simple as schoolbooks sometimes portray. Thus, the group of anthropologically male remains includes “special identities” that cross the borders of standard interpretive models. Male skeletons with otherwise typically “female” markers like special jewellery or “male” markers that are used in a non-standard way suggest other interpretive models beyond the simple male/female dichotomy. The field of gender archaeology has begun to exert a very important impact on our scientific research and the ways in which we envision people in the past.

#### 5 THE ROLE OF WOMEN IN THE AVAR EMPIRE (CA. 568-800 AD): A REVIEW

**Abstract author(s):** Bühler, Birgit (Vienna Institute for Archaeological Science - VIAS, University of Vienna)

**Abstract format:** Oral

The Avars, equestrian nomads of predominantly Central and Inner Asian origin, were present in eastern Central Europe from the year 568 to around 800 AD. The Avar male elite, in particular in the 6th-7th century AD, were renowned for their skills in mounted combat. However, the role of women in Avar society is a topic that merits further research: In general, Avar material culture, predominantly grave goods, indicates that the daily life of women in Avar communities in the Carpathian Basin tended to focus on the domestic sphere, with textile-production activities such as spinning and sewing documented by the grave goods. However, there are a small number of elite “female equestrian graves” (female burials including horses) from the Avar Period: Although no weapons occur in these burials, grave goods associated with domestic activities such as spinning and sewing are usually missing from female equestrian graves. Due to a lack of written sources from within the Avar Empire, we have no information about many aspects of life in the Avar period. Historical records concerning the Avar Empire are all “external”, written by historiographers from neighbouring cultures, such as Byzantium, China or the Frankish Empire. The scarcity of relevant historical sources can make it difficult for archaeologists to decipher “the cultural code” inherent in Avar burials. However, the historical record of other equestrian nomadic cultures, such as the Mongolian Empire in the Later Medieval Period, may be helpful in providing analogies for gender roles in Avar society. Furthermore, bioarchaeological research can assist the interpretation of Avar burials, by providing information on activity patterns, lifestyle and general health. The aim of this paper is to review the state of research on the role of women in the Avar Empire (568-800 AD) and to suggest future directions for interdisciplinary research on this topic.

#### 6 CHANGING PERSPECTIVES – OVERCOMING ANDROCENTRISM AND THE « WOMAN PROBLEM » IN FRENCH MORTUARY ARCHAEOLOGY OF THE EARLY MIDDLE AGES

**Abstract author(s):** Clara, Blanchard (Paris I - Arscan)

**Abstract format:** Oral

In the late twentieth and early twenty-first century, French archaeological research on the early Middle Ages has not engaged deeply with the insights established in gender studies. The perspective of French archaeologists has been predominantly androcentric and male-focused; it is rare that gender stereotypes of the dead are questioned. It is assumed, for instance, that there was a strong dichotomy between the “male” and “female” funerary artefacts unearthed in early medieval graves. The study of women, mostly thought of as ornamented representatives of the power and wealth of male warriors, has particularly suffered from those expectations, and insufficient work has been done on the characteristics of female identity. However, by introducing new methodology and approaches through the prism of gender and by moving beyond the traditionally gendered typology of objects, the symbolic application of artefacts and the diversity of the expression of female attributes can be reevaluated. Benefitting from a rich funerary material culture, more reliable determinations of sex via osteology, the problematization of the gendered nature of traditional assumptions in early medieval archaeology, and the most recent approaches in gender theory, we will soon understand much more, no doubt, about the varied incarnations of female experience in the early Middle Ages in France.

#### 7 HONDURAN FIGURINES FROM A NON-BINARY PERSPECTIVE: INTERSECTIONAL AND INTERSUBJECTIVE IDENTITIES OF OTHER-THAN-HUMAN PERSONS

**Abstract author(s):** Hendon, Julia (Gettysburg College)

**Abstract format:** Oral

During the 6th to 10th centuries CE, people living in Honduras developed working with clay to a high level of artistry. Among the examples of this engagement with clay are three-dimensional figures of varying sizes. Sometimes designed to be musical instruments, Honduran figurines of this era are notable for the variety of beings depicted. These beings may combine features of humans, animals, or plants into hybrid beings. They are dressed and adorned, wearing jewelry, clothing, and accoutrements that are assumed to reflect the ways that the people who made and used them dressed themselves. Archaeological research has found that these figurines played important roles in ritual and ceremonies associated with households and communities. These roles included being born (or made), participating in rituals, moving from one locality to another, and being buried (disposed of), often in pieces. Figurines are other-than-human persons, providing a glimpse into the ways that people of the time interacted with objects. Gender seems to be an important part of the imagery of these figures and much research to date has focused on this aspect of the human-style figurines. Less attention has been paid to the non-human or hybrid creatures even though at least some of these may have been gendered as well. This paper explores what happens if we consider gender from a non-binary perspective while also incorporating as wide a range as possible of the beings depicted. Rather than starting by dividing human figurines (and some animals) into two unexamined categories of male and female, this paper considers the range of possible identities and meanings that emerge when gender is actively interrogated rather than taken for granted. The paper proposes that looking at identity as both intersectional and intersubjective provides a more nuanced understanding of gender in these societies.

#### 8 THE FICTIONAL ARCHAEOLOGIST: FEMALE EDITION

**Abstract author(s):** Annis, Karissa (University of Wisconsin-Milwaukee)

**Abstract format:** Oral

Women in archaeology have historically been underrepresented in most, if not all, aspects of archaeological work. It has been a male dominated field for most of its existence, and it is only recently beginning to change. The presence of women in representations of archaeology have fared little better. This presentation focuses on the presence or lack thereof of women in fictional archaeological representations. In the past, this was often limited to being a side character to the male protagonist, such as Elsa Schneider in Indiana Jones. Other times, this was a character such as Lara Croft, who was a rare female lead but often overly sexualized for the male gaze. This presentation will compare these past examples to recent fictional female archaeologists to determine whether or not the representations are becoming more popular and diverse, or whether they remain sparse and stereotypical. Moreover, there will be a discussion as to whether these women are, in fact, derivatives of or written for men, or whether these women stand on their own as characters and as women. This presentation will also endeavor to examine what this means for the field as a whole, as popular representations often reflect or inform academic’s perceptions as well.

KEEPING APART AND COMING TOGETHER: MOBILITY RESTRICTIONS AND CONFINEMENT AS HEALTH PRACTICES IN A LONGUE DURÉE PERSPECTIVE

**Theme:** 2. Pandemics and climate change: responses to global challenges

**Organisers:** Cianciosi, Alessandra - Zaneri, Taylor (University of Amsterdam) - Pazienza, Annamaria (Ca’ Foscari University of Venice)

**Format:** Regular session

This session focuses on two key questions: how did past societies, especially after Antiquity, use strategies of mobility and spatial knowledge to overcome or to prevent climatic, environmental and epidemic catastrophes? How did human actors link these strategies to the promotion of human, animal, and environmental health? Pre-modern communities have always faced dramatic and sometimes severe crises, such as environmental devastation, failure of crops, pollution, the proliferation of disease in both humans, animals, and non-animals. Archaeology and history tell us that these crises have prompted shifts in the ways that people inhabited their settlements and surrounding landscapes. Mitigation of negative impacts and pre-emption upon of these events by careful planning often required changes grounded in movement and in use of space. Thus mobility and spatial thinking were connected to maintaining and fostering health and safety, triggering social and cultural changes of short or long duration, not only from a reactive but also from a proactive perspective. Such actions could include physically isolating or creating barriers to sick individuals, moving communities from resource poor locations to resource dense locations, constructing specific zones or facilities for waste removal, or conversely regulating or protecting sources of water and food. Therefore promoting health required the ability to recognize the risks contained or intrinsic to a place, and to implement solutions which removed, separated or mitigated the potentially harming matter.

The main aim of this session is to bring together scholars who can build on their chronological, geographical as well as disciplinary expertise to examine common patterns and dissimilarities in the ways that different societies coped with negative impacts of disease and climatic crises, especially through changes in mobility and in space organization. We particularly welcome interdisciplinary papers which involve the integration of different scientific methods (archaeology, history of science, anthropology, climatology).

ABSTRACTS:

1

VILLA ESTATE AGRICULTURE AND MALARIA IN ROMAN CENTRAL ITALY: A DIACHRONIC STUDY OF AN UNFOLDING ENTANGLEMENT

**Abstract author(s):** Pickel, David (Stanford University)

**Abstract format:** Oral

In describing the risks faced by Roman farmers, the agronomist Varro explains that on pestilential land “where the reckoning is with death, not only is profit uncertain, but also the farmer’s life.” What follows this statement, however, is perhaps more revealing. Varro continues: “And yet this risk can be lessened by science. While granting it is not in our power but in that of nature, as the healthiness of land is drawn from climate and soil, still it depends greatly on us, because we can, by care, lessen this harm” (de Re Rustica, 1.4.4). One of the most consequential pestilences which Romans faced was malaria. Wherever prevalent malaria increases mortality and morbidity rates, depresses economic growth, and reinforces inequalities. It is therefore surprising that little work has been done regarding malaria’s impact on and interaction with individual Romans and Roman society overall, especially considering that a wealth of evidence makes clear that the disease was present across the ancient Mediterranean. In this presentation I take seriously Varro’s words to better understand malaria’s epidemiology in Roman central Italy – it’s spatial and temporal dimensions, and the agents, processes, and ideas caught up in its transmission. Inspired by the tenets of entanglement theory, I study how the materiality of villa estate agricultural infrastructure, in tandem with the environment and human practice, affected the risk of malaria’s transmission through time. Through this analysis it becomes clear that the Romans, although unaware of malaria’s etiology, were able to incidentally reduce the risk of its transmission. At the same time, this analysis also indicates that malaria’s entrenchment within Italy, lasting until its elimination in the middle 20th century, may have in part been a consequence of the abatement and breakdown of those very same artifacts and practices which, for a time, curtailed its transmission.

2

ENVIRONMENTAL DETERMINISM AND MOBILITY PRACTICES IN EARLY MEDIEVAL EUROPE: PRELIMINARY NOTES

**Abstract author(s):** Pazienza, Annamaria (Ca’ Foscari University, Venice; University of Nevada, Reno)

**Abstract format:** Oral

The association of the incidence and transmission of disease to particular landscape types or attributes is one of the most essential principles of modern landscape epidemiology; in fact the importance of the environmental as a critical factor in health has been recognized since pre-modern times.

As far back as Classical Antiquity and throughout the middle Ages, indeed, several thinkers established a link between landscapes and human diversity of appearance and way of life on one hand, and disease and/or health risk on the other. Although these early associations were based on assumptions revolving around erroneous philosophical and religious beliefs (e.g. the humoral theory and the climate zonal theory), it is clear that people in the past perceived these associations as having an impact on human behavior.

Indeed, which landscapes and climates they viewed as healthy or prone to disease determined how they used land and its resources, how they moved across space, and which physical and environmental barriers, once crossed, they regarded as risky or good for health, (Metzler, 2009; Ziegler 2016).

This paper intends to look at the reception by early medieval Christian authors, such as Bede, Isidore and Paul the Diacon, of classical medical and environmental knowledge (from Hippocrates to Macrobius) and to investigate to what extent this knowledge affected daily mobility practices specifically related to health promotion and prevention, for instance, as regards the planning of journeys and temporary seasonal residential changes by travelers and other subjects.

3

“PRO MAIORE SANITATE HOMINUM CIVITATIS...ET BORGORUM”. HYGIENE IN THE LATE MEDIEVAL CITIES OF EMILIA ROMAGNA

**Abstract author(s):** Sabbionesi, Lara (Soprintendenza Archeologia, Belle Arti e Paesaggio per la città metropolitana di Bologna e le province di Modena, Reggio Emilia e Ferrara)

**Abstract format:** Oral

In the late Middle Ages the population density in cities increased significantly, and filth became an unavoidable problem. Citizens and legislators had a pragmatic approach to the question: a dirty city was perceived not only as objectively ugly, but also unhealthy and not very functional to the economy. The urban statutes from the thirteenth century are quite explicit in this sense. Of course, the concept of hygiene was evolving and what was deemed acceptable changed over time and space. Regarding the late medieval centuries and the Emilia Romagna region, one of the crucial hygienic concepts was miasma, in other words, corrupted matter or vapours, i.e. excrements, stagnant water, and decaying organic material, which were considered unhealthy and illness causing, and had to be eliminated and removed from the city.

Statutes contain rules for safeguarding urban environment and its hygiene; however, they deal exclusively with public spaces. The result is a total absence of laws that were concerned with the habits and strategies in the private sphere, making those behaviours that characterized domestic environments invisible.

The statutes were quite precise in prohibiting certain public behaviours, such as the abandonment of waste in streets and squares, the presence of latrines on the public road, and the pollution of water supply sources. In addition the statutes also regulated the cleaning of common spaces, and organized services such as waste collection and street cleaning, yet strangely they did not care about how private citizens managed their waste, or about the hygienic conditions inside their homes. Basically, as long as streets, porticos and squares were kept clear, people were essentially left free to privately manage the filth. Therefore only a careful examination of the material sources made available by archaeology helps to understand these aspects in the private sphere.

4

MANAGING MOVEMENT AND PUBLIC HEALTH IN MEDIEVAL BOLOGNA

**Abstract author(s):** Zaneri, Taylor (University of Amsterdam)

**Abstract format:** Oral

Medieval Bologna was a vibrant and dynamic city with hundreds of artisans, craftsmen, students, government officials (and other professionals), as well as animals, all sharing the same streets, neighborhoods, and waterways. As this paper will show, medieval officials were highly concerned with keeping their city and its environs, safe and healthy, during times of stress as well as prosperity, and devoted significant amounts of time and resources to achieve these goals.

Using Bologna as a case study, and by mapping in GIS, historical and published archaeological data relating to urban infrastructure, hygienic regulations, and population demographics, this paper will examine, what were the public health strategies – in other words, how did officials regulate and enact health on a city-wide level, and what were the consequences of these strategies? This research will demonstrate that medieval officials in Bologna employed a spatial logic as they created health regulations and oversaw the construction and maintenance of urban infrastructure. This spatial logic was grounded in an understanding of movement and an awareness of how, where, and when people, animals, goods, water, and waste flowed through the city. To this end, knowledge of space and movement were critical aspects of public health strategies which officials deployed to maintain a healthy and working city.

5

PAVING STREETS TO PURGE MEDIEVAL CITIES FROM FILTH, TRAFFIC CONGESTION AND TO FAVOUR HUMAN MOBILITIES (GHENT, XIVTH-XVTH CENTURIES)

**Abstract author(s):** Hermenault, Léa (Universiteit van Amsterdam)

**Abstract format:** Oral

During the late Middle Ages, as written sources become more prevalent, there are increasing references to street paving in western European cities. Growing studies (Hermenault 2015; Béghin 2017; Coomans 2019; Rager 2020) have recently shown that urban governments tended to invest more and more money in the paving of street during the XIVth and the XVth centuries. This paper aims to explore how urban governments used the paving of streets to facilitate mobility as a cure against the public health woes which resulted of various kind of congestions in their cities.

I will first use medieval prescriptive documentation to show how laying pavement was conceived as a way to avoid the accumulation of filthy mud in the streets (which was considered to be at the origin of disease in the medieval culture) and to ease the cleaning of streets by the flows of rainwater. I will then focus on the case study of Ghent (Belgium) and compare in a Geographical Information

6

## THE USE OF QUARANTINE IN THE INDIAN OCEAN WORLD DURING THE NINETEENTH CENTURY: AN ARCHAEOLOGICAL APPROACH

**Abstract author(s):** Ciancesi, Alessandra (University of Amsterdam; Stanford University)

**Abstract format:** Oral

The practice of quarantine, sadly spotlighted by the global Covid-19 emergency, is arguably one of the most widespread health practices implemented throughout history, or at least from the Middle Ages onwards. The word ‘quarantine’ has often been defined as a place deliberately chosen for the separation and isolation of diseases. This can be applied to all disease vectors, whether goods or animals, or people.

Archaeologists can investigate quarantine sites from different perspectives, such as the use of different quarters and buildings, their diachronic and functional transformation, and their spatial role in landscapes (for example ‘lazarettos’ near towns) and sea-scapes (for example maritime quarantine stations). This paper aims to present a comparative analysis of the spatial organization of some stations, used during the nineteenth century in the European colonies of the Indian Ocean region, with particular reference to French and English overseas territories. During this century, the construction of maritime quarantine stations intensified in conjunction with the escalation of trade, migratory flows, and the consequent outbreak of epidemic diseases. The archaeological investigation of each site has started from the analysis of the distribution of buildings and infrastructure in connection with social segregation between sick/healthy people, males/females, officials/travellers, and Europeans/non-Europeans. In some cases, it has been possible to compare the planned drawings of the station with their realization in the field, which indicates an adjustment to a specific landscape and potential improvements for sanitary purposes.

This study clarifies how much the materialisation of quarantine in the 19th century was influenced by the concepts of disease and disinfection, the persistence of ‘miasmatic theory’, and how social segregation was applied to specific communities and social groups.

## POTENTIALITIES IN USAGE OF HISTORICAL SOURCES FOR ANALYSING HEALTH CRISES IN MAURITIUS THROUGH A LONGUE DURÉE APPROACH

**Abstract author(s):** Deerpaal, Yadhav (Department of History, Iowa State University)

**Abstract format:** Oral

Dr Laurent Musango - the WHO Representative in Mauritius - mentioned in the Mauritius Management and Prevention of COVID-19 Report (October 2020) that the island’s success in tackling COVID-19 also stemmed from its previous experiences in dealing with communicable diseases such as malaria, dengue and chikungunya. There have also been structures and experiences which helped in tracing and treating COVID-19 cases. But how far can history be used to explain responses to contemporary health crises?

While it is not within the scope of the paper to do a comparative analysis through a longue durée approach, it will discuss the potentialities of such a study which could employ archival sources to support archaeological researches. Material and immaterial structures which could have had an impact on the responses to such global pandemics can be discerned over a long stretch of time.

For instance, the report of the 1882 Sanitary Commission which relied extensively on the works of Dr Charles Meldrum discussed the impact of construction processes on water drainage which exacerbated the spread of malaria. Deforestation had a considerable impact and there were even proposals to replant trees. The social inequalities pertaining to the disease were also discussed. The Creoles were much more affected by the disease than the other groups of the population.

Le Cernéen, a major anti-abolitionist newspaper of the French colonists during the nineteenth century British Administration of the island, also revealed how news on health crises circulated alongside the local responses to such diseases. When combined with the detailed colonial reports, such historical sources can be used to support archaeological researches. Analysing them over space and time can help explain not only on the evolution of the material and immaterial structures but also demonstrate the complexities of employing lessons from the past.

## BETWEEN STYLE AND FUNCTION: THE TECHNOLOGY OF NEOLITHIC POTTERY FINISHES IN SE EUROPE

**Theme:** 6. Material culture studies and societies

**Organisers:** Burke, Clare (OREA, Austrian Academy of Sciences) - Amicone, Silvia (Mathematisch-Naturwissenschaftliche Fakultät, Eberhard Karls Universität Tübingen)

**Format:** Regular session

During the Neolithic in SE Europe we see widescale adoption of ceramic production and consumption as ceramics play a larger role in the daily lives of communities. This increasing importance of pottery is paralleled by technological advances displayed through

the use and development of various surface treatments and pigments, which show the remarkable skill and knowledge obtained and shared by Neolithic craftspeople.

Whilst there exists excellent and thorough typological and stylistic research which has provided the foundation for the various chronological and cultural schemes developed in SE Europe, the technological “know-how” behind such developments still lacks systematic and detailed investigation. Importantly, there is a great need to bring typo-stylistic and technological approaches together as it is only through the integration of different methods to the study of pottery that we will be able to build narratives around interaction, innovation, and knowledge exchange. Therefore, the session will bring together a broad range of expertise from archaeology, experimental work and the natural sciences, to present research on various approaches to, and understandings of, slips, pigments and surface treatments across the Neolithic period in SE Europe.

The session aims to develop an interdisciplinary conceptual and methodological approach to the study of Neolithic pottery surface finishes that goes beyond traditional binary narratives of functional vs. decorative. It will also bridge the dichotomy between typo-stylistic and archaeometric approaches to better understand and explain characteristic finishes from a technological and functional point of view, and to examine their role in the wider chaîne opératoire of pottery production and consumption more broadly.

Key themes are the raw materials and technologies used for paints and slips, skeuomorphism and the imitation of other materials (e.g. metal or basketry), and the function and meaning of different pottery styles and treatments including elements such as residue analysis and formal stylistic approaches.

### ABSTRACTS:

1

## AESTHETIC CHOICES? POTTERS’ VALUES IN THE NEOLITHIC OF SOUTH-EASTERN EUROPE

**Abstract author(s):** Spataro, Michela (British Museum)

**Abstract format:** Oral

Early and middle Neolithic ceramics of south-eastern Europe include a wide range of surface finishing, from plain, to polished/burnished, slipped, painted, incised, impressed, and with barbotine application.

This paper will focus on the technology of surface finishes in Starčevo/Starčevo-Criș/Körös pottery from the central and eastern Balkans and Hungary, based on a detailed macroscopic, microscopic, mineralogical and chemical analyses of polished and slipped ware from more than 20 sites (Spataro 2019).

Research over the last twenty years on the absolute chronology of the Starčevo culture (Biagi/Shennan/Spataro 2005; Meadows 2019) supports its typo-chronological subdivision into phases on the basis of pottery shape and decorative patterns, despite the lack of development in pottery fabrics. Some surface treatments changed over time: white pigment was used for the early decorative motifs, barbotine surface treatment began in the second phase, and red and black paint were used for late Starčevo linear and geometric motifs, whereas polishing was applied in all phases. The technology of surface treatments did not vary geographically. The results show a consistent chaîne opératoire, which appeared with the first arrival of the early farmers in the region.

## CAN YOU JUDGE A POT BY ITS COVER? STARČEVO POTTERY FROM THE SITE OF SVINJARIČKA ČUKA, SERBIA

**Abstract author(s):** Burke, Clare (Department of Prehistory and WANA Archaeology, ÖAI)

**Abstract format:** Oral

Early-Middle Neolithic Starčevo pottery assemblages are characterised by a specific range of surface treatments and finishes, with early research often focusing on characteristic designs in relation to defining and understanding both chronological and cultural boundaries. The stylistic coherence between Starčevo assemblages is striking, and work by authors such as Spataro (2019) has demonstrated that this stylistic coherence is also reflected in technological elements related to raw material choices.

This paper will add to current understandings of Starčevo pottery by presenting technological and typological analysis of pottery finishes found at the site of Svinjarička Čuka in southern Serbia as part of the FWF Funded NEOTECH project. The planned programme of interdisciplinary analysis includes macroscopic, petrographic and scanning electron analysis to understand the chaîne opératoire of choices that Starčevo potters were making. The paper will discuss the preliminary results so far which suggest a correlation between technological choices, particular surface finishes and vessel types, including their potential function.

3 BETWEEN STYLE AND PRACTICE: PAINTS AND PAINTING TECHNIQUES IN THE EARLY AND MIDDLE NEOLITHIC OF THE CENTRAL BALKANS

**Abstract author(s):** Bajcev, Olga (Institute of Archaeology, Belgrade)

**Abstract format:** Oral

In the area of the Central Balkans, painted pottery is a recognizable characteristic of the Early and Middle Neolithic (6200-5400 BC), ie the Starčevo culture. What’s more Early Neolithic in this area is sometimes called an „EarlyNeolithic culture of painted pottery“. Archaeological interest in painted pottery dates back to the very beginnings of research and the first works on the relative-chronological systematization of the Early and Middle Neolithic of the central Balkans. However, the archaeologists were mostly focused on typo-stylistic analysis, because ornaments were considered chronologically sensitive, and the “developmental path of ornamentation” from simple rectilinear to complex curvilinear motifs was observed. Painted pottery styles were viewed as something independent that evolved over time. In this paper I want to deconstruct previously defined styles of painted pottery and see them as a combination of different practices: the use of different paints and painting techniques. I will also explore relationships between these practices and ornament structures. The research is based on macroscopic observations of painted pottery from five sites in Serbia: Starčevo-Grad, Grivac, Tečić, Pavlovac-Gumnište, and Pavlovac-Čukar. The results show different variability of paints, techniques, and style between settlements that could indicate a different degree of experimentation or social control between different communities of practice. The new insight into old material challenges some stylistic categories and asks for systematic analysis of paints and pigments to investigate these issues further.

4 SURFACE TREATMENTS AND NEOLITHIC POTTERY: CASE STUDIES IN SERBIA AND MONTENEGRO

**Abstract author(s):** Manem, Sebastien (CNRS, UMR 7055 - Préhistoire et Technologie)

**Abstract format:** Oral

Surface treatments are related to the modification of the superficial layer of ceramics. European Neolithic pottery can reveal a wide variability of surface treatments due to cultural traditions, but also to functional factors since they affect the permeability of ceramics and their resistance to abrasion.

Surface treatments can be classified in two categories: techniques by friction and by coating. Each of these categories involves several techniques. Beyond identifying surface treatment techniques on prehistoric sherds, the question is to understand how this step fits into the chaîne opératoire, a series of operations that transform raw material into finished product as defined by Cresswell.

In this paper, some results from the ERC project EUROFARM will be discussed and based on Neolithic pottery from Montenegro and Serbia illustrating several cultural choices in the Balkans. The focus will be on the observed techniques inventory as well as on the last identified hydric state of the clay paste – leather-hard state or wet state – before the modification of the superficial layer of ceramics in order to understand if the potters continue with the same hydric state or if they modify it during the different stages of the chaîne opératoire from one population or social group to another.

5 STYLE BELOW THE SURFACE: TECHNOLOGICAL VARIATION IN CERAMIC SURFACE TREATMENTS IN NEOLITHIC SE EUROPE AND W ANATOLIA

**Abstract author(s):** de Groot, Beatrijs (The University of Edinburgh)

**Abstract format:** Oral

Decorations and surface treatments on early Neolithic ceramics continue to play a key role in models of the spread of farming to Europe. ‘Waves’ of ceramic styles such as dark-faced-burnished ware and red-monochrome ware have been used as chrono-typological guide-fossils, contributing to still active discussions concerning the location of migration routes an networks. Recent research has looked more closely at the techniques to produce the red slip layer of Early Neolithic monochrome ware in the Balkans, revealing technological variation within the same types of surface treatments (e.g. Spataro 2016, de Groot 2019). Determining the spatio-temporal variation of different techno-styles further can contribute to understanding the processes of imitation, experimentation, learning and interaction that underpin visual similarities in material culture.

This talk provides an initial theorisation of how variation in techniques underpinning ‘similar’ decorations and surface developed during the Neolithic in western Anatolia, the Aegean and the Balkans. By drawing on a number of case-study sites, it will consider the spatio-temporal of techno-styles within dark-faced burnished ware, red-burnished ware, and calcareous encrusted decorations and discuss how future research can complement current views on social interaction, technological change and creativity underpinning the development of similarities in Neolithic ceramic styles.

6 WHITE-ON-RED PAINTED POTTERY IN THE EARLY NEOLITHIC: INTERREGIONAL INTERACTIONS BETWEEN SOUTHEASTERN EUROPE AND WESTERN ANATOLIA

**Abstract author(s):** Alpagut, Canay (University of Tuebingen)

**Abstract format:** Oral

Over the past decades, interaction between Southeastern Europe and surrounding areas has been discussed intensively. It is widely agreed that Neolithic populations spread to Southeastern Europe from Anatolia and the Aegean coastal regions at the turn from the 7th to the 6th millennium calBCE. Among other features, these early farming communities are strongly connected with the first appearance of pottery. Within these emerging networks, pottery production shows great variety from one region to another. The present study therefore focuses in the detection of networks of decoration styles and their connections to specific vessel shapes, with a particular focus to be placed on interregional interactions. Within this context, white-on-red painted pottery (WRPP) plays a central role as it is one of the distinctive characteristics of the Early Neolithic in the Balkans.

The first part of the paper will focus on WRPP in the Aegean. Vessel forms and decoration styles of WRPP from sites like Nea Nikomedeia and Mavropigi-Filotsairi in Western Macedonia, as well as Argissa and Achilleion in Thessaly will be classified. The results will be studied with comparative analysis of the WRPP from sites like Hacilar and Bademağacı in Southwest Anatolia, and Çukuriçi in Central-West Anatolia. In the end, the hypothesis of Anatolian influences in the Balkans through WRPP will be re-evaluated on the basis of statistical analysis.

The second part will concentrate on the area of modern day Bulgaria. Pottery from EN sites like Kovachevo in the Struma River Valley, Karanovo in the Thracian Plain and Dzhulyunitsa-Smardesh in the Lower Danube Basin will be reassessed in order to identify the distribution of the WRPP in different geographic locations. The presented analyses offer a new insight in regional peculiarities and interactive relations of EN pottery in the influential regions of Anatolia, the Balkans and the Aegean.

7 GRAPHITE PAINTED POTTERY FROM THE NEOLITHIC/CHALCOLITHIC BALKANS: AN ARCHAEOMETRIC AND EXPERIMENTAL APPROACH

**Abstract author(s):** Amicone, Silvia (Competence Center Archaeometry-Baden Wuerttemberg, University of Tübingen; Institute of Archaeology, University College London) - Solard, Baptiste (Competence Center Archaeometry-Baden Wuerttemberg, University of Tübingen; Institute for Natural Scientific Archaeology, University of Tübingen) - Tsirtsoni, Zoi (CNRS-UMR 7041 Archéologies et Sciences de l’Antiquité. Maison d’Archéologie et d’Ethnologie R. Ginouvès) - Malamidou, Dimitra (Ephorate of Antiquities of Serres) - Grebska, Malgorzata - Todorova, Nadezhda (Regional Museum of History, Blagoevgrad) - Berthold, Christoph (Competence Center Archaeometry-Baden Wuerttemberg, University of Tübingen)

**Abstract format:** Oral

Graphite decoration on ceramic vessels is a distinctive phenomenon spread over most of the Balkans during the 5th millennium BC and became a dominant trait for Neolithic and Chalcolithic material cultures in the region for over 1000 years.

Given the vast spatial and chronological distribution of graphite decoration, the technological knowledge connected to this technique must have travelled via channels of interaction that resonate on a wide temporal and geographical scale. Therefore, the study of such a phenomenon is of enormous importance to the understanding of mechanisms governing the diffusion of ideas that catalyse the formation of shared material cultures. At the same time, as a rare naturally occurring substance the use of graphite by potters across such a wide region could indicate that they participated in or benefitted from specialist networks that would be very important to trace.

However, mostly due to the lack of systematic technological investigations that include not only a wider range of sites, but also employ a variety of modern analytical methods, the emergence and development of this decorative technique for pottery remains unclear to this day. An interdisciplinary approach employing macro-observations and analytical methods including thin section petrography, XRPD, micro-XRD, micro-Raman and SEM analysis was applied to a selection of experimental and archaeological specimens. The experimental ceramic samples were produced both under controlled conditions in the laboratory and in the field within an actualistic framework. The archaeological samples come from different areas of the Balkans with a focus on the Struma Valley and cover the full chronological development of this technique. The results enabled us to trace the craft network and technological tradition behind this decorative phenomenon giving important information about the procurement and processing of raw materials as well as essential insights into the pyrotechnology related to graphite painted pottery.

8 WHERE ‘POTTERY STYLES’ INTERTWINE: DECORATIVE APPROACHES AND SURFACE TREATMENTS ALONG THE NEOLITHIC STRUMA RIVER (BULGARIA)

**Abstract author(s):** Kulow, Malgorzata (Regional Museum of History-Blagoevgrad) - Dzhhanfezova, Tanya (University of Oxford)

**Abstract format:** Oral

The hidden technical decision-making behind specific ‘decorative styles’ can usually be uncovered. However, the meaning of style or tradition is not necessarily always clear. Interpreting stylistic variations and surface finishes may thus be excitingly challenging in areas (or even at individual sites), where ‘pottery styles’ intertwine. This refers to a spectrum of phenomena where traditions meet and boundaries blend; where new styles emerge or old ones gradually transform, leading to ever greater complexity, and so forth.

9 We tackle the topic by analysing Early Neolithic painted pottery in hand specimens, thin sections and by using scanning electron microscopy. Within the extended region of the Struma River valley (southwestern Bulgaria), we focus on those cases where several Neolithic ‘decorative styles’ are present within specific micro-regions or even at one and the same settlement.

We highlight the variable surface treatment approaches, as well as the different raw materials, pigments and colorants used in pottery production. Examined are various types of clays, organic and inorganic substances that are major constituents when shaping the surface finish procedures. Interpreting these within multi-layered context helps widen the research horizons and reach well beyond the traditional techno-typological approaches, especially in regions where various ‘styles’ intertwine.

9 TECHNOLOGY OF POTTERY FINISHES IN NEOLITHIC GREECE

**Abstract author(s):** Bonga, Lily (unaffiliated)

**Abstract format:** Oral

The ceramic assemblage of Neolithic Greece is characterized by wide range of surface treatments and technologies, some with narrow chronological duration and limited geographic range. Importantly, the technological trajectory of pottery finishes is not a linear development. Pigments were used before and after firing on burnished or unburnished vessels. Both mineral and organic pigments were used, sometimes on the same vessel. Burnishing was often used as a surface finish in its own right as a highly polished surface, or, depending at which stage the vessel was burnished, as “pattern-burnished” motifs created by the selective differential burnishing of leather-dry vessels or as “ripple-burnished” patterns and motifs made on damper vessel bodies. Different firing techniques were also used to create desired surfaces, such as the combination of smudging and iron reduction firings to produce “black-topped” pottery.

This paper presents a diachronic overview of the types and technology of pottery finishes in Neolithic Greece, focusing on the types of pigments (e.g., ferruginous, bitumen), at which stage they applied to the vessel (e.g., pre- or post- firing), if, when, and how the vessel was burnished, and the firing conditions used. Since the existence of the same raw materials and technologies were available to potters throughout the Neolithic period, it seems that cultural and social pressures dictated the choices the potters employed. Both clear innovations and influence from external interactions can be detected. The mechanisms by which technical knowledge of pottery production was developed and transmitted will be revisited in order to help to bridge the typo-stylistic and archaeometric dichotomy of traditional ceramic analysis.

10 DEFINING THE BOUNDARIES OF CLAY SURFACES: SURFACE TREATMENTS AND MATERIAL EXPRESSIONS OF THE POTTERY FROM NEOLITHIC DISPILO, MACEDONIA, GREECE

**Abstract author(s):** Voulgari, Evangelia (School of History and Archaeology, Aristotle University of Thessaloniki) - Sofronidou, Marina (Ephorate of Antiquities of Drama) - Kotsakis, Kostas (Professor Emeritus of Prehistoric Archaeology, School of History and Archaeology, Aristotle University of Thessaloniki)

**Abstract format:** Oral

The Neolithic Dispilio in Lake Kastoria is the first wetland settlement excavated in Greece and has been systematically investigated since the 1990s’ by the Aristotle University of Thessaloniki. In parallel to morphology and technology, pottery study has been focused on restoring as many vessels as possible. The result is a large corpus of whole pots and profiles, an amount unique in the neolithic ceramic assemblage of Northern Greece, which opens new possibilities in understanding pottery’s role in the social practices of the neolithic communities. In the last two years, Aristotle University’s participation in the ERC-funded EXPLO Project has supported the study’s continuation.

In this paper, we examine typology, size, surface treatments, decoration techniques of pots during the development of the habitation from the mid-6th to the early 5th millennium BCE. By selecting material covering this long period, it is possible to define variations in the vessels’ morphological, stylistic and functional parameters through time and assess pottery production and consumption in the neolithic settlement’s successive phases.

A distinct category in the ceramic assemblage is a group of zoomorphic, anthropomorphic and boat-shaped pots. Their short presence may suggest that neolithic pottery expanded at some point its domain, constructing new meanings and relationships. Based on spatial distribution, we can assume that the neolithic inhabitants used them in various practices and locations but never in “unusual” or “special” contexts. Although their role probably might have been of some symbolic significance, they were still containers with use wear similar to those of other clay vessels, decorated or not.

11 THE SKEUOMORPHISM OF THE CERAMIC CONTAINERS’ DECORATION IN THE CHALCOLITHIC

**Abstract author(s):** Gheorghiu, Dragos (National University of Art; ITM Macao)

**Abstract format:** Oral

Viewed from an ethnoarchaeological perspective, the significance attached to the decorative elements of some prehistoric pottery may have had an apotropaic and prestige conferring role, and therefore, should be investigated as representing a material surface with value. From this perspective it is important to consider the role of some ceramic decoration as skeuomorphic, just as the shape of some ceramic containers suggests the imitation of containers made in other materials.

This paper will present analysis of the skeuomorphic elements within the decoration of Vădastra and Cucuteni ceramic containers, two geographically separate Chalcolithic traditions which possess different decorative styles but whose techniques for decorating ceramics (incision and painting), provide insights into both the materiality of copied objects and of the materials positioned around containers. Additionally, data gained from experiments performed with different materials to reproduce the decorative patterns identified has provided more detailed insights and hypotheses about the functionality of these decorated containers, whilst the analysis of the decorative patterns within these ceramic groups has revealed common elements, supporting a similar axiological concept for decorative patterns relating to skeuomorphs, despite differences in technique and style.

12 PAINTING AND PIGMENTS IN THE CHALCOLITHIC OF EASTERN ROMANIA. CASE STUDY: CUCUTENI CULTURE POTTERY

**Abstract author(s):** Drob, Ana (“Alexandru Ioan Cuza” University, Interdisciplinary Research Institute, Science Department, Arheoinvest Research Center, Iași.) - Bolohan, Neculai (“Alexandru Ioan Cuza” University, Faculty of History, Iași) - Vasilache, Viorica (“Alexandru Ioan Cuza” University, Interdisciplinary Research Institute, Science Department, Arheoinvest Research Center, Iași)

**Abstract format:** Oral

This interdisciplinary study uses a range of analytical methods to examine Chalcolithic Cucuteni Culture pottery and pigments. The methods employed include macroscopic (form, color, wall thickness, firing and inclusions types, distribution, form and sorting), optical microscopy (texture of the paste, surfaces and inclusion details), SEM-EDX (elemental composition), and  $\mu$ FT-IR (chemical compounds).

The analyzed pottery fragments come from several newly discovered settlements in eastern Romania and were analysed to investigate different raw material and technological elements. Analysis of ceramic paste has provided information about the raw materials and production technology, inclusions, finishes, firing temperature and functionality of the vessels, complimented by analysis of the red, black, and white pigments used in the painting of Cucuteni Culture pottery. The results will provide data about their nature, the preparation methods used, and the source of the raw materials.

Although there are a number of studies that have focused on the pigments of the Cucuteni Culture, they remain in a small number comparable to the large area it covered. Through this study we want to contribute to the expansion of current data and understandings, with new technological information about painted ceramics from eastern Romania.

13 ARCHAOMETRICAL INVESTIGATION OF THE WHITE COLOUR INLAID ON EARLY ENEOLITHIC POTTERY FROM SOUTHERN ROMANIA

**Abstract author(s):** Opris, Vasile (Bucharest Municipality Museum) - Simion, Corina - Mirea, Dragos (Horia Hulubei National Institute for Physics and Nuclear Engineering) - Bartha, Cristina - Rostas, Arpad - Sava, Florinel - Secu, Mihail - Vlaicu, Mihai (National Institute of Materials Physics) - Matei, Elena (National Institute of Materials Physics) - Dimache, Madalina (Gumelnita Civilisation Museum)

**Abstract format:** Oral

The aim of our paper is to present preliminary results obtained by complementary archaeometric methods applied on 39 samples of white pigments inlaid on Boian tradition pottery, Vidra phase (c. 4900-4700 cal BC). The pottery came from three Early Eneolithic settlements from southern Romania (Sultana, Vidra and Vlădiceasca respectively). The samples submitted to the study were selected by taking into account that they belonged to decorated vessels produced in three approximately contemporary sites, located close to each other in the south of the Romanian Plain. Archaeometric investigations consisted of the application of XRF, in air-PIXE and EDX methods for chemical composition determination, XRD and FT-IR for mineralogical determinations, RES for the characterization of paramagnetic centers, DSC for thermal transformation analysis and SEM for microstructure observation. The questions we asked and for which we come up with answers were: (1) what is the nature of the compounds in the composition of the pigments? (2) how to identify the samples from the point of view of the chemical and mineralogical composition? (3) what pigment preparation technologies and recipes were used? (4) what are the possible sources of raw materials? (5) what regional traditions and local particularities can be identified? (6) how do the new results fit into the general picture of the white pigments inlaid on Early Eneolithic pottery produced in the Lower Danube area?

352 EMPOWERING THE VOICELESS. THE ROLE OF THE RURAL POPULATION IN STATE BUILDING AND CHRISTIANISATION IN EAST-CENTRAL EUROPE

**Theme:** 6. Material culture studies and societies

**Organisers:** Vargha, Maria (University of Vienna; Charles University, Prague) - Stefan, Ivo (Charles University, Prague) - Rácz, Tibor (Ferenczy Museum Center)

**Format:** Regular session

The proposed session aims to bring together researchers from Europe, who are dealing with different, and yet connected affairs of the archaeological heritage of the networks of state and church, and especially, religious changes in the Middle Ages. In the last decade, interest in the research of Christianisation has been growing. Diverse approaches in history were observable; still, researchers have investigated the process primarily focusing on the higher levels of the ecclesiastic network, mostly due to the availability of

ABSTRACTS:

1 SACRIECE – THE EXAMPLE OF HUNGARY

**Abstract author(s):** Vargha, Maria (Charles University, Prague)

**Abstract format:** Oral

This introductory abstract showcases SACRIECE (State And ChRistianisation in East-Central Europe), a research project at Charles University, Prague, funded by the PRIMUS grant scheme. The project focuses on Christianisation from the point of view of the archaeological heritage of the rural population. Christianisation in the examined region was a crucial agenda of state formation; however, the impact of the largest segment of the society, the rural population is seldom examined. The project aims to create a digital database of those archaeological features connected to this process; early churches, cemeteries, rural and ecclesiastical power centres. The digital, geospatial database allows the data to be contextualised, analysed, and compared at a regional level, processing data that has never been investigated at such scale. By applying new methods on neglected sources and creating an extensive, regional, comprehensive digital database, the project aims to provide new narratives about East-Central Europe's Christianisation, and in this case, the results of the analysis will be shown by the example of Hungary.

2 CHRISTIANIZATION OF RURAL COMMUNITIES AS A NEGOTIATION PROCESS: THE CASE OF THE CZECH LANDS, 10TH - 13TH CENTURIES

**Abstract author(s):** Stefan, Ivo (Department of Archaeology, Charles University Prague)

**Abstract format:** Oral

Everywhere across early medieval Europe, written sources focus primarily on the Christianization of the highest elites. The long lasting process of Christianization of rural communities is usually seen as a passive top-down enforcement of Christian norms. However, it should rather be seen as a complex mutual negotiation between the demands of the church and (although) conservative, yet changing local communities. Furthermore, the countryside was not socially homogeneous. Some local kin groups were involved in elite networks and could act as agents of the new cultural code. The paper tries to formulate basic questions, possibilities and limits of the archaeological study on the adaptation of Christianity in the Central European countryside and is mainly based on the Czech lands case study. We can detect the influence of the primary power/church centres on their surroundings and the gradual founding of local churches, which later merged into the parish network. The responses of the rural communities reflect on changes of funeral customs. The comparisons between respective regions of Central Europe enable to reveal the common trends and differences.

3 QUALITATIVE DATA – NEGLECTED DATA OR ANOTHER PIECE IN THE MOSAIC?

**Abstract author(s):** Janovský, Martin (Czech University of Life Sciences; Charles University)

**Abstract format:** Oral

There is a common assumption that only higher levels of the ecclesiastical network carry information about the process of Christianisation. The possible approaches to the processing of qualitative data in the context of lower ecclesiastical network during Early Medieval Ages will be discussed further on.

The project translates archaeological sites connected to this process as point data, which allows to interpret and assign values to them that were not explored before; their place in the landscape and their context in it. The initial analysis of these points concerned the nature of their arrangement – where and why can clusters appear? How do they relate to different natural, sociopolitical, or other features? This approach allows to categorize the data using clustering and hierarchical methods. More sophisticated analyses could be created using additional attributes. Another option was to use multiple correspondence analysis to define similar groups and find a relationship between variables. Furthermore, diverse forms of site-catchment analysis can help understand how the local churches worked as a network, and what factors have influenced its formation.

A vital aim of the project is to create an extensive database covering the territory of the Czech Republic, part of Poland and Hungary, and the publishing of the result of our analysis in the form of an interactive web-based map. This presentation will show the database model we have created that allows the investigation of various qualitative data and examines the options for presenting the data including OpenAtlas, GitHub or R and JavaScript libraries DT (data tables) and leaflet (interactive maps).

4 THE EMERGING PROCESS OF THE LATE MEDIEVAL PARISH NETWORK

**Abstract author(s):** F. Romhányi, Beatrix (Károli Gáspár University of the Reformed Church)

**Abstract format:** Oral

Rural churches appeared in the medieval Kingdom of Hungary parallel to the church organisation, from the eleventh century on. However, the real parish network did not emerge before the end of the thirteenth century, although its earliest examples appeared as early as in the mid-twelfth century. The first written evidence documenting the fully established system is the papal tithe register compiled between 1332 and 1337 that has been analysed recently from a quantitative, statistical point of view. Based on that analysis and on its comparison to similar European documents, mainly from England and France, the paper aims to clarify the demographic and economic background of the organisation of the parish system. The results will be compared with the results of archeological and architectural research of the late Árpadian (parish) churches, as well as with recent results on the impact of the Mongol Invasion (1241-1242) for to better understand the long-term process.

5 CHRISTIANIZATION OF MEDIEVAL BOHEMIA IN THE PERSPECTIVE OF ARCHEOLOGY

**Abstract author(s):** Cechura, Martin (The Museum of West Bohemia, Pilsen, Czech Republic)

**Abstract format:** Oral

The beginnings of Central European states and their Christianization belong to the progressive themes of European archeology. New archaeological research as well as a new interpretation of older finds bring new perspectives on these complicated processes. The paper will pay attention to the relationship between early and high medieval cemeteries and their connection with the emergence of the church network. Taking into account written sources, hypotheses about the circumstances and the course of their foundations are considered. Older and current historical concepts are newly evaluated.

Compared to the supposed discontinuity between older row burial sites and church cemeteries, it appears that in many cases there was a direct spatial connection. The churches were founded in places of older settlement, as well as in places of older cemeteries. Archaeological research has documented wooden buildings and stone architecture too. In several cases, spatial and functional links to residences have been explored. In many cases, a greater age of churches was proved. Some churches were preceded by an older sacral building. The position of some churches on important roads and borders indicates their symbolic role. The results of archaeological research formulated to questions who were the builders of these churches and what was their role in medieval society. Thus, the view of the early Christianization of the early medieval population and the individual conversion of the elites are fundamentally changing.

6 THE GREAT MORAVIAN HILLFORT BOJNÁ-VALY AND ITS SURROUNDING

**Abstract author(s):** Robak, Zbigniew (Slovak Academy of Sciences)

**Abstract format:** Oral

The author aims to present most recent findings concerning the Bojná-Valy hillfort—located in today's Western Slovakia—changing the cognitions of its function and chronology. The conclusions have been drawn based on the newest findings of archaeological research and the investigation of relations between the centre and its vicinity—nearby settlements, early feudal manor houses, cemeteries and Nitra as one of the main centres of Great Moravia.

Previously, both scientific and popular literature presented the Bojná-Valy hillfort as a seat of the Slavic elite and one of political, cultural and economic centres of Great Moravia. However, recent findings do not corroborate the view. Specifically, despite the intense archaeological research, we were unable to identify traces of a burial ground or sacral facilities in the hillfort or in its close vicinity. There are no traces of elite seats either. Instead, the archaeological research suggests that the hillfort served as a primarily military object.

Interestingly, in the area of the hillfort, there are two sacral facilities (rotundas) that could be dated back to the same period as the hillfort. The rotundas are related to archaeological sites known as the earliest feudal manor houses in the area. Furthermore, in the area with open settlements, there are burial grounds contemporary to the hillfort with graves of warriors. Why, then, there was no manor house, church or chapel and traces of any burials at the hillfort? It seems that the absence of such features corroborates the view that the Bojná-Valy hillfort was not a political centre but merely a military camp. Furthermore, contrary to laymen beliefs, recent research supports the hypothesis that the hillfort should not be dated back to the times of Pribina (beginning of the 9th century) but rather to the times of Svatopluk instead (turn of the 9th and 10th century).

7

LIFE AND DEATH ON THE RIVERBANKS: ‘DEVIANT’ BURIAL PRACTICES FROM MEDIEVAL RURAL CEMETERIES IN THE IRON GATES REGION

**Abstract author(s):** Parvanov, Petar (Department of Medieval Studies, Central European University)

**Abstract format:** Oral

From the early 12th century onwards one of the most contested frontier zones in medieval East-Central Europe was the Danubian region of Braničevo and the Iron Gates. The strategically critical area witnessed a prolonged political and military efforts by multiple states to seize and maintain control. Even more, the interregional confrontation involved Catholic (the Kingdom of Hungary) and traditionally Orthodox (Byzantium, Bulgaria, and Serbia) powers. The shifting political allegiance of the principal centres in the region was the most permanent factor in the high-level processes well until the Ottoman conquest.

Conspicuously, contemporary rural cemeteries show a significant concentration of grave disturbances and unusual treatment of the deceased (a.k.a. deviant burials). They are often perceived as long-lasting pagan reminiscences in popular Christianity practiced against harmful spirits and revenants. However, recent approaches also link them to periods of social unrest and transformation.

The current presentation will use examples on both sides of the Danube from sites like Trnjane, Ilidia, Vajuga-Pesak etc. The available evidence gives an opportunity to examine long-term processes and individual agency within marginalized social groups in the past. Arguably, power structures existing in local communities were reinforced through funerary display and supplement, sometimes even replace the direct influence of distant power centres.

8

KNIGHTS HOSPITALLER AND CONSOLIDATION OF CHRISTIANITY: INDICATIONS OF RELIGIOUS CHANGES AND SOCIO-POLITICAL PROCESSES IN THE ARCHAEOLOGICAL RECORD

**Abstract author(s):** Belaj, Juraj (Institute of Archaeology) - Sirovica, Filomena (Archaeological Museum in Zagreb) - Karbić, Marija (Croatian Institute of History)

**Abstract format:** Oral

Archaeological excavation at Stari grad (Castle) site in Ivanec, a small town in north-western Croatia, yielded evidence of cemetery continuously used from the end of 11th to the 17th century. The cemetery was initially formed around the Romanesque church which was later replaced with an adjacent Gothic church, built by the Knights Hospitaller. A total of 326 graves were excavated at the site and divided into five chronological phases, distinguished by clear changes in the burial practice. Analysis of both the recorded elements of each phase and documented differences apparent through the centuries implies not only changes in religious practices of local communities but also deeper socio-political transformations in the area. This is especially evident in the graves of the second phase which are and marked by the appearance of certain, previously not recorded characteristics. Approximately dated to the 13th century, they sometimes contain animal teeth and knives, i.e. artefacts usually considered as elements of certain pre-Christian funerary practices. Sometime during the same period, the area fell under the administrative authority of the Knights Hospitaller who in the 14th century, built the new Gothic church of Saint John the Baptist. Around the church, a new cemetery formed attributed to the third phase and characterized by a complete lack of small finds and other earlier elements. Consideration of the documented phenomena shows that although it is not always possible to delineate meanings of certain reoccurring characteristics, combined analysis of archaeological and historical data can enlighten the relationship between material remains, religious practices and socio-political processes.

354

THE PLANT STORY. CULTIVATION AND USE OF PLANTS IN THE NEOLITHIC AND EARLY BRONZE AGE IN THE CENTRAL AND EASTERN EUROPE

**Theme:** 7. From global to local: Baltic-Pontic studies

**Organisers:** Sobkowiak-Tabaka, Iwona (Faculty of Archaeology, Adam Mickiewicz University, Poznań) - Rennwanz, Joanna (Institute of Archaeology and Ethnology, Polish Academy of Sciences, Poznań) - Kočár, Petr (Institute of Archaeology Academy of Sciences of the Czech Republic, Praha) - Vostrovská, Ivana (Department of History, Faculty of Arts, Palacký University, Olomouc)

**Format:** Regular session

Since the dawn of history, plants have accompanied humans in providing them food, fuel for fires, building materials and clothing. However, it was only in the Neolith that the domestication of plants had begun. The sedentary way of life was related to plant cultivation and livestock breeding, and, as a result, people started to live in larger groups and constructed permanent settlements. Domestication as well as the subsequent spread of plant cultivation had revolutionized the course of prehistory.

The session aims to explore the importance of plants of the Neolithic and Early Bronze Age populations. We would like to discuss the problem of the potential regional variety of cultivation, ways of harvesting and plant foods storage, as well as processing plants to prepare food. The debate on the plant-based diet will be of particular interest to us, especially in relation to the recently intensified isotope research. Furthermore, the use of wild plants is also a significant issue for medicinal purposes, diversification of diet and for technical purposes. We, too, would like to discuss the use of plants for the production of pottery and clay objects as well as for the construction of residential houses and economic buildings. Moreover, we also aim to consider the traces of plants on flint and stone tools.

An application of sampling strategy as well as flotation on local archaeological sites are also noteworthy issues that we would like to go over. We intend to show the impact of a method on the results of analysis on specific examples and evaluate the value and validity of analytics of the archival materials. Technique applied to a dry archaeological context is rare, however, numerous finds of water wells, throughout the Europe, yielded an unusual insight into the Prehistoric economy and environment.

1

USE AND PROCESSING OF PLANTS IN EARLY NEOLITHIC CENTRAL EUROPE. WELLS – A SPECTACULAR ARCHIVE OF THE PAST HUMAN-PLANT INTERACTIONS

**Abstract author(s):** Vostrovská, Ivana (Palacký University Olomouc) - Kočár, Petr (Czech Academy of Sciences)

**Abstract format:** Oral

Water wells and their sedimentary fill represent one of the richest Prehistoric archives of various sets of environmental and cultural proxy data. In our study, we offer an insight into Early Neolithic plant husbandry as reflected by analyses of water-logged plant macro- and micro-remains from otherwise dry sites in Czechia.

Prehistoric wells are rarely found archaeological structures. To date, just a little over 100 wells have been documented at 53 Early Neolithic European sites. Recently excavated three wells from Czechia – Uničov in Moravia, Velim in central, and Ostrov in eastern Bohemia – were systematically sampled for plant remains. Despite relatively small sediment volumes studied, each well yielded tens of thousands of plant macro-remains of over 100 taxa.

By an in-depth quantitative and qualitative analyses and correlation of pollen and macro remains data we in this paper present new information on ways of plant cultivation and gathering and their processing for food, medicine, fibres, and textiles. We also bring notes on the character of Early Neolithic east-central European landscapes and the ways humans shaped them.

2

THE IMPORTANCE OF EDIBLE AND TENDED WILD PLANTS IN THE PREHISTORIC SUBSISTENCE OF ROMANIA

**Abstract author(s):** Brasoveanu, Casandra (Arheoinvest Research Centre, Science Department, Institute of Interdisciplinary Research, Alexandru Ioan Cuza University of Iasi) - Danu, Mihaela (Faculty of Biology, Alexandru Ioan Cuza University of Iasi) - Bodi, George (Institute of Archaeology, Romanian Academy - Iași Branch)

**Abstract format:** Oral

For thousands of years, humans all over the world have depended on edible wild-growing plants, but the usage of these resources implied special cultural knowledge, in order to harvest, prepare, cook or perform any other form of processing. Thus, when identified within an archaeological context, wild taxa help improve the existing knowledge regarding the plants that might have been used in alimentation or other purposes (e.g.: medicinal uses) by specific groups of people, but also can provide important considerations regarding the social component of the communities studied. The archaeobotanical studies conducted on the findings belonging to Romania’s prehistorical sites have consisted, mostly, of carpological determinations. Lately, technological and methodological advances have allowed the identification of many more cultivated and wild plants through the study of pollen grains. Archaeobotanical results, as well as archaeological data, allow us to corroborate the possibility of culinary and / or medicinal uses by the prehistoric communities. For this research, we synthesised and interpreted the carpological and palynological data obtained from the research of prehistorical sites of Romania, along with the results of the analysis of natural sedimentary sequences from different Quaternary stations. Wild plants, such as Cornus mas, Sambucus nigra, Vicia sativa, Rumex crispus, Rumex acetosella, Geum urbanum, Lithospermum officinale, Polygonum aviculare, Galium spurium, Thlaspi arvense, Phragmites australis, Viburnum lantana etc., have been identified in Romania’s archaeological contexts dating back to the Neolithic and Bronze Age. Thus, the analyses of archaeobotanical remains allow us to better understand the floral diversity, in terms of wild species that would have been present in the prehistoric territory of Romania, and also the connection between groups of people and the environment inhabited.

3

HEALING OR MAGIC? TRACES OF PLANT USE BY THE FUNNEL BEAKER CULTURE COMMUNITIES IN POLAND

**Abstract author(s):** Rennwanz, Joanna (Institute of Archaeology and Ethnology of the Polish Academy of Sciences) - Sobkowiak-Tabaka, Iwona (Faculty of Archaeology, Adam Mickiewicz University, Poznań)

**Abstract format:** Oral

From prehistoric times, healing treatments have played an important role in the life of ancient communities. However, they are also an extremely hard-to-grasp element of the archeological context. Traces of healing treatments are most often visible on the bones or teeth of the discovered skeletons (surgical interventions), but it is especially difficult to find evidence of the use of plants. Manifestations of the medicinal use of plants are a subject of intense scientific discussions and sometimes are even denied (i.e. Shanidar Cave from northern Iraq).

This paper will present the finds from the settlement of the Funnel Beaker Culture in southern Poland, as they were a reason for taking up the topic of using plants for healing and magic purposes in the Neolithic period in Poland. The equipment that had survived in the feature indicates a highly specialized activity (profession) of its user, and some finds confirm the knowledge of the properties

4

PLANT MACROREMAINS AND THE EARTHEN LONG BARROWS: WHAT FOLLOWS FROM THE ARCHAEOBOTANICAL EVIDENCE FROM NEOLITHIC SITES IN MUSZKOWICE (SOUTH-WESTERN POLAND)

**Abstract author(s):** Przybyl, Agnieszka (Institute of Archaeology, University of Wrocław) - Kofel, Dominika (Institute of Archaeology and Ethnology, Polish Academy of Sciences)

**Abstract format:** Oral

Archaeological excavation, conducted at two Neolithic monumental burial sites with several earthen long barrows of the Funnel Beaker culture in Muszkowice (the Polish Sudeten Foreland) in 2018-2019, provided us a significant number of soil samples that were used in the archaeobotanical study. In the presentation we are going to outline some results of recent analysis of plant macroremains retrieved by flotation from the soil samples that were collected from the barrow No. 3 at Muszkowice site 18 and barrow No. 1 at Muszkowice site 45.

As the researchers of the first burial mound recognized at Muszkowice site 18 in the early 2000s reported, former attempts to obtain palynological data from the barrow did not bring positive results. Unfavorable soil conditions resulted in almost complete decomposition of organic matter and the lack of preserved pollen. This time, after another sampling in the field, the archaeobotanical study of charred plant macroremains was conducted. Thus several species have been identified, belonging to both, cultivated and wild plants taxa. After the taxonomical identification some of the plant macrofossils have been subjected to radiocarbon dating.

The data undeniably confirmed cereal agriculture. But as a result, some further questions arose, e.g. about the function of the plants identified here, in the Funnel Beaker culture burial context: whether the charred plant macroremains were related to the funeral rituals and activities, and consequently, they could be associated with the time of the burial mounds construction, or whether they predate it and reflect the past of the place where the earthen long barrows were erected. We will briefly discuss these questions in the presentation.

The studies presented were conducted with the financial support of the National Science Centre, research project No. 2017/25/B/HS3/01442.

5

ENOUGH IS AS GOOD AS A FEAST – SAMPLING STRATEGY AND A REPRESENTATIVENESS OF ARCHAEOBOTANICAL ASSEMBLAGES

**Abstract author(s):** Kapcia, Magda - Moskal-del Hoyo, Magdalena - Korczyńska, Marta (W. Szafer Institute of Botany, Polish Academy of Sciences, Kraków)

**Abstract format:** Oral

Sampling in archaeobotanical research is a crucial factor, which has an impact on the knowledge about plant usage in prehistory. This is especially important for the so-called dry archaeological sites, in which only a small part of plants used by prehistoric people are preserved mainly due to environmental conditions. From that type of archaeological sites, mainly charred plant materials can be gathered for studying the great variety of uses of plants by ancient societies and learning the history of local flora. In order to show the importance of sampling strategy for palaeoethnographic and palaeoenvironmental studies we will present data from loess-mantled areas of southern Poland coming from recently excavated Neolithic archaeological sites (i.e. the Linear Pottery culture site of Biskupice 18; the Lengyel-Polgar culture of Spytkowice 26; the Funnel Beaker culture site of Mozgawa 1-3) and Middle Bronze Age sites (i.e. the Trzciniec culture site of Lipnik 5). Different strategies of sampling were tested at these sites starting from sampling of selected layers only, through collecting samples randomly distributed in pits, until normalized sampling in the standardized grid, analysed with geostatistic tools permitting to obtain spatial information of the data. The results will be discussed in the context of the type of archaeological features and their possible function. In addition, plant macro-remains obtained from these sites will be compared with other contemporary archaeobotanical assemblages known from the regions to discuss the optimal sampling strategies applied to different types of archaeological features.

6

OLD DATA - NEW INTERPRETATIONS. SUBSISTENCE STRATEGIES OF FUNNEL BEAKER CULTURE POPULATION

**Abstract author(s):** Sobkowiak-Tabaka, Iwona (Faculty of Archaeology, Adam Mickiewicz University, Poznań) - Rennwanz, Joanna (Institute of Archaeology and Ethnology, Polish Academy of Sciences, Poznań) - Diachenko, Aleksandr (Institute of Archaeology of the National Academy of Sciences of Ukraine)

**Abstract format:** Oral

This paper presents the reassessment of the empirical evidence on the proportion of different crops, which were grown by the Funnel Beaker Culture (TRB) populations at the territory of modern Poland. The critical analysis will focus on the methods of sampling and the evaluation of their influence on the obtained results. Additionally, analyzes of archival materials, their reanalysis and the current methodological approach in archaeobotany will be taken into account. Moreover, we will present the evidence of some regional

differences in the TRB crop structure. We will also discuss whether this is the result of the local natural and cultural conditions of the TRB community or the adopted strategy of sampling and data analysis at the archaeological site. As on the one hand, there is a noticeable repeatability of the ratio of cultivated plants, on the other hand, some differences in this respect are observed locally.

The obtained results make possible new conclusions on their diet, subsistence strategies, and catchment areas, and also raise new questions on the economy of the Neolithic populations of Central Europe. The proposed methodology may be further used for the analysis of agricultural activities of different archaeological populations.

COMMUNITY ARCHAEOLOGY AND CLIMATE THREAT RESPONSE

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** McGovern, Thomas (CUNY Graduate Center and Hunter College) - Dawson, Thomas (School of History U St Andrews Scotland)

**Format:** Discussion session

Climate changes pose a worldwide threat to the archaeological record and the heritage of local and global communities. Experience gained by climate change response initiatives thus far have underlined the key role of community-based archaeology in mobilizing and providing effective response to the dire challenges we now face. In multiple world areas, from Caribbean to Greenland, archaeologists (many indigenous) and local communities have formed partnerships to assess, prioritize, record, and rescue rapidly disappearing science and heritage. The growing realization that archaeological deposits represent a "distributed observing network of the past" of great value to modern resource managers and sustainability planners is increasingly tied to the recognition of deep local expertise in resource management and sustainable commons management. Partnerships across communities of knowledge are being enhanced and accelerated by innovative applications of new technology and techniques, and formal inclusion of professional digital media producers to create new tools for recording and wider communication of results are now becoming widespread. We are learning new ways of co-producing knowledge while mobilizing in the face of climate threats. This session will bring together projects and practitioners from multiple teams and communities and will work to share ideas and best practice approaches while connecting broadly across world regions. This session is sponsored by the Integrated History and Future of Humans on Earth (IHOF) program and draws upon expertise from SAA and EAA climate impact communities.

ABSTRACTS:

1

CLIMATE CHANGE THREATS TO HERITAGE IN ALASKA-WORKING ON AN ORGANIZED RESPONSE

**Abstract author(s):** Jensen, Anne (University of Alaska Fairbanks)

**Abstract format:** Oral

Alaskan archaeological sites, especially those in permafrost areas and those along the coast or rivers, are being threatened by climate change. There have been a number of projects which have dealt with specific sites which are threatened with damage or obliteration, but there is no wider organized response. This leaves many sites at risk. While community members are often very concerned, often they are dealing with threats to current community infrastructure, like houses and water plants, which must take priority.

Attempts are beginning to organize some type of trained rapid response capability, to at least be able to document what is exposed accurately and rapidly, and to gather samples and document diagnostic artifacts, before the next storm or flood removes them altogether. Due in part to the size and nature of Alaska, this has proven to be somewhat of a challenge. This paper will describe the current state of this quest.

2

CANCARE: THE CANADIAN COASTAL ARCHAEOLOGY RESCUE EFFORT

**Abstract author(s):** Betts, Matthew (Canadian Museum of History)

**Abstract format:** Oral

The destruction of archaeological sites due to sea level rise and climate instability has been characterized as a global heritage crisis. With the longest coastline and freshwater ecosystem in the world, Canada sits at the apex of a looming catastrophe. While Canada was initially a global leader in rescue-archaeology, the decentralization of heritage legislation changed the way archaeological sites were protected and mitigated. These changes led to the development of a robust cultural resource management (CRM) industry that protects sites from development. Unfortunately, no such robust system was developed to protect sites from destruction by natural causes. As the pace of sea-level rise has increased with global warming and climate instability has increased storm-linked erosion, the destruction of archaeological sites has reached a critical point. In collaboration with Indigenous experts, provincial and territorial archaeologists, academics, and knowledge holders, the Canadian Museum of History has been attempting to build a new infrastructure to address this issue with a program that is national in scope, but community-based in practice.

3

PROTECTING THE PERIPHERIES - COLLABORATIVE ARCHAEOLOGY, STEWARDSHIP, AND PRESERVATION AT TWO ‘FRONTIER’ SITES

**Abstract author(s):** Victor, Megan (Queens College, CUNY)

**Abstract format:** Oral

Community-based and collaborative archaeology stand as key strategies in staunching the deleterious effects of climate change on archaeological sites. Partnerships formed between local communities, scholars, and – at times – government agencies can lead to substantive responses to climatic threats in the form of documentation and preservation. This is most crucial in locations distanced from the steady gaze of passersby, for the threats to these locales became equally secluded, often leaving the sites’ vulnerability unnoticed. This paper discusses two projects in the United States where such peripheral places were protected, thanks to the diligent efforts of community-driven, collaborative archaeology. The excavations at former fishing village of Smuttynose Island at the Isles of Shoals – off of the Maine /New Hampshire Border in New England – took place through the Shoals Marine Laboratory in partnership with the community-based Smuttynose Island Stewardship Program. The excavations explored climate change at the Isles of Shoals, with an eye to current conditions, while also seeking to record and protect the site before the sea could strip it from the island’s shore. At Highland City, Montana, high in the Rocky Mountains, the Highland City Project worked with the local descendant community and the Forest Service to record the boundaries of the site threatened by ice and fire. Changing winter conditions and prolonged forest fire seasons have both posed considerable challenges to the continued preservation of the once-thriving gold town. Both projects found ways to record, excavate, and – where possible – preserve these archaeological locations with input from the communities whose heritage are most tied to them. The excavations at Smuttynose Island and Highland City represent two ways of approaching climatic threats to remote archaeological sites.

4

CULTURE, HERITAGE AND IDENTITIES: IMPACTS OF CLIMATE CHANGE IN NORTH WEST EUROPE (CHICC)

**Abstract author(s):** Kerr, Sarah (Aarhus University)

**Abstract format:** Oral

Anthropogenic climate change is threatening the heritage of North West (NW) Europe, particularly through increased incidence of storm activity impacting the coasts of Ireland, Scotland and Denmark. Heritage loss or damage has an impact on the lives of local communities. It may impact their livelihoods, their sense of place and belonging, and their perception of climate change; therefore, heritage loss impacts their cultural identities. This paper will introduce and discuss CHICC, an MSCA-funded project which explores the impact of climate change-driven heritage loss on communities’ cultural identities.

CHICC involves the comparative compiling of long-lens narratives of three damaged or partially lost heritage sites in Denmark, Ireland and Scotland. In this paper, I will provide an overview of the methodology; in particular, the co-creation of an open-access, on-line resource in the form of a deepmap. Deepmapping allows the creation of environmental and cultural histories with temporally and spatially mapped content showing site development, climate change impact, and contemporary response. Crucially, CHICC’s deepmap utilises a Citizen Science approach which allows for the co-production of knowledge free of disciplinary boundaries and top-down steering. The aim of this is to create a deepmap which is, at once, a research tool through which cultural identity can be examined; and an output allowing a digital experience of a site no longer physically accessible. The paper will summarise the shifts in cultural identities, as a result of climate change-driven heritage loss, detectable through this methodology.

5

DONOP: MAKING SPACES FOR INDIGENOUS VOICES IN CLIMATE CHANGE RESEARCH

**Abstract author(s):** Newsom, Bonnie - Kelley, Alice (University of Maine)

**Abstract format:** Oral

Understanding the intersection between human behavior, the environment, and climate change in the past enhances our capacity to address contemporary climate change issues. Archaeological sites are important data sources which inform such understanding and provide insight into the human/animal/environment dynamic over time. The Distributed Long-term Observing Networks of the Past (DONOP) was conceived as a way to elevate the value of archaeological sites as data sources for global change research (Hambrecht et al 2018). While archaeological sites can provide invaluable information for understanding changing climate, it is important not to reduce archaeological sites to mere data sources. In North America, most sites falling within the scope of this network represent Indigenous heritage spaces that carry socio-cultural meaning for contemporary Indigenous groups. As such, Indigenous stakeholders should have a role in determining how archaeological data sets are collected, used, and managed. This paper discusses efforts underway in Maine to elevate Indigenous voices in archaeological practice, specifically as it pertains to coastal shell heap studies and climate change impacts. Here we showcase two case studies centered on the role of Indigenous stakeholders in shell heap management and research in Maine, one working in a field school setting and the other involving a citizen science effort.

6

THE ALLUITSOQ PROJECT: A COMMUNITY-BASED ARCHAEOLOGICAL RESEARCH PROGRAM AT A THREATENED MISSION STATION IN SOUTH GREENLAND

**Abstract author(s):** Turley, Cameron (The Graduate Center, City University of New York) - Bendtsen, Aká (Ilisimatusarfik) - Coleman, Wendi (The Graduate Center, City University of New York)

**Abstract format:** Oral

Archaeological heritage at the former Moravian mission of Lichtenau in South Greenland (established in 1774) is presently threatened by rising sea levels, coastal erosion, and rising ground temperatures. Project directors Turley (City University of New York) and Bendtsen (Ilisimatusarfik) launched the Alluitsoq Project in 2019 with goals to simultaneously rescue imminently endangered archaeological deposits and to develop productive, long-term partnerships with Alluitsoq’s descendant community for capacity building and knowledge co-production. Three working seasons which have included excavations, ethnographic fieldwork, school lectures, and numerous site visitors have produced large collections, early progress on valuable datasets, and growing community partnerships. While we provide a summary of fieldwork and analysis results which remain in-progress, our primary focus in this paper is the project’s foundational community-based practice. From the perspectives of both Kalaallit and foreign researchers we reflect on the privilege and responsibility of working with and for this community, some failures, successes, and lessons learned, and where our community partners’ knowledge and needs are driving interpretation, leading to new research questions, and expanded designs for mutual participation. This work takes place within a still broader context. As a members and collaborators with the North Atlantic Biocultural Organisation, Integrated History and Future of Humans on Earth, and Bifrost Environmental Humanities, the Alluitsoq Project is one element of a transnational effort to build productive community-based praxes for capacity building and knowledge co-production.

7

BOSTON HARBOR ISLANDS ARCHAEOLOGY AND CLIMATE IMPACT PROJECT

**Abstract author(s):** West, Catherine (Boston University) - Bagley, Joseph (Boston City Archaeology Program) - Albert, Marc (National Park Service)

**Abstract format:** Oral

The Boston Harbor Islands Archaeology and Climate Impact Project represents a collaborative effort among groups from around the Commonwealth of Massachusetts to examine and mitigate threats to archaeological sites in the Boston Harbor Islands. The project is headed by the City Archaeologist of Boston in partnership with the Massachusett at Ponkapoag tribe, the National Park Service, Boston University, and other partners. The Boston Harbor Islands Archaeological District is listed on the National Register and represents the most intact and complete archaeological record of the region’s history, with continual intensive use for thousands of years to the present. Most of the archaeological sites are located along the shore, where many are threatened by active erosion. Despite the importance of the archaeological district and their vulnerable coastal location, many of the sites have never been documented and there has never been a system of monitoring in place. This project will document archaeological sites at risk of loss due to climate change and other threats on the Boston Harbor Islands: first, we will create the framework for determining site location and risk through a collaborative approach that combines data from known archaeological sites, potential archaeological sites, Indigenous perspectives, and existing climate and harbor science. Second, we will apply the framework to an island in Boston Harbor for an island-wide Sensitivity, Risk, and Management Plan (SRMP). Finally, we will begin risk mitigation by creating a community science shoreline monitoring program to actively track erosion at archaeological sites and conduct archaeological surveys to document the most at-risk sites before they are lost.

8

PRESERVATION THROUGH TRANSLATION? CO-PRODUCING A MODERN ECO-HOME BY INTEGRATING INTANGIBLE ARCHITECTURAL HERITAGE

**Abstract author(s):** Romankiewicz, Tanja (University of Edinburgh, School of History, Classics and Archaeology)

**Abstract format:** Oral

My architectural analysis of later prehistoric houses along the North Sea littoral has identified a dynamic concept of domestic architecture, where permanency is created through place not through structure, where houses adapt and transform to changing needs, and where homes metamorphose into byres, byres into gardens, and gardens into homes. This reflects a cyclical concept of architecture, both sustainable and sustaining. It reflects a definition of architecture beyond walls and roofs that encompasses a holistic understanding of how a house sustains a household.

Such architectures, however, create only ephemeral archaeological evidence, and are by their nature already hard to preserve; so, how can we preserve the theoretical concept behind them? Their sustainability relies on re-usable, compostable, renewable materials, which if applied today could reduce the carbon footprint of modern housing. Metamorphosing houses can also adapt to modern dynamic lives and changing family situations, much easier than a concrete box. But how can we translate such ancient, intangible, architectural concepts into modern ones, beyond imitation or pastiche, or ending up having to live under Bronze Age conditions? Are such concepts best preserved via wide but broad dissemination and education, or by individual, practical engagement that has a deep reach instead. Can we preserve these concepts not by communicating something old, but by translating it into something new? How much do we gain and lose in this way, and where do the challenges lie? And how can such deep impact be multiplied and expand its reach?

I propose to discuss this idea of preserving intangible heritage through modern translation by introducing a case study from the Netherlands, where we (an archaeologist, a traditional builder/archaeologist and a local resident) started designing a cyclically metamorphosing “home-place”, inspired by ancient architectural concepts but translated into a new, modern setting, with all its chances and challenges.

9 COASTLINES, COMMUNITIES AND CLIMATE CHANGE

**Abstract author(s):** Dawson, Tom (University of St Andrews)

**Abstract format:** Oral

Natural processes threaten thousands of heritage sites around the globe. One area where destruction can be seen happening before our eyes is at the coast. Much of the damage is caused by slow and steady erosion, but storms and hurricanes occasionally destroy entire sites overnight. Either way, the result is the same, the irreversible loss of vital heritage information. With no developer to pay for expensive survey or excavation, new ways of working need to be found.

The key is partnership working, with important roles for heritage agencies, researchers and local community members. For the past twenty years, archaeologists in Scotland have been working with local communities, testing new ways of recording heritage sites threatened by natural processes. Coastal surveys have been followed by practical projects, where locally-valued sites have been prioritised for action. In addition to excavation, other types of action have been selected by the local groups, ensuring that something is saved of sites before they are destroyed.

Much has been learned over the years and this presentation will highlight the positive benefits of partnership working.

359 FOOD CULTURES IN ANCIENT SOCIETIES

**Theme:** 6. Material culture studies and societies

**Organisers:** Kubiak-Martens, Lucy (Biax Consult, Zaandam) - Kirleis, Wiebke (Kiel University)

**Format:** Regular session

Food is a fundamental link that connects people across cultures and generations. Research into food cultures has long since become a key topic of ever increasing importance in social archaeology and cultural anthropology, supported by innovative natural scientific approaches on nutritional values and metabolism. Food production, processing, distribution and consumption are the pre-conditions for the existence of human life. They shape subsistence on different spatial, temporal and social scales with culinary traditions being one important expression of human livelihood that reflects social identities and social practices.

This session addresses the economic and social relevance of food and food procurement in ancient societies. It aims at exploring the links between the diversity of food choices and changes therein with trends and tendencies in agrarian production and advances in agrarian technology. The session will also focus on past dietary habits in the light of the interaction between humans and food, behavioural variability, social inequality and identity.

We invite contributions that consider different bioarchaeological and food analysis methods, likely combined with studies on the specific expressions of the material culture related to food procurement and food processing, molecular and SEM analyses, micro-wear and microfossil analyses of archaeological artefacts used in food preparation (flint and stone tools), ethnographic studies and experimental archaeological approaches. As food cultures often vary regionally, contributions from all geographic regions and all archaeological periods are welcome. This session is intended to bring together specialists who are using various highly sensitive methods in our search for a better understanding of different food cultures and culinary traditions hidden in the archaeological record.

ABSTRACTS:

1 UNRAVELLING HUNTER-GATHERER FOOD TRADITIONS IN NORTH-EAST EUROPE: RESULTS FROM THE INDUCE PROJECT

**Abstract author(s):** González Carretero, Lara (The British Museum; Museum of London Archaeology - MOLA) - Courel, Blandine (The British Museum) - Lucquin, Alexandre - Bondetti, Manon - Robson, Harry - Craig, Oliver (University of York) - Heron, Carl (The British Museum)

**Abstract format:** Oral

Food traditions involving food processing, preparation, cooking and ultimately consumption have generally been hidden to the eye of the archaeologist. Traditional archaeobotanical and zooarchaeological analysis, although being greatly successful at identifying the procurement and presence of plant and animal ingredients, have often lacked the means of providing insights into culinary habits and cuisine. This paper presents results from the INDUCE (The Innovation, Dispersal and Use of Ceramics in NW Eurasia) project funded by the European Research Council (ERC), with a focus on the combined approach of biomolecular (isotopes, GC-MS) and microscopic analysis (Digital Microscopy and SEM) of absorbed residues and charred food residues or ‘foodcrusts’ preserved in pottery vessels from Mesolithic communities in North-East Europe. This paper shows the latest finds from selected sites in the

study area in addition to presenting some of the latest methodological advances in the identification of plant and animal ingredients as well as potential food recipes.

2 FOOD PRODUCTION, LANDSCAPE-USE AND THE DIVINE AT THE BRONZE AGE HILLFORT HÜNENBURG NEAR WATENSTEDT, LKR. HELMSTEDT (1200-650 BC)

**Abstract author(s):** Uhlig, Tobias - Heske, Immo (Georg-August-Universität Göttingen) - Grefen-Peters, Silke (Braunschweig)

**Abstract format:** Oral

The Hünenburg near Watenstedt, Lkr. Helmstedt lies in the hilly plains north of the Harz Mountains in Northern Germany. The hillfort with its contemporary extramural settlement dates to the late bronze and early Iron Age. Its location on the western spur of the Heeseberg offers a prominent position controlling the fertile loess-covered plains. Archaeological Investigations between 1998 and 2018 have shown it to be a hub of power, specialist metalwork and exchange with a population density that surpasses the traditional models of single farmsteads by far. Research on the matter of food production, distribution and the utilisation of the surrounding cultural landscape has been conducted on an interdisciplinary scale. A distinct farming strategy is visible that relies on summer- and winter grains. The excellent bone preservation allows a detailed view on Bronze Age animal husbandry. The results obtained from these sources by S. Grefen-Peters, Braunschweig, can be placed in their archaeological context within the settlement. Cattle stands out as the foremost species kept for meat production, followed by ovicaprids and a surprisingly small proportion of pigs. The bone material yielded a vast spectrum of cut and chop marks as well as traces of cooking and roasting, revealing different patterns of food preparation. Meat supply seems to have been managed centrally with hints towards a spatial arrangement of production and procession. The difference between roasted and cooked meats seems very important in its social dimensions. Several depositions of articulated animal bone groups inside the settlement show differing or no dislocation patterns at all, hinting at a different intent. Completely breaking with manipulation and distribution patterns established for the settlement these might be regarded as manifestations of ritual activities and ceremonial meals hinting at a more complex entanglement of Human-Animal-Relations.

3 DELICACIES FOR THE KAMI: SACRED FOODS IN JAPANESE PROTOHISTORY

**Abstract author(s):** Fernández, Irene Minerva (Independent researcher)

**Abstract format:** Oral

Food is an essential issue within cultural research. Way of life, religion, taboos, and beliefs are reflected in the different dietary habits, together with some aspects of the physical environment and relationships with other food-exchanging groups of the human communities.

Within the regular consumption foodstuff, a reduced group of foods are part, not only of the daily diet, but as well of the sacred realm. These foods began to be consumed in ritual contexts for different reasons: their physical/chemical traits, their socio-economic production implications, their association with different mythological passages or religious beliefs, or the physical effect that its consumption produces in the organism. Sometimes, these foods also reach the status of “foodstuff worthy of being consumed by the gods”, either in the form of an offering, either through the act of commensality.

This work’s aim is to analyze the characteristics of ritual use foodstuff during Japanese Protohistory, specifically during Yayoi (1000/900 BC- 250/300 CE) and Kofun (250/300 - 710 CE) eras, although it will be essential to carry out an exhaustive review of consumption habits of such foods during other different periods, with the purpose of elucidating whether the ritual consumption of the studied food has a long tradition in the Japanese archipelago and, that being the case, determining the context of the origin of the ritual consumption.

4 AN INTEGRATED PERSPECTIVE ON FOOD IN THE BRONZE AND IRON AGE IN THE NETHERLANDS

**Abstract author(s):** van Dijk, Joyce (Archeoplan Eco) - Theunissen, Liesbeth (Cultural Heritage Agency)

**Abstract format:** Oral

Food is the basis of our existence but surprisingly little has been written about this topic for the Bronze and Iron Age. Although excavations in the past yielded much data about arable farming, animal husbandry and trade in food products, very little is known about the storage of food products, the preparing and cooking of food or the way in which the meals were enjoyed. In 2019 a group of enthusiastic specialists and archaeologists teamed up to bring together data about food supply, food processing and the preparing of food in the Bronze and Iron Age. This interdisciplinary approach made it possible to create an up-to-date overview of the menu of farmer societies in the first two millennia BC. It is clear these people used all available possibilities to combine the cultivation of crops, the keeping of livestock and their natural environment. The general assumption that the Bronze and Iron Age societies lived with their backs to nature and that gathering, hunting and fishing no longer played a role in the food supply is refuted. In-depth discussions between the specialists and archaeologists not only led to a new differentiated picture of the available nutrients but also to surprising matters, such as everyday meals versus festive dinners, and a lack of ‘cutlery’ in settlement contexts. As a result of the integrated approach new thoughts on food are put forward which lead to promising research directions in the future.

5 **CULINARY TRADITIONS BEYOND INGREDIENTS: IDENTIFYING CERAMIC VESSELS USED IN COOKING PRACTICES OF THE SOUTH-CENTRAL ANDES**

**Abstract author(s):** Scaro, Agustina - Musaubach, María (Institute of Andean Ecorregions - CONICET-UNJu)

**Abstract format:** Oral

Culinary knowledge, traditional dishes, preparation forms and equipment, and commensality practices, within Andean cosmovision, involve a way of understanding the world. They are transmitted from generation to generation, thus constituting the culinary heritage. The study of culinary knowledge and practices, its loss or adaptation provide information about the social, economic and productive life of the communities. Even more, it addresses changes and continuities in communities' lifestyle, as reflected in their food. In the last fifteen years, Quebrada de Humahuaca (North of Argentina) has been the scenario where culinary heritage was re-discovered. Recipes and ingredients found in different Andean environments were highlighted and revalued from traditional to tourist and "haute cuisine" contexts. However, old-style equipment, especially ceramic pots and wooden utensils, have been replaced almost entirely by metal and plastic ones. This paper aims to infer about possible uses given to archaeological ceramic vessels in traditional Andean culinary preparations. We did the survey based on published local cookbooks, ethnographic records of roasted corn/beans and chicha. Morpho-functional and use-alteration study of archaeological vessels were also carried out. The latter were recovered in the south-central sector of Quebrada de Humahuaca. From this multidisciplinary approach, we seek to advance in the understanding of past culinary practices and the role that vessels played in various contexts of food preparation and commensality. Likewise, to revalue traditional knowledge and practices related to the South-Central Andes Culinary Heritage.

6 **PLANT PROCESSING IN TIGRAY DURING PRE-AKSUMITE AND AKSUMITE PERIODS (>800 BCE-700 CE): PRELIMINARY RESULTS OF STARCH ANALYSIS FROM GRINDING STONES**

**Abstract author(s):** Ruiz-Giralt, Abel (CaSEs – Complexity and Socioecological Dynamics Research Group. Departament de Humanitats, Universitat Pompeu Fabra) - Nixon-Darcus, Laurie - D'Andrea, Catherine (Department of Archaeology, Simon Fraser University) - Biagetti, Stefano (CaSEs – Complexity and Socioecological Dynamics Research Group. Departament de Humanitats, Universitat Pompeu Fabra; School of Geography, Archaeology and Environmental Studies - GAES, University of the Witwatersrand) - Madella, Marco (CaSEs – Complexity and Socioecological Dynamics Research Group. Departament de Humanitats, Universitat Pompeu Fabra; School of Geography, Archaeology and Environmental Studies - GAES, University of the Witwatersrand; ICREA) - Lancelotti, Carla (CaSEs – Complexity and Socioecological Dynamics Research Group. Departament de Humanitats, Universitat Pompeu Fabra; ICREA)

**Abstract format:** Oral

In this paper, we explore plant processing activities during Pre-Aksumite (>800-50 BCE) and Aksumite periods (50 BCE-700 CE) in NE Ethiopia. We analysed plant microremains from grinding stones recovered at two archaeological sites: the Pre-Aksumite rural site of Mezber (ca. 1600 BCE-1 CE) and Ona Adi (ca. 600 BCE-700 CE), an urban center occupied continuously from the Late Pre-Aksumite period to the fall of the Aksumite kingdom. Both sites are located in the historic province of Tigray and, together, they cover the whole chronology of Pre-Aksumite and Aksumite cultural horizons - two of the most notable socio-political entities of recent African prehistory.

Both sites are being investigated in the framework of the Eastern Tigray Archaeological Project (ETAP). Archaeobotanical, zooarchaeological and isotopic evidence at Mezber document a fully developed agropastoral economy, with an early presence of Near Eastern imported wheat, barley, lentils, flax and livestock such as cattle, sheep, goat and donkey. At Ona Adi, ETAP began extensive excavations in 2014 and in-depth analyses of ceramics and lithics, as well as animal and plant remains, and radiocarbon dating are currently ongoing. Here, we present the first results of the starch analysis from grinding stones recovered throughout the complete chronocultural sequence of both sites. 58 samples from 33 grinding stones were studied, recording a total of 2010 grains of starch. Multiple starch morphologies were identified at both sites, including C3 and C4 cereals, as well as legumes and tubers, though more specific taxonomic identification is still ongoing. Overall, these preliminary results point to the use of a wider range of plant products than what has been identified in previous carpological studies. They also seem to attest for the presence of small-seeded C4 species in earlier chronologies than previously recorded. Further analysis (e.g. phytoliths) are ongoing in order to confirm these hypothesis.

7 **DIETARY PRACTICES IN ITALY: A DIACHRONIC RECONSTRUCTION FROM THE NEOLITHIC TO THE BRONZE AGE**

**Abstract author(s):** Cortese, Francesca (Prehistoric Archaeology Laboratory. University of Rome Tor Vergata) - Achino, Katia (Prehistoric Archaeology Laboratory. University of Rome Tor Vergata; Quantitative Archaeology Lab, Department of Prehistory, Autonomous University of Barcelona; Institute of Archaeology ZRC SAZU) - De Angelis, Flavio (Centre of Molecular Anthropology for Ancient DNA Studies, University of Rome Tor Vergata) - Gatta, Maurizio (Prehistoric Archaeology Laboratory. University of Rome Tor Vergata, Italy; University of York, Department of Archaeology) - Scorrano, Gabriele (Lundbeck Foundation GeoGenetics Centre, GLOBE Institute, University of Copenhagen; Centre of Molecular Anthropology for Ancient DNA Studies, University of Rome Tor Vergata) - Silvestri, Letizia (Prehistoric Archaeology Laboratory. University of Rome Tor Vergata; Durham University, Department of Archaeology; Sovrintendenza Capitolina ai Beni Culturali) - Rickards, Olga (Centre of Molecular Anthropology for Ancient DNA Studies, University of Rome Tor Vergata) - Rolfo, Mario (Prehistoric Archaeology Laboratory. University of Rome Tor Vergata)

**Abstract format:** Oral

Food procurement has always been a critical human concern. Diachronic studies regarding dietary practices and a synergetic approach between Archaeology and Biology permit to understand the transforming subsistence strategies of human communities. In this context, Carbon and Nitrogen stable isotope analysis are useful to reconstruct reliable food and subsistence habits of ancient populations.

This work aims at analysing Italian archaeological bioremaines to provide a diachronic human diet reconstruction from the Neolithic to the Bronze Age, exploring the importance of food in the social structures. The first part of the research involves an interpretative exploration of Italian dietary habits during the Prehistory by analysing stable isotope data from published works. The second part of the work focuses on Mora Cavorso Cave, located in Central Italy and characterised by a human frequentation from the Neolithic to the Bronze Age. The cave presents a burial deposit of at least 28 individuals dated to the Neolithic period, a single Copper Age burial, and a large Bronze Age faunal assemblage. The stable isotope analyses carried out on the human and faunal bones points out similarities and differences in the subsistence strategies between the people that attended the cave in different times. Mora Cavorso data will be compared with those available in literature to achieve a more reliable reconstruction of food relevance in Italian contexts.

Diachronic comparisons show that Italy was a striking crossroads of dietary shifts and technological innovations. The Neolithic is a crucial moment due to the transition from an acquisitive to a productive economy. The data obtained from Mora Cavorso Cave allowed us to place this site in the Italian scenario, highlighting the diversity of food choices, trends, and technological advances in farming activities developed throughout Italian Later Prehistory.

8 **RECOGNIZING FOOD PRACTICES IN THE LATE NEOLITHIC VINČA SETTLEMENTS: THE QUESTION OF SCALE AND SPACE**

**Abstract author(s):** Obradovic, Djurdja - Dimitrijevic, Ivana (Institute of Archaeology, Belgrade)

**Abstract format:** Oral

In this study, we combine compositional and contextual evidence to recognize different food related activities inside the Late Neolithic (Vinča culture) settlements. We will focus upon storage and preparation of plant- and animal-based food, as well as disposal of food refuse. The study is based on the data from the Late Neolithic settlements in the region of Central Pomoravlje (Serbia), primarily from the sites of Drenovac and Pavlovac-Gumnište. Both sites have large faunal and botanical assemblages; the Late Neolithic settlements were inhabited for several centuries (5300-4600 cal BC), relatively large (15h and 40h), and enclosed by the ditches. At the site of Drenovac, a significant portion of the central part of the settlement was excavated, including more than 10 houses. Investigation of houses and their immediate surroundings enabled the comparison of inside and outside space use; furthermore, it gave an insight into possible rites after the house collapse and abandonment. Excavations at Pavlovac – Gumnište site revealed the large portion of the peripheral part of the settlement with numerous pits, open-air hearths, ovens and ditches, which gave us a unique opportunity to study the use of outside space for cooking activities and refuse disposal.

By considering both archaeobotanical and archaeozoological data we were able to obtain a comprehensive insight on diet and different ways of food processing, as well as to consider different scales of food practices, i.e. the ones resulting from activities of a smaller (i.e. household) or a larger group of people. Detailed spatial analysis of food practices indicated variations in space use and activities between the central and peripheral parts of the settlements.

9 **NEOLITHIC DIET AS HIDDEN IN HUMAN COPROLITES FROM THE SWIFTERBANT SITES IN THE NETHERLANDS**

**Abstract author(s):** Kubiak-Martens, Lucy (BIAX Consult, Biological Archaeology & Environmental Reconstruction)

**Abstract format:** Oral

Commissioned by the Cultural Heritage Agency of the Netherlands (RCE), BIAx Consult Biological Archaeology & Landscape Reconstruction is leading the project 'Neolithic human diet' based on studies of human coprolites from Swifterbant sites in the Netherlands excavated before 2007. A group of specialists from BIAx Consult, Delft University of Technology (NL), Newcastle University (UK), Universitat Autònoma de Barcelona (Spain), and ArchaeoBone (NL) are working together, incorporating their research methods.

The coprolites are in fact the missing links in our knowledge of the prehistoric diet, as they offer evidence for dietary diversity, preparation of food, and consumption. The study of coprolites gives a unique opportunity to reconstruct the most complete spectrum of foods that were consumed, both cooked meals and (plant) foods that were eaten raw. This contribution focuses on human faecal remains from two sites of primary interest in this project, S3 and S4. Both sites are located on small natural levees in the creek landscape of the Swifterbant area. They are dated to the classic phase of the Swifterbant culture (c. 4300- 4000 cal. BC). At both sites, many human faecal remains were found in the refuse layers. The approached methodology is based on the integration of traditional and scanning electron microscopy. The main research questions of this project are concerned with the dietary diversity of the Swifterbant culinary tradition, with attention to both plant and animal components. The evidence for the consumption of plant foods in general, and cereals in particular, are of great interest. The questions about the crucial shift, the introduction of cereals to the Swifterbant diet, and the actual role of cereals versus wild plant foods are to be more accurately answered.

A CASE STUDY ON PLANT FOOD STORAGE AND SURPLUS MANAGEMENT OF THE FIRST AGRICULTURAL SOCIETIES OF SE EUROPE

**Abstract author(s):** Marinova, Elena (Landesamt für Denkmalpflege am Regierungspräsidium Stuttgart, Laboratory for Arc) - Takorova, Dessislava (National Institute and Museum of Archaeology, Bulgarian Academy of Sciences) - Demeulenaere, Eline (KU Leuven) - Nikolov, Vassil (National Institute and Museum of Archaeology, Bulgarian Academy of Sciences)

**Abstract format:** Oral

Storage practices are a vital element of the subsistence strategies of the early agricultural societies as such facilities are securing food resources on a long term and precondition for sustainable demographic growth. Recent excavations at the Early Neolithic (6100- 5850 cal BC) settlement horizons of Slatina, one of the largest settlements situated on one of the Neolithization route between the Aegean littoral and the Danube Basin, revealed abundant storage structures in several buildings. In the current paper we present the archaeobotanical finds from over 70 storages in their detailed archaeological context majority (ca. 50) preserved at least partly in situ. In the most of the intact storage vessels the staple crops are found as pure concentration of one species and very few have mixed character. Some of the plant concentrations were found not associated with clay vessels, most probably stored in perishable containers. The majority of the uncovered storages of cereals were found in unrushed state (together with the chaff), but few of them contained clearly processed (grinded or broken) cereals, showing also intermediate stages of food preparation which took place in the household. Apart of annual crops (mostly hulled wheats, lentil and pea) also ca. 6 concentrations of gathered from the wild plants (like Cornelian cherry, plum and apple/pear) were found and they confirm clearly the importance of the wild plant resources in the Early Neolithic economy of the site. Due to the good preservation, it was possible to estimate the approximate (preserved) volumes of the stored plants and estimate relative importance of each group in the different buildings, and therefore to give detailed quantitative information on the past plant husbandry of an Early Neolithic site and to explore its diversity of storage facilities and plant food resources.

STABLE ISOTOPIC AND MOLECULAR ANALYSES OF SURFACE AND ABSORBED RESIDUES FROM A YEAR-LONG EXPERIMENT REVEAL MULTIPLE TIMESCALES OF COOKING HISTORY

**Abstract author(s):** Swift, Jillian (Bishop Museum) - Miller, Melanie (University of Otago; University of California, Berkeley) - Whelton, Helen (University of Bristol) - Hammann, Simon (Friedrich-Alexander University Erlangen-Nürnberg) - Cramp, Lucy - Evershed, Richard (University of Bristol) - Hastorf, Christine (University of California, Berkeley)

**Abstract format:** Oral

Chemical analyses of organic residues recovered from archaeological pottery can provide insights into ancient culinary practices and resource use. However the processes of residue formation, including the timescales captured by the chemistry of surface and absorbed pottery residues, has been understudied. Our team designed a year-long cooking experiment where we cooked 7 recipes that included mixtures of C3 (wheat and deer meat) and C4 (maize) foods in unglazed pottery, and at the end of the experiment we changed recipes for a few final cooking events. We utilized stable isotope analysis and lipid residue analyses to study the chemical composition of the resulting residues and their relationship to our known ingredients over the experimental period. Over the course of the experiment, three different residue forms could be distinguished in the vessels: two surface residue forms (larger charred macro-remains and a thin-layer organic patina) as well as the absorbed residue within the pottery fabric itself. Their chemistry reflected different timelines of cooking events from the pot’s use history. The larger, superficial charred macro-remains had bulk stable carbon and nitrogen stable isotope values which reflected the final foods cooked in the vessel. Thin-layer patina residues accumulated over time and were found to contain chemical markers of previous cooking events but were skewed to the chemistry of the final foods prepared in the pot. Finally, the absorbed lipid residues were slower to change and primarily reflected foods cooked earlier in the experiment, with little chemical evidence of the final ingredients that were cooked. These findings suggest that careful comparison of multiple types of archaeological pottery residues can provide more detailed insights into the full course of a vessel’s life history.

FOOD CULTURES IN COLONIAL SETTINGS

**Abstract author(s):** Orendi, Andrea (ArchaeoConnect GmbH, Department of Archaeological Sciences, Archaeobotany Laboratory) - Tal, Oren (Department of Archaeology and Ancient Near Eastern Cultures, Tel Aviv University) - Lichtenberger, Achim (Institut für Klassische Archäologie und Christliche Archäologie/Archäologisches Museum, University of Münster)

**Abstract format:** Oral

Food cultures underwent many developments and changes through time. One aspect within the topic of food cultures in ancient times might be the migration of food and dietary habits through migrating people. One migration process is the colonization of a foreign territory by new settlers, as their cultural identities, such as food, reach the new colonized regions.

Two case studies from the southern Levant will be discussed via food cultures in colonial settings. Tel Iztabba (2nd cent. BCE) located in the Jordan valley was founded by the Seleucids after their occupation of Palestine. The settlement was part of Nysa-Scythopolis (Beth She’an), a major administrative centre in Hellenistic Palestine. The other case study, Arsuf/Arsur is located on the coast of the southern Sharon plain. The Fatimid (9th-11th cent. CE) settlement was conquered by the Crusaders in the early 12th century CE. Due to its occupational history this site offers the opportunity to compare two successive food cultures (the Islamic and the Crusader/Christian) with different dietary laws and habits.

Based on the archaeobotanical data from both sites the paper will discuss possible variations of food cultures at sites with a colonial background. Therefore, various questions arise, such as whether the colonial settlers relied on local plant resources, whether new crops were introduced to the local agrarian resources, and whether variances in the food cultures can be identified in the archaeobotanical records at all.

SOCIAL ARCHAEOLOGY OF FOOD IN EARLY MEDIEVAL RURAL IBERIA (5TH-9TH C. CE)

**Abstract author(s):** García-Collado, Maite (University of the Basque Country - UPV/EHU; University of York)

**Abstract format:** Oral

This paper draws a social history of food in early medieval rural Iberia based on the comparison of dietary patterns in three Iberian regions (Madrid-Toledo, Basque Country, Catalonia) between 5th and 9th c. as revealed by carbon and nitrogen stable isotope ratios on bone collagen. Ten rural populations were subjected to osteoarchaeological analysis for age and sex estimation and palaeodietary reconstruction. They included fifteen human assemblages and eight fauna datasets for a total of 280 human and 115 fauna samples. The isotopic characterisation of domestic herbivores was not only useful for the definition of local isotopic baselines of each ecosystem, but also for investigating agrarian practices. It was revealed that livestock management strategies shared many common features within the same region and the data obtained pointed at the existence of complex agrarian systems. Humans also presented some regional affinity in their dietary patterns, but there were greater differences between populations from the same region and within them. All individuals had terrestrial diets largely based on C3 resources with variable contributions of C4 plants and animal proteins. Age and sex did not stand out as decisive factors in the configuration of diets and only the youngest individuals showed distinct dietary patterns due to breastfeeding. Social status as expressed through grave goods was associated with  $\delta^{13}C$  values and crop consumption patterns. Instead, there was no correlation between  $\delta^{15}N$  values and grave goods. The location of burials, in terms of exclusion from the community cemetery or proximity to churches, was not linked to diet. All in all, this research allowed to characterise the foodways of otherwise unknown societies as a proxy for the understanding of their productive strategies and internal social organisation.

COOKING DEER IN THE 2ND C. BC ON THE SOUTH-WESTERN BLACK SEA COAST: PRELIMINARY RESULTS OF THE MALKOTO KALE PROJECT

**Abstract author(s):** Morand, Nicolas (Post-doc Fyssen foundation, Royal Belgian Institute of Natural Sciences) - Bastide, Maguelone (UMR 7041-ArScAn - Université Paris Nanterre) - Bogdanova, Teodora (Municipal cultural Centre, “Museum Centre - Sozopol”) - Baralis, Alexandre (Musée du Louvre, Department of Greek, Etruscan and Roman Antiquities) - Nedev, Dimitar (Municipal cultural Centre, “Museum Centre - Sozopol”)

**Abstract format:** Oral

Led by M. Bastide and T. Bogdanova, the Malkoto Kale project is carried out in the framework of the French-Bulgarian archaeological mission at Apollonia Pontica (dir. A. Baralis, K. Panayotova and D. Nedev) in collaboration with the Archaeological Museum of Sozopol (Bulgaria). The study focuses on the site of Malkoto Kale, a fortified settlement located 12 km to the South of the ancient Greek city of Apollonia, on a peak about 280 m high, partially excavated during the 1970s. The new excavation campaign of August and September 2020 has provided very interesting results. In sq. P8-Q8, the excavations revealed an important building of the Late Hellenistic period. At its SW corner, near the Southern fortification wall, we uncovered an area where various domestic activities seem to be concentrated : spinning, weaving, grinding and an uncommon way of cooking. Indeed, a fireplace associated with an amphora containing deer bones was discovered in the same area. The archaeozoological analysis proved that the deer was prepared for eating, and probably stored in the amphora. This discovery reveals an uncommon cooking of game products, in a context disturbed by military events. Moreover, the results of faunal remains studies in the city of Apollonia Pontica will enable to compare the eating practices between urban and fortified settlements during the Hellenistic period.

PLANT AND ANIMAL CONSUMPTION IN NORTHWEST IRAN DURING THE BRONZE AGE: AN INSIGHT FROM ALIABAD TEPE AND QALEH SARDAR BUKAN

**Abstract author(s):** Douché, Carolyne - Decaix, Alexia - Decruyenare, Delphine (Muséum national d’Histoire naturelle, AASPE) - Fathi, Homa - Davoudi, Hossein (University of Tehran) - Berthon, Rémi - Tengberg, Margareta (Muséum national d’Histoire naturelle, AASPE) - Djamali, Morteza (Institut Méditerranéen de Biodiversité et d’Ecologie, IMBE) - Hassanzadeh, Yousef (National Museum of Iran) - Mashkour, Marjan (Muséum national d’Histoire naturelle, AASPE)

**Abstract format:** Oral

This presentation aims to explore cooking activities in two Bronze Age sites. Excavations at Aliabad Tepe (Early Bronze Age) and Qaleh Sardar Bukan (Middle/Late Bronze Age) were carried out in the modern city of Bukan by YH (ICHHTO). The plain of Bukan is located at 1590 m asl near the Samineh rud. In both sites, archaeobotanical remains were collected. In Aliabad, cereals were found in a jar together with wild taxa, allowing discussion about agricultural and storage practices. In Qaleh Sardar, the jar contained charred grains of emmer and chickpea deposited in a domestic cooking space. Animal resources were also found in the two sites and both indicate highly specialised economies based on the exploitation of sheep and goat followed by cattle. We have the opportunity here to integrate archaeobotanical and archaeozoological results. With the two case studies, we address entangled agro-pastoral practices related to cultivation and consumption of cereals on one side and on the other herd management and consumption of animal resources within rural communities of North-West Iran, 4500 years ago. We also aim at presenting the parallels between past and modern traditional agro-pastoral systems, consumption and cooking practices. On a regional scale, we will examine the links with Uruk and Yanik cultures, the influences of which are documented in Aliabad and Qaleh Sardar archaeological material.

BUILDING PRODUCTION AND COMMERCIAL STRATEGIES: THE CASE OF THE GREAT AND SMALL PROVENÇAL ELITE (10TH - 12TH CENTURIES)

**Abstract author(s):** Unsain, Dianne (Centre Camille Jullian, A\*MIDEX, Aix Marseille Univ, CNRS, CCJ; LA3M, Aix Marseille Univ, CNRS) - Mouton, Daniel (LA3M, Aix Marseille Univ, CNRS) - Varano, Mariacristina (Université de Rouen, GRHis)

**Abstract format:** Oral

Since the study of the “peasant knights” of Lake Paladru (11th c.), the complexity of the medieval elite system has raised intense questions among both historians and archaeologists. Medieval Provence - especially in the late Middle Ages - has long raised the interest of historians. Recent advances in elite/rural archaeology and zooarchaeology have led to a certain updating of knowledge related to this context, particularly for the more remote times of the 10th - 12th centuries. Not only do they allow us to consider lords tastes and culinary practices, but they also shed light on social and economic phenomena that are still little known. This contribution will rely on three archaeological sites (rural elite settlements), their zooarchaeological analyses and on history. The results show an astonishing homogeneity in the economic and dietary behaviour of the seigniories. They are characterised by high meat consumption and by a production centred on pig breeding. On the other hand, knights, in charge of the lord lands, demonstrate intense changes in their diet and production systems, associated with the development of commercial strategies. This behaviour could be an attempt to keep the economy afloat but would not always have prevented its decline. In a broader perspective, the results can lead to (1) discussions on the fate of the medieval elites and their prospects for evolution, and (2) a reflection on the impact of social identity both on diet and on the building of a local economy.

COPROLITES: A RECORD OF FOODS CONSUMED AND THEIR PROCESSING

**Abstract author(s):** Scott Cummings, Linda (PaleoResearch Institute)

**Abstract format:** Oral

Coprolites provide an opportunity to look at diets on both the populational and personal levels. Multiple studies of coprolites from the Ancestral Puebloan cultural area in southwestern Colorado have provided the opportunity to combine assessment of the pollen, phytolith, and macrofloral records of people living in multistoried villages. Each of these proxy records provides a slightly different vision of the diet and also food preparation or processing. Many foods are represented in only one or two of these proxies, indicating the value of using multiple proxies to build a record of past diet. Examples of food consumption and preparation are varied. Consumption of green beans (Phaseolus), probably as dried, stored beans, was documented by recovery of phytoliths. Maize (Zea mays) was ubiquitous in all three proxies, while some native or gathered foods such as goosefoot (Chenopodium) were ubiquitous in only the pollen and macrofloral proxies. Cleome (beeweed) is ubiquitous in the pollen record, but absent in other records, suggesting collecting this green after it began flowering, which is typical of dual use as both a pottery paint and a green vegetable that could be cooked, stored, reconstituted, and fried.

INTRODUCTION TO THE SESSION 359: FOOD CULTURES IN ANCIENT SOCIETIES

**Abstract author(s):** Kirleis, Wiebke (Kiel University) - Kubiak-Martens, Lucy (BiaxConsult)

**Abstract format:** Oral

Food is a fundamental link that connects people across cultures and generations. Research into food cultures has long since become a key topic of ever increasing importance in social archaeology and cultural anthropology, supported by innovative natural scientific approaches on nutritional values and metabolism. Food production, processing, distribution and consumption are the pre-

conditions for the existence of human life. They shape subsistence on different spatial, temporal and social scales with culinary traditions being one important expression of human livelihood that reflects social identities and social practices. What is the economic and the social relevance of food and food procurement in ancient societies? Are diversity of food choices and changes therein linked with trends and tendencies in agrarian production and advances in agrarian technology? How do interactions between humans and food and behavioural variability influence past culinary practices? Do past dietary habits reflect social inequality and identity, and if so, how? The bringing together of multiple approaches and lines of evidence is the tool to get a better understanding of different food cultures and culinary traditions hidden in the archaeological record.

LATE BRONZE AGE DIET IN THE EASTERN BALTIC: AN EXPERIMENTAL APPROACH TO THE STUDY OF ORGANIC RESIDUES IN POTTERY

**Abstract author(s):** Podenas, Vytenis (Lithuanian Institute of History) - Luchtanas, Aleksiejus (Vilnius University) - Šapolaitė, Justina (Center for Physical Sciences and Technology) - Micelicaîtė, Viktorija (Lithuanian Institute of History) - Butkus, Laurynas - Ežerinskis, Žilvinas - Skipitytė, Raminta - Garbaras, Andrius (Center for Physical Sciences and Technology)

**Abstract format:** Oral

Ancient economic progress is widely reflected by the changes in food culture. Recently, Late Bronze Age in the Eastern Baltic has been distinguished by the active development of farming and the diminishing role of fishing in subsistence strategies.  $\delta^{13}C$  and  $\delta^{15}N$  values of charred organic residues in pottery indicate a shift towards terrestrial food sources. On the other hand, an interpretative challenge to study beyond the “terrestrial vs. aquatic” level accompanies the perpetual problem of different product representativity in the archaeological record. Therefore, an understanding of the foodstuff carbonization process in archaeological pottery helps to assess the accumulated corpus of stable isotope data. Most of which is measured in the charred macro remains that according to several experimental studies represent only the foodstuffs used in the final cooking event. However experimental data still lack tests of higher ingredient variety and the implications of their mixing process. Paper presents first results of a recently launched experimental study in which we have performed 10 cooking cycles in 11 replica pots. A variety of possible Late Bronze Age foodstuffs were used in the experiments to test the impact of C4 plant admixture, pulses effect on expected  $\delta^{15}N$  values as well as investigated the implications of sampling in different parts of the vessel. Overall, the paper presents 178 measurements of bulk carbon and nitrogen stable isotopes as well as the results of the absorbed organic residues that were extracted after the 10 cooking cycles were finished. The experimental study confirms the previous observations on macro-remains representing only final foodstuffs in plant-based recipes, however, the lasting bias were measured up to 2-3 cycles in cases of cooking fish and meat. Lastly, the study confirms the hypothesis that pulses diminish the  $\delta^{15}N$  values significantly, however they do not overshadow previous aquatic bias to an undetectable extent.

AN INVESTIGATION OF EARLY BRONZE AGE PLANT FOODS FROM ARCHONDIKO GIANNITSON, NORTHERN GREECE

**Abstract author(s):** Petridou, Chryssi - Valamoti, Soultana Maria (Lira Laboratory, Department of Archaeology, School of History and Archaeology, Aristotle University of Thessaloniki; Center for Interdisciplinary Research and Innovation - CIRI-AUTH, Aristotle University of Thessaloniki)

**Abstract format:** Oral

In the end of the 3rd millennium B.C. a fire destroyed a series of buildings at Archondiko Giannitson in northern Greece. The built space excavated at Archondiko revealed a wide range of ceramic vessels ranging from cups, serving jars, storage and cooking jars, as well as a wealth of clay thermal installations, including a specific type of a complex hearth that could be linked with sophisticated culinary practices, like beer preparation. Detailed sampling of the burnt destruction layer has yielded a wealth of archaeobotanical remains that reveal the range of plant food ingredients stored and processed for food or other purposes. A wide range of cereal crops, oil plants and plants harvested from the wild have been identified in rich concentrations. Cereal remains dominate the archaeobotanical assemblage, indicating the cultivation of a variety of cereals at Archondiko: glume wheats include einkorn, emmer, new glume wheat type T. timopheevii and spelt wheat, while the presence of free-threshing wheat (bread/durum wheat) and hulled barley is also prominent. Besides cereals, linseed and Lallelantia sp. are also found in rich concentrations, while three species of pulses, grass pea, lentil and bitter vetch, are encountered in smaller amounts. Together with the variety of stored crops, the site has also yielded a wealth of cereal food remains that reveal complex culinary practices, which are presented for the first time in a comprehensive, contextual way. This presentation offers an overview of the range of plant food ingredients used at the settlement and discusses plant foods of the 3rd and early 2nd millennia BC in the wider context of food choices and identity in Bronze Age southeastern Europe.

INVESTIGATING BIRTH DISTRIBUTION, LAMBING SEASONS AND LAMB MEAT CONSUMPTION IN MEDIEVAL PROVENÇE FROM A ZOOARCHAEOLOGICAL, HISTORICAL AND ISOTOPIC PERSPECTIVE

**Abstract author(s):** Unsain, Dianne (Centre Camille Jullian, A\*MIDEX, Aix Marseille Univ, CNRS, CCJ; LA3M, Aix Marseille Univ, CNRS) - Knockaert, Juliette (Department of Archaeology, University of York) - Burri, Sylvain (TRACES CNRS-Université Toulouse Jean Jaurès) - Magniez, Pierre (Aix Marseille Univ, CNRS, Minist Culture, LAMPEA) - Mocci, Florence (Centre Camille Jullian, Aix Marseille Univ, CNRS, CCJ) - Walsh, Kevin (Department of Archaeology, University of York)

**Abstract format:** Oral

The importance of domestic caprine in the of medieval Provence (10th-15th centuries) is no longer in doubt. Both historical and zooarchaeological research place them as the main source of meat in the cities and towns of the region. However, the latest research carried out in central Provence raises questions about the seasonality of animal breeding and their management in medieval times. Indeed, these studies came up against two contradictory visions provided, on the one hand, by zooarchaeology and the natural reproduction cycle, and on the other, by the historical sources and the religious context. The celebration of Easter has been characterised from the very beginning of Christianity (2nd century A.D.) by the consumption of lamb (and young goat) meat. The accounts of Provençal butchers in the 14th century indicate the massive consumption of suckling lamb during spring. These animals were aged between three and six weeks. However, in several elite contexts, in northern France, in England as well as in Provence, zooarchaeology reveals the high consumption of more mature lambs (three to six months). If their birth followed a natural cycle (late winter or spring), these individuals, though numerous, do not fit in with either religious habits or available textual sources. This observation leads us to consider out of season lambing. This communication aims to explore the links between livestock husbandry and cultural / religious backgrounds. For this purpose, zooarchaeology and written records, combined with the estimation of the birth seasons via oxygen isotope analyses, will allow us to discuss (a) the rhythmicity of the caprine meat products availability over the year (b) the adaptation of breeding and/or commercial practices to provide the privileged populations with top-quality products.

DIGGING IN THE SHADOWS. EXPERIMENTAL USE OF TOOLS FOR USO’S GATHERING

**Abstract author(s):** Lopez-Bulto, Oriol (Autonomous University of Barcelona - UAB) - Berihuete-Azorín, Marian (Institut Català de Paleoeecologia Humana i Evolució Social - IPHES)

**Abstract format:** Oral

Wooden digging sticks have ethnographically and archaeologically identified as a common tool between hunter-gatherer societies, being root recollection one of the main functions. Underground Storage Organs (USO’s) are indeed a very valuable food resource, predictable and reliable because of their seasonality, as well as relatively easy to gather and process. Their use and consumption are known from a variety of ethnographic and ethnobotanical investigations and literature suggests that they were widely used as food by recent hunter-gatherers. However, the use of these resources in the past has been to date undervalued for multiple reasons such as recovery issues, identification difficulties, but also due to the difficulty to identify tools involved in its gathering process.

In this work, we present an experimental program designed to corroborate the efficiency of this type of tools in the USO’s gathering process with experimental digging sticks as well as their use-wear analysis as a reference collection for future archaeological identifications.

A. ARCHAEOLOGICAL RESEACH ON FISH EATING IN THE YAYOI PERIOD IN JAPAN

**Abstract author(s):** Shiroishi, Tetsuya (Yamagata University)

**Abstract format:** Poster

Washoku (Japanese cuisine) is a dish based on rice and fish. In this presentation, I will report on the cooking culture of rice and fish in the era when rice cultivation, which is the origin of Washoku, began. The era when rice farming culture was introduced to Japan from China is called the Yayoi period (10th century BC-3rd century AD). It is the same period as the so-called Neolithic period. During the Yayoi period, Japan changed from a hunter-gatherer society to a food-producing society. Here, we report how rice and fish from the Yayoi period were cooked and eaten. As the analysis method, various methods such as experimental archaeological method, trace of use of pottery, and analysis of earthenware lipid are used. Specifically, the cooking method is estimated from the traces of use of pottery. We also analyze what we were eating from the residual lipids in the pottery. In addition, the results of cooking experiments using the actually restored pottery are shown.

B. DENTAL MACROWEAR VARIATIONS IN CHALCOLITHIC AND BRONZE AGE POPULATIONS FROM NORTH-EASTERN ROMANIA

**Abstract author(s):** Petraru, Ozana-Maria (“Alexandru Ioan Cuza” University of Iași, Faculty of Biology; Romanian Academy Iași Branch, “Olga Necrasov” Center of Anthropological Research) - Groza, Vasilica-Monica - Popovici, Mariana (Romanian Academy Iași Branch, “Olga Necrasov” Center of Anthropological Research) - Bejenaru, Luminița (“Alexandru Ioan Cuza” University of Iași, Faculty of Biology; Romanian Academy Iași Branch, “Olga Necrasov” Center of Anthropological Research)

**Abstract format:** Poster

Dental macrowear is the non-pathological loss of hard tissues on the occlusal surface of the teeth. In archaeological contexts, the loss of tooth tissues is often correlated with lifestyles, habits, and with the physical properties of the consumed food - including

preparation techniques. This study concerns the dental material (M2 second molar tooth) discovered in Chalcolithic and Bronze Age archaeological sites from North-Eastern Romania. The methodology includes semiquantitative scoring system, quantitative assessment on dentine exposure, image analysis, and multiple regression analysis. The results show an increase of dentine exposure percent (PDE) with age-ranges, but no evidence of wear variation by sex. In the linear regression analysis, the age, and the dentine exposure percent, as variables, were correlated in 20% of cases (p<0.0001). Furthermore, the multiple regression analysis revealed no differences in dental wear between Chalcolithic and Bronze Age periods, as well as between the Bronze Age cultures (i.e., Monteoru Culture and Noua Culture), when dental exposure (DE, mm2) and other variables (e.g., age, occlusal area – OA, mm2, and period) may influence the dental wear.

Therefore, apart from age, occlusal area, and period, there may be other factors including an abrasive diet, poorly food-processing techniques, that could be also considered when discussing the loss of tooth tissues in archaeological populations, especially of farmers.

This work was supported by a research grant made with financial support from the Recurring Donor Fund, available to the Romanian Academy and managed by the “PATRIMONIU” Foundation GAR-UM-2019-II-2.1-16.

C. ENAMEL HYPOPLASIA AS MARKER OF NUTRITIONAL STATUS IN A LATE BRONZE AGE SAMPLE OF HUMAN REMAINS FROM TRUȘEȘTI (ROMANIA)

**Abstract author(s):** Groza, Vasilica-Monica - Popovici, Mariana (Romanian Academy – Iași Branch, “Olga Necrasov” Center of Anthropological Research) - Petraru, Ozana-Maria (Romanian Academy – Iași Branch, “Olga Necrasov” Center of Anthropological Research; “Alexandru Ioan Cuza” University of Iași, Faculty of Biology) - Bejenaru, Luminița (Romanian Academy – Iași Branch, “Olga Necrasov” Center of Anthropological Research; “Alexandru Ioan Cuza” University of Iași, Faculty of Biology)

**Abstract format:** Poster

In this study, the authors present three cases of enamel hypoplasia, identified in a sample of human skeletons dating from Late Bronze Age (Noua Culture, 1300-1100 BC), discovered in Trușești (Botoșani County, Romania).

Enamel hypoplasia is a developmental anomaly caused by perturbations of amelogenesis, representing a nonspecific indicator of health or/and nutritional status in human populations; it is a response of the human body to physiological stress. Enamel defects have been widely used by anthropologists for the investigation of growth disruptions in the past populations, as they are indicators of disturbances during child’s developmental period.

In this study, the enamel hypoplasia was identified in one female subject (40-45 years old) and two males subjects (30-35 years old and respectively 60-65 years old); it is evaluated by stereomicroscopy and radiology. The teeth were analyzed by a Carl Zeiss Stemi 2000-C stereomicroscope with a Canon Power Shot SX70 HS attached. The identified enamel hypoplasia is of linear transversal type, on incisive, canine and premolar teeth.

This work was supported by a research grant made with financial support from the Recurring Donor Fund, available to the Romanian Academy and managed by the “PATRIMONIU” Foundation GAR-UM-2019-II-2.1-16.

D. CEREALS VS PULSES. WHICH IS MORE RESISTANT TO HIGH TEMPERATURES? DIFFERENTIAL CARBONISATION AND ARCHAEOBOTANICAL IMPLICATIONS

**Abstract author(s):** Tarongi, Miguel - Alonso, Natàlia (Universitat de Lleida)

**Abstract format:** Poster

The values of frequency and quantity of pulse seeds among the Mediterranean archaeological record are lower values than those of cereals. In spite of always assuming a secondary role in agro-food processes, it is possible that pulses are underrepresented. Although most are charred, they are also found in mineralised or waterlogged states. Numerous experimental studies with current materials have been carried out to identify the changes taking place during the carbonisation process of archaeological seeds. However, no study combining different cereal and pulse species has focused on the changes produced among each under identical conditions of time and temperature.

This study presents the findings of the carbonisation of two cereal species (Triticum durum and Hordeum vulgare) and six pulse species (Lathyrus sativus, Lens culinaris, Pisum sativum, Vicia faba, Vicia ervilia and Vicia sativa) throughout 16 firings at temperatures ranging between 180 and 420º C at intervals of 6 or 12 hours and in reducing or oxidising atmospheres. In order to quantify the changes in shape and size, each seed was measured and photographed from two viewpoints (ventral and lateral) before and after carbonisation. Subsequently, the outlines of the images were analysed by means of geometric morphometry yielding biometric and morphological data yielding mathematical coefficients using elliptical Fourier transforms.

The results reveal that cereals are more resistant than pulses to high temperatures, a fact that could evidence the over-representation of cereals in archaeological contexts where the remains are charred. This suggest that pulses played a greater role among agri-food processes and in prehistoric diets, a role not reflected by archaeological contexts due to cereal’s lower resistance during carbonisation.

E. CULINARY PRACTICES IN TRANSFORMATION: THE ANALYSIS OF FOOD CRUSTS

**Abstract author(s):** Schmidt, Leander (Institut für Ur- und Frühgeschichte, Christian-Albrechts-Universität zu Kiel; Collaborative Research Centre 1266 “Scales of Transformation - Human-Environmental Interaction in Prehistoric and Archaic Societies”) - Ku-biak-Martens, Lucy (BIAX Consult Biological Archaeology & Environmental Reconstruction) - Kirleis, Wiebke (Institut für Ur- und Frühgeschichte, Christian-Albrechts-Universität zu Kiel; Collaborative Research Centre 1266 “Scales of Transformation - Human-Environmental Interaction in Prehistoric and Archaic Societies”)

**Abstract format:** Poster

Food crusts are a valuable source of information about past culinary practices. Investigations of organic residues (also referred to as food crusts) have a strong focus on animal fat and dairy products. But in addition, food crusts reveal a hidden diversity of cultivated and wild plant food. The study of plant remains in food crusts is an advancing field of investigation. So far cereal remains, acorns and (rarely) vegetative remains were identified in food crusts. Detecting green vegetables or spices that can hardly be traced in conventional macrobotanical archives, is still a desideratum.

Diachronic shifts of culinary practices from the Northern Neolithic to the Northern Bronze Age are in the focus of our project “Dynamics of Plant Economies in Ancient Societies” in the Collaborative Research Centre 1266 “Scales of Transformation - Human-Environmental Interaction in Prehistoric and Archaic Societies”. In this project, we use SEM technology for the study of food crusts as a powerful tool for the observation of anatomical structures relevant for the determination of archaeobotanical specimens. For referencing the archaeobotanical results in ancient food crusts, we apply an experimental approach by conducting cooking experiments to determine the formation processes of food crusts. In addition, we analyse amorphous lumps of charred processed food material from archaeobotanical samples.

General questions are whether a diversified crop spectrum with new crops like broomcorn millet (*Panicum miliaceum*) offered the opportunity of preparing and consuming a diversified cuisine and if the consumption of these crops was a trigger or a consequence of increased social diversity. Especially we aim at inferring ancient cooking practices and food recipes and to understand how culinary practices and choices of foodstuff are affected by, or interlinked with transformations in Neolithic and Bronze Age societies and if and how this is mirrored in food crusts.

360 ROCK ART TECHNOLOGY: THEORETICAL AND METHODOLOGICAL APPROACHES. PART 1

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Santos da Rosa, Neemias (University of Barcelona) - Zotkina, Lydia (Institute of Archaeology and Ethnography of Siberian Branch of Russian Academy of Sciences)

**Format:** Regular session

Rock art can be understood as a communication system that, through the representation of images, allows the transmission of specific information to observers who know the norms of the graphic code. Examples of this prehistoric cultural manifestation can be found throughout Europe, both in the depths of Paleolithic caves, as in the Franco-Cantabrian region, and open-air sites, such as those found in the Alps region or in Scandinavia. Since the beginning of rock art studies, in the late 19th century, technology has remained a marginal issue, often being considered as an element linked to the mere description of figures and not precisely as a research problem. Faced with this reality, in this session we intend to discuss technical and economic aspects of technological processes that led to the materialization of rock art, in order to contribute on the construction of consistent theoretical and methodological frameworks applicable to the study of different types of prehistoric visual representations around the world. Since rock art production is usually oriented towards the elaboration of tools, paint, and images –according to norms deeply related to specific social and symbolic contexts– we intend to present case studies related to all stages of the technological process, from raw materials procurement strategies to the selection of the bedrock and the manufacture, use and discard/abandonment of the elements involved in the various stages of each chaîne opératoire. Thus, submissions will be welcome on a variety of topics, including: archaeometric studies on the provenance and composition of pigments; experimental and/or traceological approaches on the technical procedures of rock art production; discussions on the relevance of landscape in the rock art chaîne opératoire; and ethnographic perspectives on the symbolic aspects of the rock art technology.

ABSTRACTS:

1 THE TECHNOLOGY OF THE NON-FIGURATIVE RED PAINTINGS FROM EL CASTILLO CAVE, SPAIN: INVASIVE AND NON-INVASIVE ANALYSIS

**Abstract author(s):** Dayet, Laure (Travaux et Recherches Archéologiques sur les Cultures, les Espaces et les Sociétés, UMR5608 CNRS-Université Toulouse Jean Jaurès) - d’Errico, Francesco (PACEA, Préhistoire, Paléoenvironnement, Patrimoine, UMR 5199 CNRS-Université de Bordeaux; Department of Archaeology, History, Cultural Studies and Religion, University of Bergen) - García Díez, Marcos (Department of Prehistory, Ancient History and Archaeology. Complutense University of Madrid) - Pitarch Martí, Africa (PACEA, Préhistoire, Paléoenvironnement, Patrimoine, UMR 5199 CNRS-Université de Bordeaux; Seminari d’Estudis i Recerques Prehistòriques - SERP, Departament d’Història i Arqueologia, Universitat de Barcelona) - Zilhão, João (Seminari d’Estudis i Recerques Prehistòriques - SERP, Departament d’Història i Arqueologia, Universitat de Barcelona; Institució Catalana de Recerca i Estudis Avançats - ICREA)

**Abstract format:** Oral

With the expansion of archaeometric studies and in situ non-invasive analytical methods, a renewal of technological studies is being observed in rock art. However, in European cave art, the study of paint technology is hampered by conservation regulations. Furthermore, in situ analyses have several limitations that have already been discussed in detail in the literature. The technology of non-figurative red paintings in European cave art thus remains poorly investigated in comparison with other Paleolithic depictions such as black animal representations. Some of the red disks and hand stencils from El Castillo Cave are among the earliest known cave paintings. They constitute a major cultural heritage from the Palaeolithic and are inscribed on the UNESCO World Heritage List. Here, we combined non-invasive and minimally invasive methods to study the composition and the technological features of the red non-figurative paintings of El Castillo. We carried out microscopic, elemental (SEM-EDS) and mineralogical (XRD, Raman spectrometry) analysis of a few micro-samples along with in situ microscopic and elemental (XRF) analysis of a wide range of red paintings. We compared the results obtained with observations derived from experimental replication for methodological and technological inferences. Non-invasive XRF analyses provide minimal information despite the application of several signal processing methods. Fe-based pigments are identified. Fe content is sometimes correlated with As and Mn contents. The analysis of the micro-samples suggest that Mn likely comes from secondary recrystallizations or repaints. SEM-EDS results show that at least two paint recipes were prepared. This difference could relate with ergonomic constraints and suggest that the red disks correspond to an accumulation through time of panels made by different persons who shared neither the same technical know-how nor, very possibly, the same symbolic system.

2 A MULTI-TECHNICAL ANALYTICAL APPROACH FOR THE STUDY OF LEVANTINE AND SCHEMATIC PAINTINGS AT EL CARCHE ROCK ART SITE (JALANCE, SPAIN)

**Abstract author(s):** Chieli, Annalisa (Fundació Bosh i Gimpera/Universitat de Barcelona//LArchHer, Department of History and Archaeology) - Domingo, Inés (ICREA, Universitat de Barcelona, SERP, Department of History and Archaeology) - Vendrell, Marius - Giráldez, Pilar (Patrimoni 2.0 Consultors)

**Abstract format:** Oral

In this presentation, we assess the results of the multi-technical non-destructive analysis of several Levantine and Schematic paintings from el Carche rock shelter (Jalance, Spain). Optical Microscopy, Scanning Electron Microscopy coupled with Energy Dispersive X-Ray Spectroscopy (SEM-EDS), Raman Spectroscopy and Fourier Transform Infrared Spectroscopy (FTIR) have been combined to identify the pigments, the pictorial techniques and recipes characterizing the paintings of both Levantine and Schematic motifs sharing this site. Our aim was to identify similarities and differences both between and within each artistic tradition. The analyses conducted on the micro samples both as free fragments and as embedded cross-sections have provided evidence of different paint recipes characterized by the use of diverse raw material. Moreover, the microstratigraphic investigation highlighted the presence of diverse degradation products and external crusts related to rock alteration processes, that also occur and co-exist within the pictorial layer. The current research demonstrates the importance of using several and complementary analytical techniques when investigating highly complex and heterogeneous samples, such as those taken from rock art paintings where, apart from the pictorial layer, other components are usually contained, including the bedrock, biological patinas, alteration products, and crusts. This research has been conducted as part of the ERC CoG LArchHer project (grant agreement No 819404).

3 RED OCHRE OR SOMETHING ELSE? GEOCHEMICAL TESTS ON FINNISH ROCK ART PAINTS

**Abstract author(s):** Kailamaki, Uine - Holmqvist-Sipilä, Elisabeth (University of Helsinki) - Vajanto, Krista (Nanomicroscopy Center of Aalto University) - Lahelma, Antti (University of Helsinki)

**Abstract format:** Oral

Finnish rock paintings can be seen as a part of a larger northern hunter-gatherer rock art tradition. The red paintings depict stylized animals, humans, boats and geometric patterns painted on steep rock surfaces near ancient waterways. They have been preserved by naturally accumulating silica glazes, and based on shore displacement chronology they are typically associated with Subneolithic northeast European Pit-Comb Ware cultures.

ANOTHER RAW MATERIALS IN RECEIPT OF OCHRE ON ROCK PAINTINGS OF EASTERN PAMIR?

**Abstract author(s):** Solodeynikov, Alexey (Museum-reserve “Shulgan-Tash cave”) - Zotkina, Lydia (Institute of Archaeology and Ethnography SB RAS) - Abolonkova, Irina (“Tomskaya Pisanitsa” Museum-Reserve)

**Abstract format:** Oral

Working with painted rock art images from Kurteke site, situated in East Pamir, we found, that some results of the Pigment Maps analysis of some images do not answer to our expectations. The Pigment Map analysis is a digital method of revealing of faded images, based on increasing contrast in a very thin area of color data of the image [Solodeynikov, 2005]. When working with Lab system we usually have commensurable signals in different color channels of the color space. For some pictures, from Kurtike we have different situation: signal in b channel is inverted relatively to the signal in a channel. Signals, which are correlated in color channels of the Lab color space, we usually consider to be evidences of quantity disparity between iron oxides and iron hydroxides. But results of our expertise with images such as in Kurteke rock art site make us suppose presence of a large amount of manganese oxides in the pigment as long as we have strong bluish component, while iron hydroxides have yellowish coloration. That would mean that we probably have the paint, which was prepared from another raw materials, than usual ochre. We began series of experiments and analysis in order to proof or to refute this. If our assumption of correlation between chemical composition and results of the Pigment Map analysis is true, then the Pigment Map analysis became an instrument useful not only in revealing faded rock art images, but it can be used for some basic components analysis also. It is important considering that Pigment Map analysis is non-destructive method of research, which doesn't need any expansive special equipment.

Solodeynikov A. 2005. Research on the Recordings of rock paintings in the Kapova cave (Ural). // INORA 43,10-14.

TOOLS, PIGMENTS AND BINDERS: AN EXPERIMENTAL APPROACH TO LEVANTINE ROCK ART TECHNOLOGY

**Abstract author(s):** Santos da Rosa, Neemias (University of Barcelona) - Fiore, Danae (Consejo Nacional de Investigaciones Científicas y Técnicas - CONICET; University of Buenos Aires) - Viñas, Ramon (Institut Català de Paleoecologia Humana i Evolució Social - IPHES)

**Abstract format:** Oral

Identified in more than a thousand open-air shelters in eastern Spain, the Levantine rock art is a singular cultural manifestation of European prehistory. Since its discovery, several proposals have been elaborated on the technological process that underlies the creation of the images. However, most of them are based on theoretical criteria and on inductive reasoning, which so far had not been rigorously tested. In this context, we have surveyed all these proposals and considered them as hypotheses, which have been tested by means of an experimental archaeology protocol related to the production and use of tools and paints and the creation of images with technical characteristics similar to those of the Levantine representations. During these systematic experiments, we analyzed the efficiency of 112 pictorial recipes made through the combination of 6 pigments and 11 of binders, and 63 paint application tolls produced with different types of feathers, hairs, and plants. Besides, we reproduced full-scale replicas of some archaeological models to understand the technical and economic aspects involved in the production of the images. This paper presents the results of our experimental research and a series of empirically-based inferences about Levantine rock art technology.

MICROPHOTOGRAMMETRY APPLICATION TO THE TECHNO-TRACEOLOGICAL STUDY OF ENGRAVINGS. THE CASE OF ATXURRA CAVE (NORTHERN SPAIN)

**Abstract author(s):** García Bustos, Paula - Rivero Vilá, Olivia (Universidad de Salamanca) - Ríos-Garaizar, Joseba (Centro Nacional de Investigación en Evolución Humana) - Intxaurbe, Iñaki (Universidad del País Vasco) - García Bustos, Miguel (Universidad de Salamanca) - Garate Maidagan, Diego (Universidad de Cantabria)

**Abstract format:** Oral

Traceological studies in Palaeolithic rock art have focused all their efforts on recognizing the gestures and technology involved in making the artistic motifs. Currently, with the progress of new technologies, it is possible to encode the data obtained through digital photography in three dimensions, analyzing them with greater ease and scientific rigor.

The purpose of this research is to recognize the types of sections of the Upper Magdalenian parietal engravings of the “Ledge of the Horses” in Atxurra Cave, and correlate this data with the lithic tools located in. To do this, we have developed an experimental program, microscopic analysis and the application of the macrophotogrammetric technique, replicating the information in 3D to identify morphological and metric parameters of engravings. The statistical analysis of the results obtained allows associating the characteristics recognized in the incisions with the tools that were discovered in the excavations at the foot of the panel where the engraved animals are.

INSTRUMENTS AND WEAPONS OF THE TAGAR CULTURE AS TOOLS FOR PICKETAGE: USE-WEAR ANALYSIS

**Abstract author(s):** Davydov, Roman (Laboratory of Paleotechnologies, Institute for the Humanities, Novosibirsk State University)

**Abstract format:** Oral

The Tagar archaeological culture (Southern Siberia, 7-3 centuries BC) is characterized by rock arts made using the pecking technique. One of the areas of research of rock art is technological-traceological study, in particular, the identification of tools. For the Tagar archaeological culture such tools could be not only stone, but also metal.

In the collection of the Minusinsk Museum, bronze tools and some weapons of the Tagar culture were examined. They have traces of use and a shape suitable for pecking. Based on the published datas on the Tagar metal composition and technology of casting, 11 replicas of copper and bronze tools were cast: points, hastate chisels, chisels, sagarises, hammers. They were processed with stone and bronze metalworking tools typical for the Bronze Age and the Early Iron Age.

Together with Ph.D. Zotkina L.V. a series of experiments was carried out, which consisted of working with tools on a rock of reddish Devonian sandstone in the techniques of direct and indirect pecking (a total of 36 cycles, including updating the working surfaces).

Traces of wear were obtained on experimental tools. These are flattening with a stone micro-relief on the points and blades, accompanied by metal protrusions along the edges. With indirect picketing, the striking platform is flattened. There are traces of impact stone or metal tools and delamination due to work-hardening. Patterns between blade tilt, deformation of the striking platform and the angle relative to the rock were revealed. The features of wear for each type of metal were captured.

Comparison of the traces made it possible to record the wear from the making of petroglyphs on some pointed universal tools in the form of bronze rods. Such marks are present on some hastate chisels. On sigarises and chisels, wear is of a different origin.

THE ROCK ART PRODUCTION IN THE ROMANELLI CAVE (SOUTHERN ITALY)

**Abstract author(s):** Sigari, Dario (Dipartimento di Studi Umanistici, Sezione Scienze Preistoriche e Antropologiche, Università degli Studi di Ferrara; Geosciences Center, Coimbra University) - Ranaldo, Filomena (Museo della Preistoria di Nardò; Dipartimento di Scienze Fisiche, della Terra e dell’Ambiente, U.R. Preistoria e Antropologia, Università degli Studi di Siena) - Mazzini, Ilaria (IGAG-CNR, Monterotondo - RM) - Forti, Luca (Dipartimento di Scienze della Terra “Ardito Desio”, Università degli Studi di Milano; IGG-CNR) - Bona, Fabio (Dipartimento di Scienze della Terra “Ardito Desio”, Università degli Studi di Milano) - Mecozzi, Beniamino (Dipartimento Scienze della Terra, Sapienza Università di Roma; Laboratorio PaleoFactory, Dipartimento Scienze della Terra, Sapienza Università di Roma) - Lembo, Giuseppe (Associazione Culturale Archeoldea, Campobasso) - Muttillo, Brunella (Dipartimento di Studi Umanistici, Sezione Scienze Preistoriche e Antropologiche, Università degli Studi di Ferrara; Associazione Culturale Archeoldea, Campobasso) - Sardella, Raffaele (Dipartimento Scienze della Terra, Sapienza Università di Roma)

**Abstract format:** Oral

During the latest research activities in the Romanelli Cave -a site studied since the beginning of XX Century- in the Salentine Peninsula (southern Italy), 27 new Graphical Units were recorded. Such a record has led to new significant results on the Palaeolithic rock art heritage of this site. The walls and ceiling of the cave had been decorated over a long period of time, during which the morphology of the cave had changed as well. Rock art techniques changed according to the changes of the support properties, showing the artists’ skills in choosing different tools depending on the natural features of the rock surface. In the moonmilk, we identified digital flutings, while on other rock surfaces large and thin grooves were possibly produced by different tools or by the same tool used in different ways. Moreover, the ongoing excavation just below the decorated panels has already brought to light the lithic tools probably used to engrave the cave walls.

ENGRAVINGS, ROCKS AND USE-WEAR ANALYSIS: AN EXPERIMENTAL APPROACH

**Abstract author(s):** López-Tascón, Cristina (Universidad de Oviedo)

**Abstract format:** Oral

In this communication, I present a study about the experimental reproduction of engravings combined with a use-wear analysis approach. The rock selected for experimentation was Caliza de Montaña, rock present in the walls of most Paleolithic art sites situated along the Nalón river (central area of Asturias, North of Spain). Experimentation has allowed checking the hardness of rock, some techniques to reproduce the engravings, the sections produced, and different tools flint employed to engrave. Also, this study presents a use-wear approach to analyse experimental tools used in the reproduction of parietal limestone engravings. The main objective of this study consists of checking if these lithics tools present use-wear traces and if it is possible to characterise and define them.

This study provides a new vision of the tools found in sites with parietal art that must be combined with the traditional interpretations focused on typological and stylistic approaches, and on the analysis of formal aspects and motifs engraved. The method developed helps better understand the relationship between engraved walls and human occupation of caves, rock shelters and open-air sites with parietal art.

PIGMENT APPLICATION TECHNIQUES IN PRE-MAGDALENIAN PORTABLE ART FROM PARPALLÓ CAVE, GANDÍA, SPAIN

**Abstract author(s):** Rosso, Daniela (Departamento de Prehistoria, Arqueología e Historia Antigua, Grupo de Investigación Prehistoria del Mediterráneo Occidental - PREMEDOC, University of Valencia; CNRS - CEPAM UMR 7264, Université Côte d’Azur) - Cantó, Ana (Departamento de Prehistoria, Arqueología e Historia Antigua, Grupo de Investigación Prehistoria del Mediterráneo Occidental - PREMEDOC, University of Valencia) - Roldán García, Clodoaldo - Murcia Mascarós, Sonia (Institute of Material Science - ICMUV, University of Valencia) - Villaverde Bonilla, Valentín (Departamento de Prehistoria, Arqueología e Historia Antigua, Grupo de Investigación Prehistoria del Mediterráneo Occidental - PREMEDOC, University of Valencia)

**Abstract format:** Oral

Parpalló Cave yielded one of the most important collections of Palaeolithic portable art, consisting of 5612 limestone plaquettes painted and/or engraved with animal figures and non-figurative signs. The plaquettes were recovered throughout the entire sequence, covering a period of 15.000 years, from the Gravettian to the Magdalenian (26.000–11.000 years BP), thus providing a unique opportunity to study the evolution through time of mobiliary art production. In the past few years, portable art from Parpalló Cave has been the object of numerous studies that mainly focused on stylistic or thematic aspects and pigment characterisation. However, little is known about the technological processes involved in their manufacture. Our aim here is to study the techniques used to produce painted figurative motifs (n=81), most of which were found in pre-Magdalenian levels at Parpalló Cave. By contrasting archaeological evidence and experimental data, this study will shed new light on the complexity of painted mobiliary art production at Parpalló Cave, particularly during the pre-Magdalenian period. In the future, this will allow us to compare pigment application techniques used in mobiliary and parietal art during this key period for the development of Palaeolithic art.

MANUFACTURING PAINTED PORTABLE ART: AN EXPERIMENTAL APPROACH

**Abstract author(s):** Cantó, Ana (Dpto. de Prehistòria, Arqueologia i Història Antiga, Universitat de València. PREMEDOC) - Rosso, Daniela Eugenia (Dpto. de Prehistòria, Arqueologia i Història Antiga, Universitat de València. PREMEDOC; CNRS - CEPAM UMR 7264, Université Côte d’Azur) - Roldán García, Clodoaldo - Murcia Mascarós, Sonia (Institute of Material Science - ICMUV, University of Valencia) - Villaverde, Valentín (Dpto. de Prehistòria, Arqueologia i Història Antiga, Universitat de València. PREMEDOC)

**Abstract format:** Oral

In recent years, experimental approaches to the analysis of Palaeolithic art have been widely developed in the literature. However, few studies focus on pigment application techniques used for the manufacture of painted portable art. Evidence recovered in the Upper Palaeolithic levels of Parpalló Cave, Gandía, Spain, shows that painted plaquettes were produced using a variety of techniques that were never studied in detail. Here we present results obtained during our first experimental sessions. We used different techniques to apply ochre-rich compounds on experimental limestome plaquettes recovered in the surroundings of the cave, focusing on three main phases of the painted plaquette chaîne opératoire: (1) the preparation of the support before the application of pigment, (2) the production of pigment compounds of different densities and textures and (3) the application of pigment compound using a variety of techniques and tools. By using this experimental approach, we will we hope to be able to better understand the complexity and variety of technological processes involved in the creation of painted portable art.

ROCK ART TECHNOLOGY: THEORETICAL AND METHODOLOGICAL APPROACHES. PART 2

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Santos da Rosa, Neemias (University of Barcelona) - Zotkina, Lidia (Institute of Archaeology and Ethnography of Siberian Branch of Russian Academy of Sciences)

**Format:** Regular session

Rock art can be understood as a communication system that, through the representation of images, allows the transmission of specific information to observers who know the norms of the graphic code. Examples of this prehistoric cultural manifestation can be found throughout Europe, both in the depths of Paleolithic caves, as in the Franco-Cantabrian region, and open-air sites, such as those found in the Alps region or in Scandinavia. Since the beginning of rock art studies, in the late 19th century, technology has remained a marginal issue, often being considered as an element linked to the mere description of figures and not precisely as a research problem. Faced with this reality, in this session we intend to discuss technical and economic aspects of technological processes that led to the materialization of rock art, in order to contribute on the construction of consistent theoretical and methodological frameworks applicable to the study of different types of prehistoric visual representations around the world. Since rock art production is usually oriented towards the elaboration of tools, paint, and images –according to norms deeply related to specific social and symbolic contexts– we intend to present case studies related to all stages of the technological process, from raw materials procurement strategies to the selection of the bedrock and the manufacture, use and discard/abandonment of the elements involved in the various stages of each chaîne opératoire. Thus, submissions will be welcome on a variety of topics, including: archaeometric studies on the provenance and composition of pigments; experimental and/or traceological approaches on the technical procedures of rock art production; discussions on the relevance of landscape in the rock art chaîne opératoire; and ethnographic perspectives on the symbolic aspects of the rock art technology.

ABSTRACTS:

SCRATCHING THE SURFACE OF SCOTLAND’S ROCK ART: A HOLISTIC, MULTISCALAR ANALYSIS OF LOCATION AND DESIGN THROUGH LOCAL CASE STUDIES

**Abstract author(s):** Bjerketvedt, Linda - Valdez-Tullett, Joana - Barnett, Tertia (Historic Environment Scotland) - Jeffrey, Stuart (School of Simulation and Visualisation, Glasgow School of Art) - Robin, Guillaume (School of History, Classics and Archaeology, University of Edinburgh)

**Abstract format:** Oral

The term Atlantic Rock Art (ARA) refers to a widespread open-air rock carving tradition located along the Atlantic seaboard (Bradley 1997; Valdez-Tullett 2019). Broadly dated to the Neolithic and Early Bronze Age, in Scotland these carvings tend to be abstract and geometric, usually taking on circular shapes in the form of cupmarks and concentric rings (known as cup-and-ring motifs), as well as other circular variations. They occur on boulders and outcrops across the country – albeit unevenly distributed – usually on rock surfaces that are flush with the ground or gently sloping. Although this carving tradition is quite homogenous, previous research, based on a detailed analysis of ARA’s chaîne opératoire, has shown that there are regional variations in terms of the motifs, their relationship with the rock surfaces, the selected rocks and even landscape locations (Valdez-Tullett 2019). In the course of Scotland’s Rock Art Project we have surveyed large areas of the country and have confirmed the occurrence of these local preferences.

This paper will explore ARA’s regional variations in Scotland further, focusing on its chaîne opératoire and the reasons that may underpin these patterns of rock art production. We will discuss our multiscalar approach to looking at the motifs, the boulders and outcrops and landscape features, and how these may have impacted decision-making. In our approach we studied a number of cultural and natural variables, from the small details of motifs and carving techniques, to the rock’s microtopography and landscape analysis (e.g. viewshed and mobility patterns, relationship with other sites, geology). We applied this approach to five case-studies across Scotland in order to sample the regional variations. This analytical approach provided a better comprehension of the similarities and differences within Scottish rock art, which enabled us to characterise the decision-making underpinning the placement of these carvings within the landscape.

ACOUSTICS AND THE CHAÎNE OPÉRATOIRE OF ROCK ART PRODUCTION: LEVANTINE ROCK ART AS A CASE STUDY

**Abstract author(s):** Díaz-Andreu, Margarita (ICREA; Universitat de Barcelona) - Santos da Rosa, Neemias - López-Mochales, Samantha (Universitat de Barcelona)

**Abstract format:** Oral

The selection of a location in which to paint or carve is a fundamental step in the chaîne opératoire related to the production of rock art. It has been argued that in many cases the geological and topographical features of shelters played a crucial role in the decision of prehistoric artists regarding where to place their visual representations. In this paper we assess whether other factors whose evidence cannot be detected by traditional archaeological methods may also have influenced such a decision. We present the results of the archaeoacoustics fieldwork undertaken at 31 Levantine rock art sites located in Catalonia (Spain) in the framework of the ERC Artsoundscapes Project (www.ub.edu/artsoundscapes). Using the Impulse Response (IR) methodology, a series of monaural and

3

binaural acoustic parameters were measured. The results have allowed us to examine the possible relationship between specific rock art motifs and particular sonic environments. The statistical analysis of the data indicates that archer figures were painted in shelters with higher Strength (G) values. We discuss how to interpret that shelters where a greater sensorial impact of sound was experienced were chosen to paint masculine figures. Finally, we reflect on what the possible creation of masculine soundscapes may tell us about the chaîne opératoire in Levantine rock art production.

3 FINGER FLUTINGS IN KAPOVA CAVE

**Abstract author(s):** Solodeynikov, Alexey (Museum-reserve “Shulgan-Tash cave”)

**Abstract format:** Oral

Kapova cave is situated in South Ural, on the border between Asia and Europe. In 2019 we discovered there some images made with fingers on soft substratum: mondmilch, derated limestone, or some clay deposits. The finger-made images in other caves in France can be figurative, representing some animals, geometrical signs or human’s depictions or they can be just lines, made with obviously non-artistic purpose. Those in Kapova in most cases seem to be representations of animals: horses, aurochs, mammoths, deer. The images in Kapova are made using intricate relief of the rock, which in addition with very thin traces makes them very hard to observe and to document. The finger flutings appear to be the most complicated subject to investigate, as long as there are no contact methods of documenting could be applied. In this report we are going to share our two seasons’ experience in investigating of, probably, the most difficult subject in rock art studies.

4 ABRI DU POISSON: SALMON’S LIFE

**Abstract author(s):** Zotkina, Lydia (Institute of Archaeology and Ethnography of SB RAS; ArchaeoZOOlogy in Siberia and Central Asia - ZooSCAN”, CNRS – IAET SB RAS International Research Laboratory, IRL2013) - Cretin, Catherine (National Museum of Pre-history - MNP, Les Eyzies de Tayac) - Maury, Serge (-)

**Abstract format:** Oral

Everyone knows one of the greatest prehistoric art masterpieces in Franco-Cantabrian region the famous fish from abri du Poisson. It is a bit more than 1 m long quite realistic bas-relief representation of male salmon in spawning period. The story of attempt to steal the depiction is well known too.

But what do we know about salmon’s creation and its “life” during thousands of years?

First of all to reconstruct the whole story we must understand the processes that have taken place in the rock shelter. During the excavations in the beginning of the XXth century two archaeological layers (Aurignacien and Gravettian) were discovered on the site. Later in 2018 this data was confirmed by stratigraphy cleaning. That means that most probably the bas-relief was created in one of those periods.

Even if the salmon depiction is the most famous there are other figurative and non-figurative expressions on the site. If we take a look on the vault we can see numerous degraded lines and even sometimes representing partly preserved figures. One of them is still visible under the salmon. Other interesting elements are perforated rings (anneaux percés) which are numerous on the vault and which are represented on the salmon figure as well.

In this paper we are trying to take into account all of these elements and to find convincing arguments to reconstruct the “life-story” of the fish depiction and of other imagery on the site.

5 UNRAVELING SOCIAL INVESTMENT AND COST PRODUCTION IN PALAEOLITHIC ROCK ART

**Abstract author(s):** Garate, Diego (Universidad de Cantabria) - Rivero, Olivia (Universidad de Salamanca) - Arriolabengoa, Martn (Universidad del País Vasco) - Medina-Alcaide, María (Universidad de Córdoba) - Intxaurbe, Iñaki (Universidad del País Vasco)

**Abstract format:** Oral

Parietal graphic representations are perhaps the most astounding of all the creations of hunter-gatherer groups during the Upper Palaeolithic. From the point of view of scientific research, the archaeological study of this graphic activity potentially goes beyond artistic creation in itself. The anthropisation of caves with graphic representations undoubtedly goes further than the production of the parietal depictions and encompasses many other kinds of actions, both voluntary and fortuitous, such as the thermal alteration of endokarst surfaces, impressions of anatomical parts or objects, geomorphological changes to the natural space, the extraction of raw materials and the deposition of different kinds of materials. Each of these actions is materialised in the archaeological remains documented in the sites.

The interdisciplinary study of this evidence of human activity inside the caves provides a great deal of information including, among other aspects: the time when the prehistoric groups entered the cave; the appearance of the anthropised karst setting and how they moved through the cave; the fuel used for lighting, its duration and the power it provided; the sex, age or pathologies of the creators of the depictions; the materials they carried and the use they made of them inside the caves; etc.

This comprehensive perspective of rock art can be assumed through the economic value and degree of complexity derived from the symbolic actions, establishing all the different operative chains that intervened in the artistic creation. In this way, we can reconstruct the material, human and time resources devoted to symbolic activity inside the caves by their authors. Ultimately, this

research attempts to appraise the social importance of these activities, as a determining factor to comprehend the structure and organization of Paleolithic societies.

6 RHYTHM, RELATIONAL TECHNOLOGY, AND HISTORY: EXPLORING ROCK ART PRODUCTION IN NORTH-CENTRAL CHILE

**Abstract author(s):** Troncoso, Andres (Universidad de Chile) - Moya, Francisca (SERP/Departament d ’ Historia i Arqueologia, Universitat de Barcelona) - Armstrong, Felipe (Universidad Alberto Hurtado) - Vergara, Francisco (Universidad Austral de Chile - Puerto Montt)

**Abstract format:** Oral

Archaeological approaches to rock art technology have proven to be a fruitful analytical framework to understand the processes through which rock art emerges. Although these studies have enriched our interpretations and characterization of rock art, they have focused mainly on the identification and characterization of tools in the case of engravings (Álvarez & Fiore 1995; Bednarik 1998) and pigmentarian matters in rock paintings (Chalmin & Huntley 2018). As a result, these studies have scarcely discussed the engagements between technology, rock art production and socio-historical processes. In fact, worlds inhabited by human beings are always historical and technology is a way of worlding. From such perspective, rock art technology is a particular way of worlding which unfolds particular affective and agentive qualities of images, materials and places. Considering the above, we explore rock art technology from a historical perspective, considering two qualities scarcely explored in these kinds of studies: the rhythmic, and relational nature of the making process. Both qualities allow us to understand the historical character of rock art, its particular affective qualities and how rock art unfolded historical worlds through the process of making. To do so, this paper explores three sets of rock art identified for the Elqui and Limarí Rivers basins in North-Central Chile, produced at different times between the Late Archaic Period characterized by hunter-gatherer contexts (ca. 3000 BCE - 500 CE) and the moment of Inka occupation (ca. 1470-1540 CE). This work is part of the FONDECYT 1200276 research project.

7 SOUND, RITUAL AND ARCHAEOLOGICAL ONTOLOGIES: EXPLORING THE SYMBOLIC DIMENSIONS OF ROCK ART PRODUCTION AND USE IN PREHISTORY

**Abstract author(s):** Santos da Rosa, Neemias (University of Barcelona) - Jiménez Pasalodos, Raquel (University of Valladolid; University of Barcelona) - Díaz-Andreu, Margarita (Institutió Catalana de Recerca i Estudis Avançats - ICREA; University of Barcelona)

**Abstract format:** Oral

For more than a century, rock art research has been carried out mostly according to image-centred Western ontologies, ignoring the importance of sensorial perception for prehistoric societies. The way of being in the world of those who produced and used rock art was based on a very different logic to that on which scholars are positioned. Most likely, in the relational world of ancient communities, images were not the only relevant element in rock art. The development of ritualistic behaviours during art production could make the technological process of creation as symbolic and meaningful as the representations themselves. Sound is a fundamental component of ritual practices and acoustic effects such as resonance, reverberation and echoes may have been effective means to boost perceptual experiences involving speech, dance, and music as well as silence. In this paper, we propose that archaeoacoustics research is an efficient way to obtain empirical evidence about possible ritual activities related to the creation and consumption of rock art in prehistory. We support such a proposal presenting results of our acoustic fieldworks in rock art landscapes of Mediterranean Spain, Baja California (Mexico), and Siberia (Russia). Based on this data, we advocate for the adoption of relational ontologies that allow us to expand the scope of our interpretations not only of rock art but also of the prehistoric technologies involved in its creation.

8 TECHNOLOGICAL FEATURES IN ROCK ART OF MINUSINSK BASIN (SOUTH SIBERIA): ARE THEY INDICATORS OF STYLISTIC TRADITIONS?

**Abstract author(s):** Zotkina, Lydia (Institute of Archaeology and Ethnography of SB RAS)

**Abstract format:** Oral

Minusinsk basin is known as one of the greatest rock art regions in Siberia. Stylistic traditions of different periods from Neolithic to Ethnographic times are represented here. Great amount of imagery have been attributed to different cultures with discovering typical examples of depictions in reliable archaeological context, like Okunev (Early Bronze age), Tagar (scythian period, Early Iron age), Tashtyk (Xiongnu, Iron age) cultures. However, there are many petroglyphs that do not have conventional cultural or even chronological attribution, such as the so-called “earliest”. All the researches accept that this rock art is older than Okunev Early Bronze age imagery which is quite specific. But for the moment the “earliest” petroglyphs are still not dated.

When traceology of petroglyphs first appeared as a new field of study one of the main challenges was identification of using lithic or metal tools in creation of rock art. This could be useful for consequential chronological attribution. And as approach it remains applicable. But in some regions, for example in Minusinsk basin, the increased use of metals and, which is important, of high quality metals is occurred in Scythian period. So it is much later than the “earliest” petroglyphs were performed.

That is one of the reasons why we have to concentrate on other technological features which could be significant to identification of different stylistic traditions.

If in flint knapping chaîne opératoire is one of the most stable phenomena in any material culture. Could the technological sequences in rock art be stable too? And if so could we reveal special features which identify different imagery concepts?

The research is supported by Foundation of the President of RF MK-2273.2020.6.

### PORTABLE ART AND OBJECT-ORIENTED RELATIONS IN THE CULTURAL LANDSCAPE FROM TECHNOLOGICAL PROSPECTIVE: THE CASE OF KAMYANA MOHYLA

**Abstract author(s):** Radchenko, Simon (New archaeological school; University degli studi di Torino) - Kiosak, Dmytro (Ca' Foscari University of Venice)

**Abstract format:** Oral

The cases, when the special cultural contexts emerge out of common environmental setting, are well-known for Late Mesolithic societies of Eastern Europe. Those from the Southern Ukraine living on the banks of Molochna River can be an example. The innovative fishing-oriented Late Mesolithic societies that lived nearby the sandstone mound of Kamyana Mohyla found themselves in a special landscape that affected their being from cultural perspective. Since Kamyana Mohyla is the only rock art site in the region, it is clear that the social processes here have been shaped by special landscape conditions, which formed the basis for cultural landscape appearance. The mound full of caves forced the emergence of beliefs later reflected in the parietal art instances here.

Moreover, the desire to communicate with this cultural landscape forced the population living nearby to interconnect with the special things, namely fish-like shaped churingas (portable art objects). The latter were found both inside Kamyana Mohyla caves and in the Hill's surroundings and are simultaneously part of cultural landscape, the objects of human-landscape interaction and things, that interconnected both with Kamyana Mohyla population and the unique cultural landscape; thus, these objects correspond to the basic ideas of object-oriented ontologies. However, their relationship with the human beings is reflected in the engravings and notches on their surface, their shape, size and location. All of these data is the sources of information concerning the technological aspect of object-oriented relations between ancient artists and portable rock art instances from Kamyana Mohyla. Their complex role caused the dialectic kind of relationship between all the actors — the cultural landscape, humans and things — through these things themselves, and was included in technological contexts. Arguing that such instances should be studied in their existential complexity, we approach their understanding through the advances of contemporary philosophy.

### STYLE AND IDENTITY IN ROCK ART STUDIES

**Abstract author(s):** Ponomareva, Irina (Griffith University)

**Abstract format:** Oral

The paper discussed the relevance of the style concept in uncovering prehistoric ethno-cultural identities. Style in rock art studies was in focus of many debates, and researchers in various national archaeological traditions understood it differently. However, the most common and appropriate definition is that style is a manner of depiction of a subject. Notwithstanding its simple characterization, the interpretation of patterns revealed by stylistic analysis is not an easy task. In this paper, I present a case study on Siberian rock art which demonstrates how stylistic patterns can be explained in terms of negotiating and maintaining ethno-cultural identities. In this approach, rock art is understood as an active agent in structuring people's identities. Rock art sites create and maintain a strong connection between people, their past and their land. This means that rock art does not just reflect group or individual identities, but it helps construct them through powerful emotional attachments. Therefore, style changes may be a reaction to major social shifts or threat to cultural continuity, and in this condition, ethnic identity may emerge or strengthen.

### MOUNDS AND MONUMENTALITY IN BROADER PERSPECTIVES: DIGITAL AND NON-DIGITAL TECHNIQUES TO EXPLORE PAST BARROW LANDSCAPES

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Carrero-Pazos, Miguel (UCL Institute of Archaeology) - Rodríguez del Cueto, Fernando (University of Oviedo) - Szubski, Michał (Cardinal Stefan Wyszyński University in Warsaw)

**Format:** Regular session

Building from past EAA annual conferences (Barcelona 2018; Bern 2019; Virtual 2020), we present a follow-on session that aims to focus on the archaeological study of one of the most common archaeological remains in Europe, such as the barrow monuments are.

More than 30,000 mounds are still preserved across this territory, remnants of a much higher number which existed in the past. The mounds are, therefore, "ubiquitous" in the world, and this has led to common archaeological problems in the research of barrow landscapes. This session aims to share both historical and methodological problems jointly with solutions provided by digital and non-digital methods, and without any chronological restriction, from prehistoric to modern times. The main goal is to gather specialists from different periods and regions to discuss, through a variety of case studies and methods, the analysis of past barrow landscapes.

The session will accept proposals on the following topics:

- Data acquisition: proposals involving digital and non-digital techniques will show how to get accurate information as a basis for the development of good research practices. Approaches about the automatic detection of mounds will be

very welcome.

- Analysis and Interpretation: proposals involving traditional landscape archaeology and computationally focused research, with presentations on how geospatial techniques are fundamental to get new knowledge from those past social landscapes.

### ABSTRACTS:

1

### XIX-TH C. MAPS AND TOPOGRAPHIC DOCUMENTATION AS THE SOURCE OF EVIDENCE OF THE DESTROYED BURIAL MOUNDS (SUZDAL OPOLIE)

**Abstract author(s):** Erokhin, Sergey (Institute of Archaeology, Russian Academy of Sciences) - Krasnikova, Anna (State Historical Museum) - Makarov, Nikolai - Ugulava, Nani - Milovanov, Sergey (Institute of Archaeology, Russian Academy of Sciences)

**Abstract format:** Oral

The common modern methods of determining the burial mounds' location include predictive modeling and analysis of satellite images, which are sometimes not effective enough in the rural regions of Europe, where intensive centuries-old plowing totally leveled burial mounds. Potential of the XIX-th c. maps, including those, drawn for the archaeological field reports, in the context of present-day search for the burial sites is often underestimated.

More than 7700 mounds were excavated in 1851-1852 in the central region of Northern-Eastern Rus'. Field investigations were accompanied by instrumental topographic survey. 73 known maps can be divided in two groups in accordance with their scale and methods of creation:

1. maps of individual necropolis (scales 1:840 or 1:1680) and the location of the groups with reference to other objects (scales 1:21000 or 1:42000) as a result of instrumental or semi-instrumental survey
2. general maps, which present the location of burial sites on small scale maps of the region (scales 1:84000, 1:168000, 1:420000).

The location of known sites enables to estimate the potential and pitfalls of this source of information. The crucial aspects are documentation integrity, survival of reference objects in the survey area and maps inconsistency (in generalization from large to small scale). Georeferencing of maps, not affected by the last two problems, indicates that the positioning error is about 100 m for large scale map (Gnezdilovo, 1:21000) and about 200-300 m for small scale (Shekshovo, 1:84000). The geophysical scheme of Gnezdilovo burial mounds matches large scale (1:840) map, revealing its semi-instrumental nature and allowing to evaluate its credibility. Thus, there are cases when the analysis of the XIX-th century topographical documentation can make significant contribution to the search for the invisible mound sites and corresponding cartographic materials are worth georeferencing.

The work was supported by Russian Scientific Foundation grant №19-18-00538.

2

### REDISCOVERED MOUNDS IN NORTHERN JUTLAND, DENMARK - A CARTOGRAPHICAL SURVEY

**Abstract author(s):** Haue, Niels (Historical Museum of Northern Jutland)

**Abstract format:** Oral

In 1873 the chief curator of the National Museum J.J.A. Worsaae launched a systematic survey of prehistoric monuments in Denmark. This survey was only brought to an end in 1930 where all the ancient monuments in the country were considered recorded. The surveys included all ancient monuments and sites still visible as well as locations of lost monuments still known in local communities. In 1937 a new law for the protection of ancient monuments was approved. The key issue in this law was that all visible monuments now were protected by the law. Whether a monument was visible or not should be determined by the National Museum. In order to do so, all the monuments recorded in heritage archive had to be looked upon again. A task that took 20 years and with some adjustments during the last 80 years, the heritage archive now contains a total of 6.822 burial mounds in the survey area, where 2.970 was listed as protected monuments.

Following the agricultural reforms in the late 18th century large parts of Denmark were measured and mapped. These maps are known as the eldest cadastral maps and were drawn in a scale of 1:4.000 and therefore contain a great number of details, including much useful information for archaeologists: Place names, soil quality, burial mounds etc. These information's were unfortunately not included in the archaeological surveys during the 19th and 20th century.

This paper will present a study that combines a digitalization of these historical maps and the heritage archive. This offers a unique opportunity to re-evaluate the archaeological source material. In the survey area, an increase of mounds by 30% could be obtained. These numbers should furthermore be regarded as a minimum.

3

### MORTUARY HOUSE SEEN AS ANOMALY IN MAGNETOMETRY OF A DOUBLE-BARROW. CASE STUDY OF MIDDLE BRONZE AGE CEMETERY OF BUKIVNA (UKRAINE)

**Abstract author(s):** Romaniszyn, Jan - Niebieszczański, Jakub - Cwaliński, Mateusz (Faculty of Archaeology, Adam Mickiewicz University in Poznan) - Rud, Vitaliy (Institute of Archaeology, National Academy of Sciences of Ukraine in Kyiv) - -Radke, Iwona (Department of Quaternary Geology and Palaeogeography, Faculty of Geographical and Geological Sciences, Adam Mickiewicz University in Poznań) - Spychalski, Waldemar (Department of Soil Science and Land Protection, Faculty of Agronomy and Bioengineering, Poznań University of Life Science) - Jarosz, Paweł (Institute of Archaeology and Ethnology Polish Academy of Sciences in Kraków) - Bahyrycz, Cezary (Faculty of Archaeology, Adam Mickiewicz University in Poznan) - Staniuk, Robert (Institut für Ur- und Frühgeschichte, Christian-Albrechts-Universität in Kiel) - Makarowicz, Przemysław (Faculty of Archaeology, Adam Mickiewicz University in Poznan)

**Abstract format:** Oral

Following presentation is focused on the so-called double barrows of the Komarów culture (Middle Bronze Age) in Western Ukraine. Its aim is to demonstrate the potential of conducting magnetometry prospection and verification procedures (excavations, sedimentological and geochemical analysis and magnetic susceptibility testing) in order to identify the internal architecture of mounds. This particular case study is oriented towards the recognition of a double barrow in Bukivna, which included the so-called mortuary house made of wood and clay. The structure was burnt and it is clearly visible on the magnetometry imagery as a dipolar anomaly. This particular anomaly can be distinguished from the normal distribution of magnetization of a mound-like structure. Interpretation is supported by excavations and geoarchaeological testing of the samples. The contrary example comes from the Pidhoroddia cemetery, where a similar in shape, double mound was recorded, however with no indications of a mortuary house distinguishable in a magnetometry plan.

4

### LATE VIKING-AGE BURIAL SITES IN SUZDAL’ OPOLIE (CENTRAL RUSSIA): MULTIDISCIPLINARY RESEARCH AT GNEZDILOVO

**Abstract author(s):** Krasnikova, Anna (State Historical Museum) - Makarov, Nikolai (Institute of Archaeology, Russian Academy of Sciences) - Modin, Igor (Moscow State Universty) - Erokhin, Sergey - Schevchenko, Vladimir - Ugulava, Nani - Milovanov, Sergey (Institute of Archaeology, Russian Academy of Sciences)

**Abstract format:** Oral

Gnezdilovo is known as one of the first investigated Late Viking-Age burial sites in the large-scale excavation campaign of the 1851-1854 in Suzdal Opolie, focused on the barrow cemeteries. Since then, plowing completely destroyed all the barrows in Gnezdilovo, and until recent field work burial site was lost, despite the large excavations of the corresponding settlement in 1980-ies an intensive surveys in the local area.

Burial site was re-discovered in 2019, surveys included georeferencing of maps of the 1851 excavations, fieldwalking and metal detecting. Field research, conducted at the cemetery, was based on multidisciplinary approach, previously introduced at Shekshovo site. The borders and the structure of the cemetery were defined by means of geophysical investigations. Electric and magnetic survey enabled to map the individual burial mounds, necropolis borders, and zone of the necropolis with individual flat graves in the pits. Geophysics revealed about 30 barrow platforms, their arrangement and number match the survived XIXth century excavation scheme of burial mounds. Nevertheless, burial mounds distribution at the site requires further investigations: several dozen barrows seem to be too low number for the settlement with the nearly 15 ha area.

Although not all interpretation models from Shekshovo suited the data from Gnezdilovo, the approach showed its efficiency, making it possible to locate, map and investigate the burial mound site structure in short time frame.

The work was supported by Russian Scientific Foundation grant №19-18-00538.

### INTERPRETING ALS DATA OF HISTORICAL LANDSCAPE IN THE FOREST ZONE OF THE EUROPEAN PART OF RUSSIA. CAPABILITIES, ISSUES AND VISUALIZATION

**Abstract author(s):** Novikov, Vasily (The Russian Academy of Sciences Institute of Ethnology and Anthropology - IEA; Energotransproekt) - Kainov, Sergey (State Historical Museum, Russia) - Goriacheva-Dorodnix, Svetlana (Energotransproekt) - Goriachev, Ivan (Paleoethnology Research Center) - Sagmanova, Gulnaz (Kazan Federal University - KFU) - Dozorceva, Evgenia (Universita ha-lvrit bi-Yerushalayim - HUJI) - Kurilenko, Dmitriy (Energotransproekt) - Vlasov, Dmitry (Energotransproekt; Moscow State University - MSU)

**Abstract format:** Oral

ALS, photogrammetry and other 3D-digital collections methods do not provide us an explicit and completely interpretations of affected historical and barrow landscape especially in forest zone of the European part of Russia. Actually, during ALS survey we have a deal with combinations of single mound or barrow groups, which in general cases are differentiating features for historical landscape. Barrows organize the boundaries of archaeological sites and allow to translate ALS data into a meaningful plan for archaeologist.

The interpretation of barrow landscape in Russia built now on experience of collecting data from various sites (ALS is still new method for forested zone of Russia). Obviously, that necropolis contain different burial types such as cremation onsite and on the side, inhumation in burial chamber with or without mound etc. it is necessary to reckon with problems of interpreting of damaged, de-

stroyed ploughed up mounds, excavated and mounds, which were repaired after excavation. Moreover, in reality we need to analyse only mounds and ditch’s, which could give us explicit and full-scale information.

Verification ALS data are needed to use a complex of different non-invasive methods, which base on geophysical survey, reviewing of historical aerial images and satellite data and walking reconnaissance.

During 2018 – 2020 years projects of ALS archaeological objects, which included a barrow landscape, were investigated 16 sites in forested zone of Russia (2511 he). For understanding methods of ALS part of sites with barrow landscape were investigated twice with different altitude and speed. The combination with different non-invasive methods are allowed common principles of understanding historical landscape with different type of burials. For destroyed barrow landscape were used 3D-modelling, landscape reconstruction and immersive AR-visualisation.

6

### ACCESSING THE PREHISTORIC TELLS IN THE BALKANS

**Abstract author(s):** Naumov, Goce (Center for Prehistoric Research / Goce Delčev University)

**Abstract format:** Oral

Tells were a phenomenon of settlements associated with the introduction of the first farming communities in the Balkans, but also were maintained as residual areas further in prehistory. For a century they are studied with a variety of methods during surveys and excavations and therefore significant data was provided regarding their disposition, spatial organization, site formation processes, chronology and about communities that inhabited them. Although quite a recent practice in its initial developing phase a series of digital methods were applied in order to detect the tells in the landscape and consequently to study the relationship between these mounds and their environment. Furthermore the advanced techniques were employed as well in order to study the disposal of architectonic features and consequently to provide a habitat reconstruction. This presentation will particularly elaborate current research on tells in Pelagonia and emphasize the multidisciplinary approach that enables better understanding of these settlements, their distribution and surrounding, as well as the processes manifested on the site formation and continual residence in particular spots inside them.

### REDEFINING PAST MOUNDSLAPES IN THE ROMAN-PERIOD GREAT HUNGARIAN PLAIN

**Abstract author(s):** Masek, Zsófia (Institute of Archaeology, Research Centre for the Humanities, Budapest)

**Abstract format:** Oral

The remaining mounds of the Great Hungarian Plain have been protected by the law in Hungary for decades, thus preserving the remains of the originous steppe-grasslands as the westernmost biological refugiums of the Eurasian steppe. However, the landscape has been and is widely cultivated, therefore a significant part of the mounds are already completely destroyed or are under constant threat. The presentation deals partly with vanished mounds, and also with well-preserved memorials. Problems of archaeological research may also be due in a measure to these different conditions.

Roman-period barrow graves or kurgans have been reckoned in this region since the mid-19th century. However, research into prehistoric objects has become much more advanced. Study of Roman-period Sarmatian monuments alienated from the interpretation of excavated objects, which were assessed as burials surrounded by ditches. Non-destructive research in recent years has confirmed that we need to interpret memories of different preservation, grave markings and sizes (ca. 5-50 m) in a common system.

The contribution concerns the re-discovering of long-known, lost sites with the use of various datasets, and their confirmation with non-destructive survey. Due to the general encirclement of the barrow graves, it is necessary to study the subsurface phenomena parallel to the micro-relief investigations; besides, morphology of grave markings could advance chronological classifications. The issues raised would be presented through case studies.

Some of the survived grave mounds are mementos of complex Roman-period mounslapes. Based on surveyed cemetery structures, some different reconstructions of social landscapes are to be mentioned. The re-use of the mounds in various respects is continuous to the modern ages. However, special attention is given to the sites, which were used as burial places of early medieval ethnic groups in the following centuries (5th-10th c.), which shows the long-term mental impact of these landscapes.

8

### THE VISIBILITY AS A LOCATIONAL FACTOR IN THE MEGALITHS OF SOUTHERN GALICIA

**Abstract author(s):** Carrero-Pazos, Miguel (UCL Institute of Archaeology)

**Abstract format:** Oral

The analysis of the visual role of ancient monuments has a long tradition in Archaeology, being one of the most important applications of GIS methods in the current archaeological science. This work focuses on the study of the visibility as a locational factor in the megaliths of Monte Penide and Galiñeiro using GIS and spatial statistics methods. The research aims to analyse if it was the view from the mounds, the view to them, or possibly a joint explanation among both factors, the element which determined the spatial value of the megalithic structures, something that was inspected only up-do-date by fieldwork approaches in the selected region.

The research is structured in four methodological parts. First, we start from the analysis of the landscape where the megaliths were built through the reconstruction of the visual landscapes (visualscapes). Secondly, a study of the view from the monument is carried out through the analysis of the size of their viewsheds, using Monte Carlo simulation as significance testing. The aim is to check if the size of the visual basin of the megaliths converges (or diverges) with the surrounding landscape. Third, the view to the mon-

uments was approached through a combined study of the natural transit network and the visibility of the mounds. As a final step, we studied the particular skyline of the monuments, which allowed us to complement these approaches with more spatial values. The results point out the complexity of this variable, probably crucial when selecting the specific locations where to build the megaliths. We defend the idea that the homogeneous visual presence of the funerary structures could have been one of the elements that marked the creation of the spatial structures in the Neolithic communities, that is, their territories.

9 ROCKS AND KINSHIP: RECONSTRUCTING THE FUNERARY LANDSCAPE OF EASTERN SUDAN

**Abstract author(s):** Costanzo, Stefano (Dipartimento Asia, Africa e Mediterraneo, Università degli Studi di Napoli “L’Orientale”) - Brandolini, Filippo (McCord Centre for Landscape - School of History, Classics and Archaeology, Newcastle University) - Ahmed, Habab (NCAM - National Corporation for Antiquities and Museums, Khartoum) - Zerboni, Andrea (Dipartimento di Scienze della Terra ‘A. Desio’, Università degli Studi di Milano) - Manzo, Andrea (Dipartimento Asia, Africa e Mediterraneo, Università degli Studi di Napoli “L’Orientale”)

**Abstract format:** Oral

The funerary landscape of the Kassala region (Eastern Sudan) is a complex palimpsest of raised monuments belonging to different time periods. Such monuments add up to several thousands of elements and are divided in two main categories: early to late 1st mill CE round stone mounds (tumuli) and medieval Islamic square shrines (qubbas). Despite their huge number, local mounds and shrines remained largely unknown to the international archaeological community until today, mostly due to their geographic and cultural isolation. With this talk, we present the results of a cross-disciplinary study that employs geoarchaeological fieldwork and desk-based digital techniques. A description of the landscape-scale spatial distribution of qubbas was achieved by performing geospatial analysis on a large desk-based dataset of monuments over a geomorphological regional basemap. The interpretation of local-scale aggregations of qubbas was achieved by furthering the analysis to define the occurrence of elusive social dynamics. Our results strongly suggest the presence of a geological/environmental/societal synthesis underlying the choice of monuments’ location. At the regional scale, their distribution follows a precise set of rules residing in the concomitant presence of stable, gently rolling slopes and readily available raw stone material; at the local scale, the clustering is conditioned by the presence of older tumuli and by superstructural dynamics that most likely reside in kinship and collective social memory of the local Beja people. The Bejas are a conservative society of semi-nomadic cattle breeders known to have inhabited the region since “time immemorial”. Our results suggest that for more than two millennia they seem to have fit their funerary monuments to shifting religious beliefs, yet retaining continuity between tumuli and qubbas through a well coded social behaviour that valued location and kinship over external influences.

10 HERE IS THE BARROW AND WHAT NEXT ...

**Abstract author(s):** Wawrzeniuk, Joanna (Institute of Archaeology, Cardinal Stefan Wyszyński University in Warsaw)

**Abstract format:** Oral

How little we know about the cultural heritage hidden in the forests, many researchers has already alarmed and described. However, thanks to new methods, including Airborne Laser Scanning, and using LIDAR visualization, different features previously unknown from surface prospecting can be discovered and researched. However, even the excavation can often bring more questions than answers. An example are the results of field work on a mound on a newly recognized barrow cemetery located in the Ładzka Forest (part of the Białowieża Forest). Wooden construction in the embankment, cremation burial in a vessel, sacrificial pits with stones, burnt bones and wood’s pieces. The fragments of pottery from different period were discovered. Some of them are connected with the settlement located under and next to the mounds. The remains of ancient fields are also related with them.

The research was carried out as part of a project financed by the National Science Center entitled: Cultural and natural heritage of the Białowieża Forest, at the Cardinal Stefan Wyszyński University in Warsaw.

11 MOUNDSCAPES OF THE BIELSKA PLAIN – SUMMARY ATTEMPT

**Abstract author(s):** Szubski, Michal (Cardinal Stefan Wyszyński University in Warsaw)

**Abstract format:** Oral

The Bielska Plain is the major region located in north-east Poland. Because of one of the oldest forests in Europe, the Białowieża Primeval Forest, located here it is perfect example of anthropogenic impact on prehistoric landscape. One can compare how archaeological landscape preserves in highly protected area and how it was destroyed by modern ploughing and urbanization at rest of the region.

With archival query and usage of LiDAR technology more than 2000 mounds with anthropogenic relief from different chronological periods has been found – among them barrows, tar kilns, charcoal kilns and more. After remote sensing and verification of the region features, next step was to prepare several DTM derivative models to try understand environment and geospatial regularity for mound sites. Also several spatial analysis were conducted for clusters. That allow to investigate this unique moundscape in entirety shape.

After four years of research the paper will try to summary current state of knowledge and application of spatial methods used to investigate mounds of the Bielska Plain.

365 “INVISIBLE PRODUCTS”- SCIENTIFIC ADVANCEMENTS IN IDENTIFYING ANIMAL SECONDARY PRODUCTS AND THEIR CONTRIBUTION TO UNDERSTANDING ANIMAL DOMESTICATION AND HUMAN-ANIMAL RELATIONSHIPS

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Gur-Arieh, Shira (Institute for Prehistoric and Protohistoric Archeology and Provincial Roman Archeology, Ludwig-Maximilians-University, Munich; CaSEs Research Group - Culture and Socio-Ecological Dynamics, Department of Humanities - Universitat Pompeu Fabra) - Madella, Marco (CaSEs Research Group - Culture and Socio-Ecological Dynamics, Department of Humanities - Universitat Pompeu Fabra, Barcelona) - Spiteri, Cynthianne (Institute for Prehistory, Early History and Medieval Archeology, Eberhard Karls University Tübingen)

**Format:** Regular session

While the identification of meat exploitation in antiquity is relatively straight forward through the study of animal bones, identifying the use of animal secondary products, meaning, products that can be continually harvested during the animals’ life without slaughtering it (e.g. milk, wool, dung, eggs, honey, etc.) often requires the use of multi-disciplinary scientific methods. From the study of milk products using microbiology, lipid residues and proteomics to the identification of animal dung exploitation using micromorphology, these kinds of studies not only reveal otherwise almost invisible animal products, but they also provide a better understanding of human subsistence practices and human-animal-environmental relationships. In the last two decades, the adoption of methods from the natural sciences to archaeology has allowed some tremendous advances in the identification of animal secondary products, pushing back in time their utilization by humans and highlighting their importance as a motivation for animal domestication. In this session, we aim to review the latest scientific advancements and discoveries, and importantly, discuss future directions in the study of animal secondary products and how these contribute to our understanding of the socio-economic implications brought about by human-animal interactions.

ABSTRACTS:

1 RETHINKING THE ROLE OF ANIMAL DUNG AS A PIVOTAL ELEMENT IN HUMAN ADAPTATION TO A SEDENTARY LIFESTYLE

**Abstract author(s):** Gur-Arieh, Shira (Ludwig-Maximilians-Universität München; CaSEs, Department of Humanities, Universitat Pompeu Fabra) - Madella, Marco (ICREA - CaSEs, Department of Humanities, Universitat Pompeu Fabra. Barcelona)

**Abstract format:** Oral

In studies targeting the Neolithic revolution and the transition from a hunter-gatherer lifestyle to a sedentary one, plant and animal domestication, hence the shift to food production, are the key research foci. Animal dung, on the other hand, is still considered as a secondary by-product to animal domestication, even though the last years have seen a growing body of evidence showing that humans may have recognized its properties, and at times used it prior to, or alongside the process of animal domestication. In this talk we would like to review the role of dung in human adaptation to harsh environments, as it unfolds from historical, ethnographic, and archaeological sources, to suggest a multi-proxy workflow for dung identification, both as a fast-screening method in a field laboratory, and as detailed studies as part of post-excavation analysis processing. The use of animal dung as a proxy for human-animal interactions will be discussed, and future direction in this field of studies suggested.

2 HUMANS AND ANIMALS IN CLOSE PROXIMITY – A STUDY OF THE DUNG FROM AENEOLITHIC MONJUKLI DEPE IN SOUTHERN TURKMENISTAN

**Abstract author(s):** Ögüt, Birgül (German Archaeological Institute, Oriental Department, Berlin/Germany) - Cereda, Susanna (Universität Innsbruck, Institut für Archäologien, Mikroarchäologisches Labor, Innsbruck/Austria)

**Abstract format:** Oral

Monjukli Depe, a small prehistoric village in southern Turkmenistan, was inhabited in the Late Neolithic (ca. 6200-5600 BCE) and again in the Early Aeneolithic (ca. 4800-4350 BCE). Analyses of the animal bones demonstrate that sheep, goats, and cattle were all reared and herded by the villagers. Dogs are also attested at the site, by the occurrence of pawprints inside some of the Aeneolithic houses.

In this paper we present the results of new studies that have focused on analysing sedimentary deposits taken from open spaces, uninhabited ruins, and inhabited houses. The integration of phytolith and dung spherulite analyses, together with micromorphology examination demonstrated that the spatial proximity of herd animals and people was much closer than previously assumed, raising new questions about the places where animals were kept or had access to. Furthermore, the new data has prompted a rethinking of human-animal relationships; not only in terms of seasonality, care, husbandry and the exploitation of secondary products, but also of the perceptual and emotional dimension associated with spatial proximity to animals, such as warmth, hapticity, companionship, etc.

3 “ALL WOOL AND NO SHODDY”, AN INTER-DISCIPLINARY STUDY OF CLOTH PRODUCTION AT IRON AGE TELL ES-SAFI/GATH

**Abstract author(s):** Cassuto, Deborah (Bar Ilan University; Albright Institute of Archaeological Research) - Kolska Horwitz, Liora (Hebrew University) - Maeir, Aren (Bar Ilan University)

**Abstract format:** Oral

Remains of woven cloth are rare in archaeological sites in the Near East, such that we have little idea as to the raw materials exploited for their production i.e., plant fiber versus animal fiber, or the extent of fabric production that took place in different periods and sites. Consequently, we need to turn to alternative sources of information in order to assess these issues.

The site of Tell es-Safi/Gath, located at the interface between the coastal plain (Philistia) and the Judean Foothills (the Shephelah) in Israel, offers an excellent case study with which to explore this issue, since it has yielded a rich corpus of well-preserved material culture, as well as organic remains, spanning, in addition to earlier periods, the Late Bronze Age, Iron Age I and II (ca. 1500-700 BCE).

In this presentation, we examine the presence and quantity of finds from this site that may elucidate the nature and extent of cloth production carried out on-site. This includes data and various analyses on: architectural installations and tools that traditionally have been associated with textile production - such as stone vats, loom weights, spindle whorls and bone spatulas; the frequency of sheep and goats that may attest to wool production or hair exploitation as well as breed type – and evidence on grazing practices and herd proveniences (based on isotopes). Integration of these data-sets provides valuable information concerning fabric production at this site over a range of periods, and fills a hiatus in our knowledge. Our focus will be on the 9th century BCE material as it contains an impressively large corpus of loom weights (c.600) from diverse contexts, suggesting large-scale production of textiles on-site.

4 THE FIRST EVIDENCE OF WOOL FROM EARLY BRONZE AGE GRAVES IN POLAND (C. 2000 BC)

**Abstract author(s):** Kurawska, Aldona (Institute of Archaeology and Ethnology Polish Academy of Sciences) - Mrozek-Wysocka, Małgorzata (Institute of Geology Adam Mickiewicz University) - Hychała, Anna (Regional Museum in Hrubieszów) - Sobkowiak-Tabaka, Iwona (Faculty of Archaeology Adam Mickiewicz University) - Włodarczak, Piotr (Institute of Archaeology and Ethnology Polish Academy of Sciences)

**Abstract format:** Oral

Complex studies and multidisciplinary analyses of shell ornaments found in the Neolithic and Early Bronze Age burials in Poland surprisingly provided direct evidence for the use of sheep wool 2000-1600 BC. Residues discovered on the shell's surface were subsequently identified by using reflected light microscopy and scanning electron microscopy with energy dispersive spectroscopy (SEM-EDS). Sheep fibres were preserved on shells in mineralized form and identified on ornaments from at least six archaeological sites, dated to the Early Bronze Age. The fibres discovered on the surface of shell pendants were identified as remnants of textiles or sheepskin and as threads/strings inside the beads. The analysis indicated the presence of various fibres (kemp, coarse fibres, and fine fibres) typical for primitive sheep. Despite the possible exploitation of sheep for wool in the Late Neolithic period, indirectly indicated by animal remains, spindle whorls, and spools, on the territory of Central Europe wool fibres have not been identified so far. Among the analyzed shell ornaments from the Neolithic context, only remains of plant fibres were discovered.

The analyzed items are the first direct evidence of wool processing in the Early Bronze Age in Poland. Moreover, it was noticed for the first time that ornaments made of shells, in the specific context of inhumation burials, constitute calcium matrices on which mineralized forms of organic materials are preserved. Our research provides important information for understanding the early textiles economy. The potential and significance of the finds, in the study of sheep exploitation for wool, should be further explored.

5 (IN)VISIBLE WOOL IN IN THE PREHISTORIC AEGEAN TEXTILE PRODUCTION

**Abstract author(s):** Siennicka, Malgorzata (University of Göttingen, Institute of Archaeology)

**Abstract format:** Oral

Organic materials, e.g. textiles, are hardly ever preserved in the prehistoric Aegean (c. 3000-1200 BCE). Especially from the Early and Middle Bronze Age there are virtually no archaeological remains of woolen or vegetal fibres and fabrics, while from the Late Bronze Age contexts several mineralised textiles came to light. Whereas both vegetal fibres, and animal products, like skins, furs, and hairy wool had been exploited for thousands of years for making clothes, and other household fabrics, the woolly wool, also known as long-staple wool, appeared in the Aegean probably only in the 3rd millennium BCE. Its long fibres could be spun with hand spindles, and then woven on looms. The new textiles had different properties than those based on plant fibres: they were warm, soft, water-repellent, and they could be dyed in a range of colours and hues, which made them look more remarkable. Textiles and textile production have gained a new social and economic significance, as the Late Bronze Age written sources demonstrate. Nevertheless, the spread of the woolly wool in the Aegean must have been a long process. Because of lack of archaeological remains of wool from the EBA and MBA, that could be scientifically analysed, a careful study of textile tools can possibly shed light on the introduction and spread of this innovation. As we know that wool requires different types of spinning tools than those used to prepare plant fibres, it is possible to study potential modifications of spinning tools in order to indirectly trace the use of wool. Specifically, masses and diameters, as well as the shapes of the spindle whorls made of clay, stone and bone, could be informative in that matter. This paper offers an alternative method of studying the use of wool in textile production without scientific analyses of wool remains.

6 “BAA, BAA BLACK SHEEP, HAVE YOU ANY WOOL?” WOOL TRADE NETWORKS EVALUATED THROUGH STRONTIUM ISOTOPE ANALYSES AT BORGUND KAUPANG, NORWAY

**Abstract author(s):** Smith, Michele Hayeur (Haffenreffer Museum of Anthropology, Brown University) - Dahle, Kristoffer (Møre og Romsdal fylkeskommune)

**Abstract format:** Oral

The town of Borgund Kaupang, on Norway's western coast, was founded in the late Viking Period and flourished during the Middle Ages. As a regional commercial center, it occupied a poorly studied position linking smaller hinterland communities to coastal networks that linked ports such as Bergen and Trondheim with the North Atlantic Islands and continental Europe. A large, international project organized by the University of Bergen is currently reviewing and revitalizing legacy collections from excavations of the 1950s-1970s at Borgund Kaupang. Textiles are surprisingly well-preserved in its excavated contexts and provide one avenue for examining the roles of local versus imported products in trade and the life of the town. Initial strontium isotope analyses suggest that most of these are of Norwegian origin, rather than imports from the North Atlantic islands or other parts of Europe. This differs from the situation in Bergen and Trondheim, where imports seem to have been more significant. Yet, if this pattern appears strong at Borgund Kaupang, questions remain about whether the woolen textiles found there were produced exclusively in its local hinterland or came from other parts of Norway through internal trade routes competing with or linked to the networks connecting Norway's main ports. Comparative samples of modern wool are helping us to establish strontium baselines for wool from different parts of Norway and will be compared to Borgund Kaupang's archaeological samples. Already, evidence for local production of woolsens from the earliest phases of the site raises questions about whether Borgund Kaupang produced specialized cloth for exchange or was a node within internal or local trade networks. Were these textiles produced in Borgund for trade with its periphery or were they produced elsewhere in the periphery to supply early urban centers such as this one?

7 REINDEER AS TRACTION: NEW METHODS FOR IDENTIFICATION OF WORKING REINDEER AND ARCHAEOLOGICAL EVIDENCE FROM NORTHEASTERN FENNOSCANDIA

**Abstract author(s):** Salmi, Anna-Kaisa - van den Berg, Mathilde - Niinimäki, Sirpa - Pelletier, Maxime (University of Oulu)

**Abstract format:** Oral

The domestication of the reindeer among the Sámi of Northern Fennoscandia is one of the pressing questions in the archaeology of the area. Although the importance of draught reindeer in early reindeer domestication has been hypothesized, direct archaeological evidence on the matter has been lacking. In recent years, new methodological possibilities, such as analysis of palaeopathological lesions, bone cross-sectional properties, entheses changes and geometric morphometrics have become available for the identification of reindeer physical activity patterns such as draught use on faunal remains. In this paper, we present some of the new methodological tools available for reindeer physical activity reconstruction. Moreover, we discuss the first archaeological application of these methods to faunal remains from Sámi dwelling sites in Northeastern Fennoscandia.

We present the analysis of palaeopathological lesions and entheses changes in the faunal assemblages from three Sámi dwelling sites in Northeastern Fennoscandia, dated between ca. 1300-1800 AD. The results suggest that working reindeer were present in the archaeological assemblages likely from 1300 AD onwards. This is the earliest direct evidence of draught reindeer use by the Sámi. It predates the earliest unequivocal historical sources on draught reindeer use dating to the 16th century and confirms the hypothesis that draught reindeer played an important role in early reindeer herding. It also shows that that small-scale reindeer herding was integrated into the subsistence strategy of the Sámi of Northeastern Fennoscandia earlier than previously suggested.

8 RAISING AWARENESS OF THE INVISIBLE: POLYVALENT EXPLOITATION OF THE FIRST CATTLE HERDS IN EARLY NEOLITHIC IN NE IBERIA

**Abstract author(s):** Miralda, Joaquim - Sierra Sainz-Aja, Alejandro (Archaeozoology laboratory, GRAMPO, Department of Prehistory, Autonomous University of Barcelona) - Tarifa-Mateo, Nàdia (Institut de Chimie de Strasbourg UMR 7177, CNRS, Université de Strasbourg) - Alcàntara Fors, Roger (Archaeozoology laboratory, GRAMPO, Department of Prehistory Autonomous University of Barcelona; Pre-EINA Estudis Interdisciplinaris i Noves Aplicacions en Prehistòria, Jaume I University) - Saña Seguí, Maria (Archaeozoology laboratory, GRAMPO, Department of Prehistory, Autonomous University of Barcelona)

**Abstract format:** Oral

Knowing which animal products were used in the past is a fundamental question to study the initial animal husbandry practices. However, these products can be often dismissed in archaeological analyses due to their perishable nature. Since a lot of these products or resources become disintegrated, we must find new ways to identify markers of these ancient resources.

In the last decades, many new techniques have been applied to the study of consumption patterns and animal production in the past. The use of organic residue analysis (ORA) to identify the so-called “secondary products” is already common in archaeology. Other methodologies are also continuously being implemented to study animal life conditions and husbandry practices they were involved in. In this communication, we aim to correlate different analyses in an integrated study that can trace back the use of cattle in the Early Neolithic in La Draga settlement.

The study brings together ORA, mortality profiles, biomechanical adaptation, bone microstructure analyses and paleopathology analyses. Taking the cattle mortality profiles as a base reference we will evaluate the potential uses of cattle by bringing together

the evidence of milk exploitation and consumption brought by ORA and the study of osteon conformation. The evidence on cattle loading patterns brought by the biomechanical analysis, the palaeopathological study of cattle remains and the osteon conformation as signs of the management strategies and alternative uses implemented.

Dairy products were detected in four pots from La Draga by ORA supporting milk consumption. Age at death pattern analysis show milk slaughter pattern inclination for cattle as well as osteon conformation supports this hypothesis for specific individuals. Besides, cattle first phalanges biomechanics analysis and osteon examination show a significant amount of stress related to the loading and animal draught exploitation.

9

SECONDARY ANIMAL PRODUCTS IN AFRICAN SOCIETIES. A CASE STUDY FROM THE EARLY IRON AGE SITE OF LYDENBURG HEADS, SOUTH AFRICA

**Abstract author(s):** Becher, Julia (University of Tuebingen) - Schoeman, Alex (University of the Witwatersrand) - Buckley, Stephen (University of York; University of Tuebingen) - Whitelaw, Gavin (KwaZulu-Natal Museum) - Celliers, Jean-Pierre (Lydenburg Museum) - Spiteri, Cynthianne (University of Tuebingen)

**Abstract format:** Oral

In the last two millennia people in southern Africa relied on secondary products of domestic stock. While milk products were commonly a staple, domestic stock was mainly slaughtered in ceremonial occasions. Due to high percentage of lactose intolerance within these societies, secondary milk products, such as sour milk, curds and whey, or butter, were generally used instead of fresh milk. People further consumed processed crops, gathered plants and fruits, and supplemented their diet with hunted and snared game. However, there is little direct evidence for the dietary practices during the Early Iron Age (AD 200-900; EIA) in South Africa. In order to investigate subsistence patterns and vessel use through time, organic residue analysis (ORA) was applied to ceramics from the site of Lydenburg Heads, South Africa. The initial seventh century AD occupation of the site was associated with Mzonjani facies pottery, and the ninth to eleventh centuries AD reoccupation contained Doornkop facies pottery. For this study, 40 sherds were sampled (Mzonjani occupation, n=20; Doornkop occupation, n=20). This represents the first ORA study ever conducted in this area and in this archaeological context. Here, we report on the processing of milk through the application of compound-specific isotope analysis (GC-c-IRMS), as well as the detection of coprostanol using a lipid biomarker approach (GC-MS), which implies the application of dung to ceramic vessels. Both findings represent the earliest evidence of its kind within early farming communities in southern Africa.

10

EXPLORATORY ORGANIC RESIDUE ANALYSIS FROM A 4000 BP MULTIPERIOD HABITATION SITE IN THE ZÜÜNKHANGAI REGION (MONGOLIA)

**Abstract author(s):** Davara, Javier - Égüez, Natalia (AMBI Lab, Instituto Universitario de Bio-Orgánica Antonio González, Universidad de La Laguna) - Seitsonen, Oula (University of Oulu) - Broderick, Lee (Oxford Archaeology) - Bayarshaikhan, Jamsranjav (National Museum of Mongolia) - Houle, Jean-Luc (Western Kentucky University)

**Abstract format:** Oral

This paper presents the preliminary results of organic residue analysis from a small set of pottery fragments that were recovered in 2018 in the context of the Western Mongolia Archaeology Project. Excavation of a present-day nomadic winter campsite produced a well deeply stratified profile of 1.60m depth. Radiocarbon dates from the profile cover a continuous and consistent occupation of the site for the last four millennia. The presence of large quantities of animal bones, primarily from sheep/goat, that also exhibited butchery marks associated with primary and secondary butchery, suggest that these two categories of primary domesticates played a major role in the Mongolian herders diet. Pottery fragment samples from several layers were analysed using gas chromatography/mass spectrometry (GC/MS) combined with single compound stable isotope ( $\delta^{13}\text{C}$ ) analysis (GC-c-IRMS), to explore diet and ultimately shed new light into food choices and provisioning of the people that occupied the site since the Early/Middle Bronze Age (c. 2000-1700 cal. BC). Analytical methods, interpretative strategies, and anthropological implications will be discussed.

A.

THE USE OF DUNG AS FUEL: MICROMORPHOLOGICAL ANALYSIS OF THE ES-1610 STRUCTURE OF THE FORTRESS OF ELS VILARS (ARBECA, SPAIN)

**Abstract author(s):** Carbonell-Roca, Joan - Bergadà, M. Mercè (SERP. Departament d'Història i Arqueologia, Universitat de Barcelona) - Alonso Martínez, Natàlia (GIP, 3DPatrimoni, Departament d'Història, Fac. de Lletres, INDEST, Universitat de Lleida)

**Abstract format:** Poster

This work shows the results of a microstratigraphic study about combustions, carried out inside a structure located at La Fortalesa dels Vilars d'Arbeca (Arbeca, Lleida, Spain). Dating from the late 6th century BC, the structure is almond-shaped and is 5 m long and 1.20 cm wide. Located outside the walls, the structure was functioning underground, being buried about 50cm deep, and a drain was attached to its southern end. Without parallels in the Iberian world, its excavation showed a stratigraphy, formed by sedimentary levels and ash levels's layering.

The results of the micromorphological analysis have allowed to characterize the stratigraphic sequence, where the association of ash levels -formed mainly by prismatic calcitic pseudomorphs and some charcoals- and sedimentary levels with traces of thermoalteration stands out. However, we also find excremental aggregates with a high content of faecal calcium spherulites, disarticulated siliceous phytoliths and authigenic phosphate nodules.

All features suggest that combustions took place in situ and that herbivorous excrement were used as fuel. In fact, some other levels outside the settlement -not contemporaneous- have also shown the burning of dung. The use of this type of fuel has been widely discussed in other protohistoric contexts such as the Maghreb and in the Middle East but is not so usual, according to available data, in the Iberian Peninsula. Thus, micromorphology has been shown to be a highly effective tool in the analysis of such contexts, allowing the correct characterization of combustions, especially to identify the primary or secondary deposition of their remains and the fuel sources used.

IDEOLOGICAL, TECHNOLOGICAL & ECONOMIC CHANGE IN THE FIRST MILLENNIUM BCE AT THE EURASIAN EXTREMITIES: JAPAN AND BRITAIN IN WIDER CONTEXT

**Theme:** 4. Globalisation and archaeology

**Organisers:** Hutcheson, Andrew (Sainsbury Institute for the Study of Japanese Arts and Culture; University of East Anglia) - Mizoguchi, Koji (University of Kyushu) - Matsugi, Takehiko (The National Museum of Japanese History) - Hudson, Mark (Max Planck Institute for the Science of Human History) - Kaner, Simon (Sainsbury Institute for the Study of Japanese Arts and Culture; University of East Anglia)

**Format:** Regular session

In European archaeology the Bronze Age has been argued to represent an expanding world of proto-globalisation. The following Iron Age, by contrast has been interpreted in terms of more localised societies based around growing state power. However, the transitional period between Bronze and Iron saw new 'global' ideas spread across Eurasia. Although not generally discussed by archaeologists, the term 'Axial Age' has sparked historical, sociological, anthropological and popular interest since it was proposed by the German existentialist philosopher Karl Jaspers in his 1949 book The Origin and Goal of History. His Axial Age thesis proposed that between 800BCE and 200BCE religious, philosophical and societal innovations took place across the core of Eurasia. Figures such as Confucius, the Buddha, Zarathustra, Elijah, Homer, and Plato all belonged to this period. Recently the anthropologist David Graeber, in his book Debt: The first 5000 Years, argued there was a material basis to these new ideas in the First Millennium BCE, pointing particularly to the development of coinage in Greece, India and China around 600BCE. This session will examine whether the ripples from these changes can be seen across the Eurasian continent. Britain and Japan, at the extremities, saw social and material changes linked to the flow of ideas and material from the continent during the Iron Age and the Yayoi period. Increasing complexity, demographic changes and technological innovations took place. Agriculture based on rice, millet, wheat and barley appeared in Japan with new groups of people and metals. New metallurgical technologies, styles of artefact and coinage made their way into Britain at around the same time. Papers in this session will explore these themes and consider whether such large-scale historical narratives fit with archaeological investigation.

ABSTRACTS:

1

INTERPRETING AXIAL AGES

**Abstract author(s):** Andersen, Anna-Theres (Institute for Prehistoric and Historic Archaeology, Kiel University) - Nakoinz, Oliver (Johanna Mestorf Academy, Kiel University)

**Abstract format:** Oral

The axial ages concept, rooting in observations of the 19th century and developed by Karl Jaspers in 1949 gained new attention in recent years (Bellah/Joas 2012; Assmann 2018; Mullins et al. 2018; Peet 2019). On the one hand, it seems accepted that Jaspers original axial ages have some flaws including chronological issues but on the other hand, this theory is still very stimulating and open for a manifold of interpretations and applications which do not follow the canonical form. Following Assmann, we understand the axial age concept rather as a kind of heuristic than a sound theory of history. This paper is intended to offer some thoughts on different interpretations of the axial age concept. We do not discuss empirical evidence for the axial ages and we do not define the content of the axial age transformation but we aim to address a selection of interpretations that offer a specific perspective on the remarkable transitions observable in the First Millennium BC.

This paper starts with a short characterisation of the classical concept of Jasper and continues with some more recent interpretations from Peet (2019), and Assmann (2018). Furthermore, we address the reward system approach from Baumgard/Boyer/Hya-fil(2015) and the multiaxiality approach from Shults (et al. 2018) and Baskin (2019). In addition, we discuss the usage of the axial ages approach as a heuristic and simple temporal development model as well as a complex system approach. Which interpretation is the right one? How are they related? In which way do they guide future research?

2

CIVILIZATION AND BARBARIANS AT EITHER ENDS

**Abstract author(s):** Kim, Jinoh (Seoul National University)

**Abstract format:** Oral

In this presentation, I'd like to compare the situation of Korean Peninsula and Japan during the late periods of the First Millennium BC with those of Britain and Western Europe.

During the periods these regions began to make frequent contacts with the Chinese civilization and the Mediterranean World respectively. The civilizations imparted new technologies and cultural objects to the societies of those regions while they left some texts about their contacts with the so called barbarians. The contacts not only affected the ancient societies themselves but also the ways in which today's archaeologists investigate such societies, as the historical texts let us know their names and stories.

The historical texts and the archaeological data suggest that there were military campaigns, colonization and trades in both regions. And I'd like to point out that the contacts with the civilization might have contributed to the prestige and authorities of the local rulers. However, this trend seems to have been more salient at the East End because unlike the Chinese Empires who maintained the tribute system with the barbarians, the Romans conquered and annexed the Gauls and the Britons as provinces in the end.

3 THE BEGINNING OF SYMBOLISM

**Abstract author(s):** Barrett, John C. (University of Sheffield)  
**Abstract format:** Oral

That material culture is 'symbolic' is something that is widely accepted, whether or not archaeology is able to deal with this aspect of past material worlds. To say that material culture is symbolic is taken here to mean that things can act as a sign for (stand in place of) something else and that the thing therefore requires interpretation. Symbolism is therefore contentious in that we can argue about what things might mean. This paper will argue that symbolism is a relatively late and a marginal development in humanity's treatment of things. In place of the symbolic role of things it will be argued that things are more generally treated by humans as the manifestation of essential qualities. Thus, for example, sacred objects are sacred, in the way that the sacraments at a mass are transformed into the flesh and blood of Christ for some, while it is protestants and non-believers who would treat the bread and wine as being symbolic. From this perspective I will argue that prehistoric communities, and indeed many today, live in worlds that were and are made up of essential qualities manifest in things and not symbols. Consequently, the beginning of symbolism must mark a significant dislocation in the traditional understandings of the world. It is from this perspective that we might begin to understand the origins of philosophies that seek to interpret existence by claiming to know what things really mean (aka The Axial Age), the origins of writing where texts stand for words, and where coinage stands for values. I therefore doubt that these worlds of symbolic things ever permeated the European worlds of prehistory.

4 DRIVERS OF CHANGE: UNPACKING THE CAUSAL FORCE BEHIND CHANGES IN PRODUCTIVITY, WARFARE, INSTITUTIONS, AND IDEOLOGY ACROSS EURASIA WITH SESHAT DATABANK

**Abstract author(s):** Hoyer, Daniel (Seshat: Global history Databank; Evolution Institute; George Brown College) - Reddish, Jenny (Seshat: Global history Databank; Complexity Science Hub, Vienna)  
**Abstract format:** Oral

The Axial Age concept has had wide influence in historical, sociological, and archaeological narratives since its early articulation in the late 19th century. Since then, a wealth of historical and material evidence has been marshaled to defend and refine the concept, however, no clear picture of what exactly this Age was and how it came to be has emerged. Seshat: Global History Databank provides new tools for examining this topic in social formations across Afro-Eurasia during the first two millennia BCE and first millennium CE, allowing scholars to empirically evaluate the varied and contrasting claims researchers have put forward.

We will discuss ongoing work by the Seshat project to explore how various key social features – from increased agricultural productivity to advances in military weaponry and tactics, the growth of increasingly complex societies, and the development of moralizing and universalizing ideology – spread across Afro-Eurasia. We consider the implications of these findings for regions on the western and eastern fringes of Eurasia. Overall, we find that axiality is a more complex, patchy, widely distributed, and temporally extensive phenomenon than the original advocates of the concept conveyed.

In this session, we will survey the results of an extensive cross-cultural survey of past societies from western Europe to East Asia covering the last 6,000 years which suggest that the ideological and philosophical developments seen as hallmarks of the Axial Age actually arose late in the sequence, contrary to most traditional interpretations of the epoch. These cultural adaptations only became prevalent in societies that had experienced a sharp rise in social complexity, a process itself directed largely by the opportunities and demands of increased agricultural productivity and intense inter-state competition.

5 TESTING THE AXIAL AGE CONCEPT APPLIED TO ETRURIA IN THE CONTEXT OF FAR WESTERN ASIA

**Abstract author(s):** Stoddart, Simon (University of Cambridge; University of Kiel)  
**Abstract format:** Oral

The paper will examine how Jasper's concept of the Axial Age matches up to the data from Etruria. Etruria conforms in terms of providing a cluster of competing city states (one of Jaspers' criteria) in precisely the right period during the first millennium BC. Furthermore, the suggestion by Graeber that coinage may be interconnected with the economic and political changes of the period also appears to hold true. It is, however, very much more difficult to detect in Etruria the much vaunted religious and philosophical changes which are attributed to Greece (and Rome).The literature of Etruria has not been preserved, but the evidence that does exist suggests that Etruscan thought and religion had major differences from those preserved in the generally accepted classical world and from those detected from other Iron Age communities of the same period. The example of Etruria will be set within the

broader context of Iron Age far Western Asia as one tessera in the mosaic of different communities which stretched across the Asian continent in that period.

6 MATERIALS AND IDEAS IN THE SECOND HALF OF THE 1ST MILLENNIUM BCE: COINAGE AND CONCEPTS IN JAPAN AND BRITAIN

**Abstract author(s):** Hutcheson, Andrew (University of East Anglia)  
**Abstract format:** Oral

During the last half of the 1st millennium BCE, in what are now Japan and Britain, there was a flow of exchanged materials from the continent. This had been the case earlier too. There was also increased agricultural intensification and settlement complexity. In Japan there was mass inward migration and we can see this reflected in the record through material similarities to the Korean peninsula, including burials. In Britain the burial record is very limited with relatively few inhumations. Towards the end of the period there was a mixture of materially rich inhumations with some cremation cemeteries. Burials and cremations, where they do exist, often show a conceptual, and materially direct, connection with traditions on the continent. This paper will examine types of archaeological evidence that may be proxies for complex ideas in these contexts. It will consider whether the connection of materials to concepts that were making their way across large stretches of Eurasia at this time, in what Karl Jaspers termed the Axial Age, can be viewed archaeologically. Did the intellectual developments taking place in China, India, Palestine and Greece touch the extremities of the Eurasian continent? Following Graeber, who extended the Axial Age concept to the development of coinage, noting that this happened in the 'core' locations at around the same time (c. 600 BCE), there is a specific material link to examine. Coinage, along with its associated concepts, moved out from its inception locations, reaching Britain around 200 BCE and Japan from China around the same time. In Japan it was not adopted as a practice until much later in the 8th century CE. There are in Japan other materials that were perhaps used in similar ways. This combination of increasing material complexity can be thought about in terms of Ian Hodder's concept of entanglement.

7 WHAT IS A SHRINE? ARCHAEOLOGICAL PERSPECTIVES FROM YAYOI JAPAN AND IRON AGE EUROPE

**Abstract author(s):** Kaner, Simon (Sainsbury Institute for the Study of Japanese Arts and Cultures) - Hutcheson, Natasha (University of East Anglia)  
**Abstract format:** Oral

This paper will review the evidence for the emergence of shrines as a distinct category of archaeological feature (or 'heritage asset') in the Yayoi and Kofun periods of the Japanese archipelago and the European Iron Age, and will consider how the concept of enshrinement is coloured in both areas by epistemologies and ontologies heavily influenced by teleological tendencies drawing on analogies with emerging world religions. In both regions sites identified as shrines often undergo considerable modification through processes of rebuilding and restructuring, facilitating the reconstruction of shrine microhistories which in turn enable interpretation at the local level. In addition, the paper investigates the destruction of shrines, and to what extent this form of desecration became a new form of social practice entangled in discourses of ritualized violence. How was the development of the concept of the shrine related to the emergence of the notion of transcendence, one of the cornerstones of the Axial age?

8 ENCOUNTER PROJECT: DEMOGRAPHY, CULTURAL CHANGE, AND THE DIFFUSION OF RICE AND MILLET DURING THE JOMON-YAYOI TRANSITION IN PREHISTORIC JAPAN

**Abstract author(s):** Crema, Enrico (University of Cambridge) - Bondetti, Manon (University of York) - Brainerd, Leah (University of Cambridge) - Carrignon, Simon (University of Tennessee; University of Cambridge) - Craig, Oliver (University of York) - Kobayashi, Ken'ichi (Chuo University) - Madella, Marco (ICREA - CaSEs, Department of Humanities, Universitat Pompeu Fabra) - Shinya, Shoda (University of York; Nara National Research Institute for Cultural Properties) - Stevens, Chris (University of Cambridge) - Yoshida, Akihiro (Kagoshima University)  
**Abstract format:** Oral

The demic and cultural diffusion event that unfolded within the Japanese islands during the 1st millennium BC is characterised by a substantially diverse set of local responses to the so-called 'Yayoi package', which was brought in by the migrant communities from the Korean peninsula. Archaeological data is indeed increasingly providing evidence of regional variations ranging from swift adoption of the entire package to selective adoption, hybridization, short to long term resistance, and even episodes of reversions. The diversity of these responses eventually led to a forking path that has defined the foundation of the social, economic, cultural, and biological variations in the subsequent centuries. The ERC-funded ENCOUNTER project is currently investigating this pivotal moment in Japanese prehistory by synthesising the available archaeological data through novel computational and statistical approaches and by producing new lines of evidence through biomolecular archaeology. This paper will provide an overview of some of the preliminary outcomes of the project drawing from case studies focused on paleo-demographic reconstructions, crop productivity models, and organic residue analyses.

9

CONNECTIVITY BETWEEN THE JAPANESE ARCHIPELAGO AND MAINLAND DURING AND PRIOR TO THE 1ST MILLENNIUM BC

**Abstract author(s):** Bausch, Ilona (Leiden University)

**Abstract format:** Oral

This paper aims to evaluate the potential for cultural transformations and ideological cross-fertilization from the perspective of trade, with a special focus on the social role of ornaments.

In Japan, the ‘Axial Age’ and globalisation processes that triggered lasting and widespread social change probably truly started during the bronze age of the Yayoi period, due to a great influx of people who brought new technologies and ideas from the Mainland.

However, during the preceding Jomon period, there already existed a special connectivity between hunter-gatherer groups from Northern Kyushu and the Southern Korean Peninsula: long-standing exchange networks featuring raw materials, goods, technologies and ideas. Visible evidence of long-distance exchanges at sites in both regions includes obsidian chunks, finished tools, pottery, clay animal figurines and ornaments.

For instance, HA Insoo has argued that Chulmun hunter-gatherer groups from the Southern Korean Peninsula traded shell bracelets with Jomon groups in return for obsidian from Kyushu. Could—arguably more or less standardised— processed objects such as bracelets have played a role in transmitting value?

Perhaps more importantly, to what extent were practices of bodily ornamentation shared between the Japanese archipelago and the East Asian mainland prior to and during the 1st Millennium BC, and did these exchanges play a role in transmitting ideas and world views?

10

THE LAST 200 YEARS OF THE FIRST MILLENIUM BCE AS THE “AXIAL AGE” IN PREHISTORIC JAPAN

**Abstract author(s):** Matsugi, Takehiko (The National Museum of Japanese History)

**Abstract format:** Oral

The Yayoi period (950BCE-AD250) has long been considered as the first agricultural society in the Japanese archipelago, which gradually developed into a class society in the following Kofun period (AD250-600) characterized by kingly burial mounds. However, recent investigations revealed that the Yayoi period could be divided into two stages entirely different from each other; the early Yayoi before the 3rd century BCE with little metals and non-hierarchical society, and the mid and late Yayoi after around 200BCE with the popularization of iron tools and social stratification.

The epoch around 200BCE is marked by the emergence of chiefly mounded tombs including elite burials, enlarged settlements often with multiple circular moats and a central shrine, inflows of prestige goods such as bronze mirrors, presumably weight and measure and writing system, and coinage from the Chinese continent and the Korean peninsula.

An expansion of the ancient imperial system of the Han dynasty is considered to have promoted the process of increasing social complexity after 200 BCE towards the political integration and early state formation at the end of the Yayoi period.

11

THE SECONDARY PEOPLES’ REVOLUTION AND THE RISE OF THE META-BARBARIAN: COMPARING BRONZE AGE JAPAN AND BRITAIN

**Abstract author(s):** Hudson, Mark (Max Planck Institute for the Science of Human History)

**Abstract format:** Oral

World systems theory argues that core regions exploit and under-develop their peripheries. While this model was usefully applied to the Bronze Age in the 1980s-90s, the concept of ‘bronzisation’ and other contributions from globalisation theory have made it hard to continue to accept Bronze Age world systems. New research shows that Bronze Age ‘peripheries’ in fact played a socially autonomous role in long-distance trade, developing decentralised transcultural features which drew on both centre and margin. Borrowing from James Scott’s re-invention of the term ‘barbarian’ and with a nod to Andrew Sherratt, we might see this period as forming a ‘secondary peoples’ revolution’ (Hudson 2020). This paper will attempt a comparative analysis of Bronze Age ‘meta-barbarians’ in Island East Asia and northwest Europe with a particular focus on Japan and Britain. Archaeological evidence relating to the globalisation of food, trade in metals and textiles, the organisation of violence, and regional variation will be discussed.

12

THE FORMATION OF COMPLEX SOCIETIES AS SEEN FROM RELIGIOUS PRACTICES

**Abstract author(s):** Mizoguchi, Koji (Kyushu University)

**Abstract format:** Oral

This paper investigates the formation of complex societies by examining what changes took place to ‘religious’ practices in the process. For that purpose, the religious is heuristically redefined in terms of their functional-effective elements thus: religious activities constitute a distinct communicative domain that responds to and processes the uncertainties and risks of the world. Drawing upon this re-definition, this paper adopts a procedure comprising the following units of investigation: A) what uncertainties and risks of the world were generated and differentiated in/by a certain social formation, B) how they were responded to and processed, and C) how the mode of the responding and processing changed as ‘social complexity’ developed? The pre- and proto-historic periods of

the Japanese archipelago will be investigated as a case, and it will be revealed that the mode of religious practices changed as the spatio-temporal distribution of the sources of uncertainties and risks to be reacted to and processed changed.

368

A DARK GOLDEN AGE. NEW APPROACHES IN THE RESEARCH OF THE CIRCUMALPINE MIDDLE BRONZE AGE

**Theme:** 6. Material culture studies and societies

**Organisers:** Schwarzberg, Heiner (Bavarian State Archaeological Collection Munich) - Massy, Ken (Ludwig Maximilian University of Munich) - Chvojka, Ondřej (South Bohemian University of České Budějovice)

**Format:** Regular session

The Central European Middle Bronze Age is a period often overlooked as a transition between the emerge of bronze metallurgy and exchange and the spectacular features of the Late Bronze Age Urnfield Culture. Nevertheless, it is a period of crucial social, cultural and technical developments.

Even though some regions bear rich archaeological heritage, our knowledge on the Middle Bronze Age is still limited and in a greater extent based on research carried out in the early decades of the 20th century. When trying to get a general and supra-regional picture of the wider circumalpine region in the mid 2nd millennium BC, it becomes evident that despite active archaeological research the overall state of knowledge is still in arrears.

With this session we want to try to widen our horizons on this fascinating period on a broad scale including new chronological results, key finds and socio-economic features. The goal is to bring together researchers providing new scientific and archaeological evidence to deepen our understanding of the Middle Bronze Age in Central Europe – from Eastern France to Hungary and from the Central German Uplands and Bohemia to Northern Italy.

ABSTRACTS:

1

PRODUCER – TRADER – CONSUMER? BRONZE AGE EXPLOITATION, PRODUCTION AND DISTRIBUTION OF COPPER IN THE CENTRAL ALPINE REGION

**Abstract author(s):** Reitmaier-Naef, Leandra (Deutsches Bergbau-Museum Bochum) - Reitmaier, Thomas (Archaeological Service of the Canton of Grisons) - Schindler, Martin (Archaeological Service of the Canton of St.Gallen)

**Abstract format:** Oral

The fact that access to natural resources is subject to ongoing transformation depending on socio-economic developments can be seen particularly clearly in the example of the inner-Alpine region. This paper focuses on the change in metal use in the central Alpine region with focus on the transition from Early to Middle Bronze Age. Special attention is given to the archaeological and archaeometrical investigation of finds that have not or only insufficiently been considered so far, such as stone tools of primary and/or secondary metallurgy as well as waste products of metallurgical processes from settlement contexts. These finds may shed light on the role local settlements played in the network of copper producers, traders and consumers.

The change in access patterns can be roughly divided into three stages: During an initial phase (EBA), permanent settlements are already present in the Alpine Rhine Valley, but for the inner Alpine area, a seasonal, resource-oriented land use must be assumed. A second stage is reached at the transition to the Middle Bronze Age: In the central Alpine region, an increasing consolidation of the human presence is becoming apparent. In most alpine valleys a network of permanent settlements is emerging. These are small, often fortified settlements at specific topographical locations. The subsistence strategy seems to be based on a combination of agriculture, animal husbandry, alpine pastoralism and the use of mineral resources. Permanent settlement ultimately also led to the expansion of transalpine trade networks to the south and east. At the same time, the ceramic spectrum of the inner Alpine region shows clear references to the northern Alpine foothills, from where the settlement of the inner Alpine region probably started. Finally, in the course of the Late Bronze Age an economic intensification can be observed, which was reflected in a specialization of individual micro-regions.

2

ON THE POSSIBILITY TO RECONSTRUCT THE BRONZE AGE COSTUME ON THE BASIS OF ANALYSIS OF SURFACES OF BRONZE JEWELLERY

**Abstract author(s):** Nožinová, Sona - Křišťuf, Petr (University of West Bohemia, Department of Archaeology)

**Abstract format:** Oral

The poster contribution demonstrates the possibilities of traceological analyses of bronze jewellery while studying the appearance of the Bronze Age costume. It is the jewellery that is one of the main artifact categories of the Bronze age. It can work as a functional piece of clothing, a symbol of belonging to a social group, a means of communicating individual’s special traits, etc. As context We use Bohemian Bronze Age jewellery collections that were a part of grave equipment. The aim of this poster contribution is to answer the following questions: Is the studied bronze jewellery used only for the burial rituals or had the deceased used it during his life? And if it was worn during an individual’s life in the Bronze Age, do wear marks on the bronze jewellery allow us to reconstruct different clothing pieces forming a costume belonging to a specific social class, such as the cases in northern Europe?

3 **BLING FOR ETERNITY – AN EXCEPTIONAL HOARD OF THE MIDDLE BRONZE AGE FROM OBERSTREU**

**Abstract author(s):** Schwarzberg, Heiner (Bavarian State Archaeological Collection Munich) - Büttner, Andreas (Bavarian State Office for Monument Preservation Munich)

**Abstract format:** Oral

An exceptional Middle Bronze Age hoard deposited in a ceramic vessel was discovered by a detectorist in Lower Franconia but eventually recovered und subsequently excavated under laboratory conditions by authorities of the Bavarian State Office for the Preservation of Historical Monuments. The vessel contained the rich ornate of a woman, approximately dating to the 15th century BC, consisting – among other items – of six hair rings of gold wire, a bronze hair clasp, three large necklaces of amber beads and bronze pendants and rings, two wheel headed pins, several tutuli and ringlets of bronze, a sickle fragment as well as two glass beads and certain animal bones.

This talk tries to follow the various traces of the hoard’s items throughout the Old World ranging from the Mediterranean to the Baltic Sea. They shed a light on long distance exchange and ritual beliefs of the Middle Bronze Age in Central Europe.

4 **IN THE MIDDLE OF TODAY’S SETTLEMENTS BUT ALMOST INVISIBLE: AN INTEGRATIVE INVESTIGATION OF A MIDDLE BRONZE AGE SETTLEMENT IN SWITZERLAND**

**Abstract author(s):** Joray, Sophia (Ur- und Frühgeschichtliche und Provinzialrömische Archäologie, University of Basel) - Brönnimann, David (Integrative Prehistory and Archeological Science (IPAS), University of Basel; Ur- und Frühgeschichtliche und Provinzialrömische Archäologie, University of Basel) - Maise, Christian (Archaeological Service Canton of Aargau; Ur- und Frühgeschichtliche und Provinzialrömische Archäologie, University of Basel) - Kühn, Marlu - Rentzel, Philippe (Integrative Prehistory and Archeological Science - IPAS, University of Basel) - Röder, Brigitte (Ur- und Frühgeschichtliche und Provinzialrömische Archäologie, University of Basel) - Doppler, Thomas (Archaeological Service Canton of Aargau)

**Abstract format:** Oral

Prehistoric settlements are not only the location but also the result of culturally determined actions such as everyday practices and special (singular) events. Some of these practices manifest themselves in the archaeological record, e.g. in the organisation of social space, activity areas and architecture; in the waste behaviour; in the use and reuse of resources; and thus in the distribution and preservation of objects.

The integrative research project MAGIA (Middle Bronze Age in the Canton of Aargau Integratively Analysed) aims to analyse Middle Bronze Age settlements in Canton Aargau (Switzerland). The site of Gränichen Lochgasse is a perfect research object for this purpose. Covering an area of about 10,000 m2, the recently excavated settlement is the largest Middle Bronze Age settlement in Switzerland investigated to date. Around 1,000 structures were documented and 170,000 finds (mainly pottery sherds) were recovered.

The reconstruction of site formation processes is one of the first tasks that need to be tackled in order to detect and analyse the aspects mentioned above (organisation of social space etc.). For this, the focus is on characteristic settlement features such as pits, potential ovens, postholes, and piles of heat-affected stones. A theory-based, interdisciplinary approach, which incorporates archaeology, geoarchaeology (micromorphology), archaeobotany and statistics, is used. The combined results will provide information on how the settlement was structured; what daily routines were practiced; how the uses of the site developed and changed over time (from a Middle Bronze Age settlement to a probably partially abandoned Late Bronze Age site where certain (ritual) practices continued); and how the settlement was embedded in the landscape. In addition, statistical methods are used to efficiently evaluate large quantities of finds. Using these methods, the project will cast light on the dark but golden period of the Middle Bronze Age in Switzerland.

5 **MIDDLE BRONZE AGE LAND USE DYNAMICS IN THE NORTH-WESTERN ALPINE FORELAND**

**Abstract author(s):** Höpfer, Benjamin - Scherer, Sascha - Kühn, Peter - Scholten, Thomas (University of Tuebingen) - Knopf, Thomas (University of Tuebingen; Keltenmuseum Hochdorf/Enz)

**Abstract format:** Oral

Given that many Middle Bronze Age (MBA) settlement sites have been discovered in many parts of the north-western Alpine since the end of the last century, one of the most striking aspects of this time – apart from the funeral habits – is by now its site density. More specifically, the increase in settlement density does not only show in agriculturally favourable areas but also in harsher landscapes. As these dynamics occurred during a period of climatic deterioration, it seems clear that strictly nature-deterministic models will not be able to provide satisfying explanations.

After outlining the record in the Hegau near Lake Constance and the Western Allgäu, this talk will focus on three sites that were investigated more closely by the Tuebingen CRC 1070 RESOURCECULTURES. Anselfingen, being one of the most completely excavated settlements and an important example in the wider area, supports the notion that there were certain peculiarities in the architecture and organisation of MBA settlements in the region. Archaeopedological, zoological and botanical analyses shed further light on subsistence practices like crop farming, stock breeding and forest management, which seem to exhibit characteristics already known from the Early Bronze Age in the region, while a 2 kg copper cake fragment could be chemically provenanced to the Mitterbergrevier, showing that the area was indeed supplied from the Eastern Alps during the MBA. Around Leutkirch, we were able to confirm the age and character of a small hillfort and found evidence for a contemporary cemetery next to the hilltop, for “regular”

settlements and for subsistence farming in the adjoining valley. They show that this “unfavourable” landscape was properly settled during the MBA – possibly because technological innovations allowed for it, but maybe also because reliable, local infrastructures were a key resource in the consolidation of long-distance trade networks?

6 **MIDDLE BRONZE AGE HILLTOP SETTLEMENTS ON THE SWABIAN ALB**

**Abstract author(s):** Spatzier, Andre (Landesamt für Denkmalpflege Baden-Württemberg)

**Abstract format:** Oral

The Swabian Alb is well known for its burial mounds of the Tumulus culture, but little is known about MBA settlements, although there is evidence of possible habitation sites because of stray finds. Even in the regions south of the Swabian Alb our knowledge remains scarce, regarding both mineral soil and lake side settlements, since the few excavated sites have only been published as preliminary reports and not been studied in detail.

Open settlements can hardly be detected by prospection but are normally found in the course of excavations. In contrary, at fortified sites, particularly in elevated locations, preserved defensive structures and clearly defined areas facilitate purposeful field research.

The topography of the Swabian Alb, particularly its northern fringe, has excellent conditions for protected settlements on promontories and hilltops. Steep slopes provide natural protection on most sides, minimizing efforts to build defensive structures such as ditches and banks. Consequently, many fortifications dating back into prehistory are located here. A number of fortifications have been examined with cross sections since the late 1800s. However, no clear evidence for MBA hilltop settlements have been detected until now.

A project of the State Office for Heritage Management Baden-Württemberg aims to advance our understanding of EBA/MBA hilltop settlements in Southwestern Germany. Recent excavations provide evidence for a MBA fortified site in a “hidden” position neighbouring the Danube valley near Ulm. A cross section at one of the two fortifications structures yielded likely Bronze age sherds; charcoal samples the base of the bank will clarify its dating. Detector finds from the inner area exclusively belong to the MBA, confirming the supposed dating of the site as indicated by find collections mainly from the 1930s. The excavations on this site and other possible EBA/MBA hilltop sites will continue in spring 2021.

7 **MIDDLE BRONZE AGE EQUALS TUMULUS CULTURE? - NEW MIDDLE BRONZE AGE BURIALS FROM SOUTHERN BAVARIA**

**Abstract author(s):** Massy, Ken (LMU Munich)

**Abstract format:** Oral

Southern Bavaria was one of the main areas to define the Middle Bronze Age material culture and burial customs in Central Europe. This also led to the term “Tumulus Culture”, which is still in use today by some researchers to describe the entire Middle Bronze Age. The major issue is that most excavations were carried out in the beginning of the 20th century or before, which also explains the focus on tumuli clearly visible in the landscape. Therefore, reliable archaeological contexts are rare, especially considering the small number of Middle Bronze Age burials being unearthed in the second half of the 20th or the beginning of the 21st century.

Recent discoveries in southern Bavaria, especially in the Augsburg region, challenge the notion of a fully evolved “Tumulus Culture” invading the Early Bronze Age landscape and displace former local inhabitants or entirely replace their burial customs by introducing new beliefs. Many of the burials from the first half of the Middle Bronze Age seem to have been flat graves and not tumuli, but breaking with the habit of crouched burials in sex-differentiated orientation. One of the largest sets of radiocarbon dates in Europe from the Middle Bronze Age shed new light on the absolute chronology of Middle Bronze Age material culture. These results are complemented by ancient DNA and isotopic analyses.

8 **THE MIDDLE BRONZE AGE IN SOUTH BOHEMIA: DARK OR GOLDEN PERIOD?**

**Abstract author(s):** Chvojka, Ondrej (University of South Bohemia) - Hlášek, Daniel (Institute of Archaeology CAS in Prague) - Šálková, Tereza - John, Jan (University of South Bohemia)

**Abstract format:** Oral

The Middle Bronze Age (MBA) was more or less on the fringes of research interest in Bohemia in last decades. In the first place, this situation was caused by the limited occurrence of some types of attractive sites. Compared to the Early Bronze Age and Urnfield period, there are almost no fortifications or hoards of metal artefacts. Second factor was the decrease in number of tumuli graves excavations, which are still one of the main sources of knowledge of that time. In recent years, however, this situation has improved, as shown by a number of examples from the area of the southern Bohemia. In the presentation we will focus on the main issues currently related to this epoch (e.g. chronological definition, settlement structure, subsistence, analysis of metal artefacts and long-distance contacts). Thanks to many rescue excavations and research projects, a number of settlements have been explored in the last 30 years, many of which have provided essential finds important for finer chronology, long-distance contacts, subsistence strategies and the ideological sphere. A detailed evaluation of the artefacts and newly conducted research proved the existence of several MBA hillforts, hitherto dated only to the Early Bronze Age,. Several burial mounds were modernly excavated and several hoards clearly from the MBA discovered. Isotopic analyzes confirmed the dominant presence of copper from Alpine deposits. From

the point of view of agriculture, we observe the onset of new types of cereals at this time (millet). According to the current state of knowledge, we can thus rehabilitate the MBA as an epoch with equally important sites, as in other phases of the Bronze Age. Undoubtedly, this is a period of cultural change, but there is no indication that these are changes for the worse.

## 9 RADIOCARBON DATA MODELS OF THE MIDDLE BRONZE AGE IN MORAVIA

**Abstract author(s):** Šabatová, Klára (Masaryk University) - Parma, David (Archaeological Heritage Institute Brno)

**Abstract format:** Oral

Radiocarbon dating makes it possible to bridge temporal and geographical differences and change the view of traditional themes of the Central European Bronze Age, which have long been dominated by cultural and periodization schemes. The challenge is to collect data from time periods that are underrepresented in the archaeological record, as is the case with the Middle Bronze Age in Moravia in the Czech Republic (1600–1300 BC in the local chronology), which is characterized by a change in the nature of the archaeological record. There is a distinguishable shift in the occupation pattern, which is irregular and, compared to the Early Bronze Age, the registered sites have only low representation in the archaeological record.

The objective of this paper is to briefly demonstrate the character of Middle Bronze Age archaeological sources in Moravia and, based on radiocarbon models, synchronize the early and middle stages of the Middle Bronze Age in Moravia with the development of the Carpathian Basin and the Danube Region. The set of new radiocarbon dates obtained from graves associated with the Koszider horizon enables us to describe the process of how the period begins. Sets of radiocarbon dates from settlements make it possible to demonstrate the structural change reflected in the settlement pattern.

## 10 THE MIDDLE BRONZE AGE IN AUSTRIA - A PERIOD OF CONSOLIDATION AND TRANSFORMATION

**Abstract author(s):** Krenn-Leeb, Alexandra (Department of Prehistoric and Historical Archaeology, University of Vienna)

**Abstract format:** Oral

The formation and establishment of the Middle Danubian Hügelgräberkultur may have covered a relatively short period of time. However, it was marked by profound social and societal changes. Among other things, this is primarily visible in the fundamental change from inhumation to cremation. At the same time, however, there is much to suggest a period of stabilisation and consolidation at various levels and structures of social life. A habitus observable beyond the region speaks for a comparable social organisation that must have been successful in creating identity. It will also have been reflected in the political structures. Some of the observed actions and processes were consolidated in the course of the Middle Bronze Age. Ritual practices are definitely part of this and they become part of mental communities. Particularly in the economic sphere, a clear professionalisation can be observed, such as in the organisation of metallurgy, especially in the extraction and processing of the raw material copper, as well as in the obviously routine distribution of the resulting bronze objects.

In the course of the extensive large-scale excavation projects of recent years, several new Middle Bronze Age features were discovered in Austria. Their comprehensive documentation allows a re-evaluation of some well-known and important contexts. On the basis of recently documented and re-evaluated contexts of features, the lecture aims to give broader perspectives on settlement, burial and deposit practices in the Middle Bronze Age in Austria on the basis of social archaeological considerations.

## 11 DOES THE POPULATION OF THE DEAD REFLECT THE ONE OF THE LIVING? THE CASE STUDY OF OLMO DI NOGARA CEMETERY

**Abstract author(s):** Cupitò, Michele - Vicenzutto, Daivid (dBC - Università di Padova)

**Abstract format:** Oral

The Olmo di Nogara cemetery, located in Verona plain and belonging to mid-16th - mid-12th century, represents, as is well known, one of the most important funerary contexts of the European Bronze Age. The increase in data that followed its publication and the many bioarchaeological studies carried out on the exceptional anthropological sample, has marked a turning point in the understanding not only of the funeral rituality, but also of the terramare social organization – in particular the north Po plain ones – in the 400 years of their historical trajectory. Both for reasons of time and, above all, to investigate new issues, the paper does not have the objective to frame the cemetery nor to return to the topic of the social structure. Limiting the analysis to the central phase of the Middle Bronze Age, the paper focuses on how much and in what terms the funeral population of the Olmo cemetery reflects the real structure of a terramara community lived in the chronological horizon mentioned, both in terms of quantities and of the composition by sex and age. Since the settlement referred to the cemetery is not known, the Olmo necropolis will be compared with the Muraiola terramara, also located in Verona plain. This settlement, indeed, is related to a funerary context, which is the Gambaloni cemetery. This necropolis, although only marginally known as it was investigated in the 1800s, presents the same aspects of the Olmo one, at least for the Middle Bronze Age phases. Specifically, the population estimates obtained from the funeral sample will be compared with those calculated from the Muraiola population using the housing areas. Moreover, the population data will be integrated with life tables of pre-industrial agricultural societies of the recent past.

## SOMETHING OLD, SOMETHING NEW, SOMETHING BORROWED AND SOMETHING IMPORTED!

**Abstract author(s):** Mavrovic Mokos, Janja (University of Zagreb Faculty of Humanities and Social Sciences Department of Archaeology)

**Abstract format:** Oral

This title is a great representation of the developments in the Middle Bronze Age of continental Croatia, an area that can be divided into four smaller parts exhibiting different cultural elements. What they all have in common is a pronounced local component and an autochthonous development (something old). Due to the favourable geographical position dominated by three important communication routes, rivers Sava, Drava and Dunav, the influence from neighbouring areas can be seen in the local component (something new), while the exchange of ideas can mostly be seen in the decoration of the ceramic material – the Tumulus culture's nipple like decoration and appliques with a triangular cross-section, as well as the stamped ornament from the Szeremle group (something borrowed). It is important to note that new decorations almost always appear on the local pottery forms. The dynamic of the exchange of goods and the extent and scope of the communication routes that have branched out over the entire central Europe are best exemplified by the imported items. From amber and the Brotlaibidols, metal finds from the Koszider horizon and the Hungarian battle axes, to the imported ceramic material. Even though this is an extremely interesting and dynamic period, there are very few reliable, closed and recently excavated contexts in Croatia. Almost no analyses have been conducted, so the interpretation still depends on the typology of the ceramic material. The presentation will contain an overview of data regarding the Middle Bronze Age of continental Croatia, as well as all the challenges our colleagues face while interpreting segments of that period. The Middle Bronze Age currently seems to be providing more questions than answers. To change this, the presentation will offer ideas for their solution. Besides, science is about asking questions, isn't it?

## 13

## MOMENTS BEYOND DARKNESS — ON THE BORDER OF GOLDEN AGES ALONG THE DANUBE IN THE MID-2ND MILLENNIUM BC

**Abstract author(s):** Kulcsár, Gabriella - Kiss, Viktória (Institute of Archaeology Research Centre for the Humanities)

**Abstract format:** Oral

The present paper focuses upon the absolute chronology of sites and social transformations which can be dated to the end of the Middle Bronze Age and the first phase of the Late Bronze Age in Hungary. The Middle Bronze Age 3 phase or the so-called Koszider period in Hungary is traditionally dated between 1600 and 1450 cal BC. This phase is characterised by the uniformisation of distinct MBA pottery styles that can be explained by the increasing intensity of contacts between communities within the Carpathian Basin, as well as by the transformation of identities. The cardinal issue in beginning of the Late Bronze Age – in correlation with the Central European Middle Bronze Age – is the appearance of the new material culture of the Tumulus culture. We can observe the transformation of metal supply, and changes in the settlement system parallel with the abandonment of the tell settlements. In order to examine the processes of the mentioned time period we will make an overview of several recent finds from the central part of Hungary, completed by new AMS radiocarbon dates from closed burial assemblages and settlements.

## THE TANGIBLE AND THE INTANGIBLE: NEW VISTAS ON CULTURAL HERITAGE DOCUMENTATION AND MANAGEMENT

**Theme:** 3. The new normality of heritage management and museums in post-Covid times

**Organisers:** Chroni, Athina (General Directorate of Antiquities and Cultural Heritage-Hellenic Ministry of Culture and Sports-Hellenic Republic; National Technical University of Athens-School of Rural and Surveying Engineering-Department of Topography-Laboratory of Photogrammetry) - Silver, Minna (Commission I in Application of Recording, Documentation and Information Management for Cultural Heritage in CIPA Heritage Documentation under ICOMOS and ISPRS; Virtual Archaeology Review)

**Format:** Regular session

The balance between the tangible and the intangible space, i.e., the physical and the virtual space, has changed in recent decades and especially in last years. This change has been accelerated by the pandemic of COVID-19, leading to a massive implementation of new technologies and approaches concerning cultural heritage management, and, consequently, museums and museology. The application of remote sensing and GIS for defining a location and carrying out monitoring and management of heritage sites using digital data, have led to a model of continuous remote management of cultural heritage, in its primal stage. Proceeding to a second stage, i.e., cultural heritage management under the perspective of its communication to the public, digital methods, including application of virtual dimensions, are also widely applied in museums, forming a framework proved to be effective in unexpected emergency situations, such as that formed by the pandemic of COVID-19, thus maintaining the thread of society's communication with culture even in a lockdown. Would this framework, characterized nevertheless by new possibilities and constraints, be the leading one in the future?

1 INTRODUCTION

**Abstract author(s):** Chroni, Athina (Ministry of Culture & Sports-Hellenic Republic; National Technical University of Athens) - Silver, Minna (University of Oulu)

**Abstract format:** Oral

Cultural heritage has an essential role concerning individuals’ interaction and social inclusion, as well as economic regeneration.

Unfortunately, Covid-19 pandemic crisis had a huge impact on society and economy, leading to the apparent need for reinventing the common values that connect people worldwide, thus becoming a catalyst for positive changes.

The “new normal” as shaped out has made clear that digital technologies show the way out by creating new models for scientific collaboration, developing innovative techniques for cultural heritage management and, also, proposing hybrid methodologies for social involvement.

Remote sensing, GIS, virtual reality, as alternatives for an integrated cultural heritage management system, combined with open access procedures for sharing access to an extraordinarily rich offer of cultural content, form only a part of new technologies’ vast universe, the rational use of which could effectively contribute to safeguarding and promoting cultural heritage and its inherited systems of values and cultural expressions as part of the shared commons, while giving it a central role in the life of societies. Cultural infrastructures, such as museums and other cultural facilities, should be used as virtual civic spaces for dialogue and social inclusion, thus fostering social cohesion.

Nevertheless, the aforementioned framework is characterized by new possibilities and constraints as well: people’s community has gained indefinite access to the intangible; on the contrary, the society has been deprived of the tangible. Preserving the social fabric and maintaining economic stability, should form our priority in the near future. Widening cultural horizons, invigorating scientific cooperation worldwide, reinforcing and restoring the democratic dimension of culture, should be the ultimate goals.

2 IOANNINA 1430-1913: LINKING THE TANGIBLE TO THE INTANGIBLE. “IASIS”- INTEGRATED SYSTEM FOR REMOTELY MANAGING AND ACCESSING CULTURAL HERITAGE

**Abstract author(s):** Chroni, Athina (Ministry of Culture/Hellenic Republic; National Technical University of Athens) - Georgopoulos, Andreas (National Technical University of Athens)

**Abstract format:** Oral

The specific paper forms part of the Postdoctoral Research Project, implemented by A.Chroni and supervised by A.Georgopoulos, focusing on Ioannina city’s, Greece, Ottoman period (1430-1913) and its multicultural profile as depicted in buildings, public or private, religious or secular, conventional or more elaborate, i.e., cultural heritage that survived in the collective memory of the city.

Unfortunately, Ioannina has undergone major alterations of its urban web. Tracing the pluralistic physiognomy of the city, studying the osmosis of its three cultures, Christian, Jewish and Muslim, and figuring out the related cultural palimpsest has been the great challenge of the specific research project.

The 3D digital approach for certain landmarks of the city as well as the development of an integrated system for monitoring, documenting, protecting and highlighting cultural heritage have formed the main axis of the project, which, under the perspective of a cultural heritage-open access approach, is offered as an open access digital product, via a participatory interactive web-based platform (IASIS: <https://athinachroni.wixsite.com/my-site-1>), a virtual museum (IOANNINA, 1430-1913: <https://www.artsteps.com/view/5feca5aafe659e68d58a48c8>) as well as via QR tags set at the physical sites where the landmarks used to stand, furnishing information and proposing cultural walks in the city, in order to activate, primarily, the local community in the direction of participation in culture and in matters of preservation of cultural heritage, thus reinforcing and restoring the democratic dimension of culture and, also, proposing innovative techniques for safeguarding cultural heritage, maintaining the thread of society’s communication with culture even in extreme situations, like the COVID-19 pandemic, rebuilding our societies and economies and, finally, conveying a message of solidarity, hope, and unity.

3 FROM TANGIBLE COINS TO INTANGIBLE LOST HERITAGE: THE ROLE OF NUMISMATIC EVIDENCE IN RECONSTRUCTING LOST MONUMENTS

**Abstract author(s):** Denker, Ahmet (-)

**Abstract format:** Oral

Lockdown situation enforced by the pandemic of COVID-19 has created an unexpected challenge to maintaining the link of society with cultural heritage. The digital technologies have the potential to liberate the historical sites and museums from the strict limitations of unexpected emergency situations like today. The success of the digital technologies in this context depends on their ability in invoking the awe of the real and authentic site. Very relevant to invoking the awe of lost monuments by using digital technologies is the relationship between the ancient architecture and the numismatic images. Ancient coins provide valuable evidence in reconstruction of the lost monuments from which have remained only foundation stones. This paper reflects some reconstruction efforts of the author for which coins were indispensable sources of the superstructures, the most vulnerable parts of the monuments. The

coins to be discussed in detail in this paper were issued by the cities of the Roman Empire in Asia Minor. The importance and fascination of the coins became at once apparent when we try to reconstruct some of the most difficult temples of the Aegean basin: temple of Athena at Troy, temple of Trajan at Pergamum, Temple of Artemis at Magnesia, and finally the temple of Artemis at Ephesus (one of the seven wonders of the ancient world.) The commemoration of these temples on the Roman coinage has left us an impressive inheritance concerning some of the greatest achievements in the history of architecture. The utilitarian function of ancient coins is shown to be worthy of a place in architectural history. Thanks to 3D reconstructions of four lost temples which are presented here, with the help of the ancient coins, the modern viewers perceptually may experience them as the viewers in their hey days.

4 INFORMATION SYSTEM OF IBERIAN POTTERY FOR RESEARCH, TEACHING AND DISSEMINATION

**Abstract author(s):** García-Fernández, Ángel-Luis (Instituto Universitario de Investigación en Arqueología Ibérica. University of Jaén) - Valero-Domenech, Miguel-Ángel (University of Jaén) - Fuertes-García, José-Manuel - Lucena-López, Manuel-José - Molinos-Molinos, Manuel (Instituto Universitario de Investigación en Arqueología Ibérica. University of Jaén) - Moreno-Padilla, María-Isabel (Departamento de Geografía, historia y humanidades. Universidad de Almería; Grupo Patrimonio Arqueológico en Jaén - HUM-357) - Ogayar-Anguita, Carlos-Javier (Instituto Universitario de Investigación en Arqueología Ibérica. University of Jaén)

**Abstract format:** Oral

Pottery is one of the most common find types in many archaeological excavations. The analysis of pottery allows us to understand the evolution of the technology or the commercial relationships among cultures, as well as other interesting topics like the eating habits or the relationship with the environment and other issues related to religious and symbolic patterns. The systematic processing of the ceramic materials is therefore of major importance in the archaeological study. In addition, allowing open access to these materials for the general public greatly helps the dissemination of the discoveries.

In this work we present the results of a one-year project intended to develop a web platform to allow researchers, students and the general public to access the Iberian pottery collection from the Research Institute of Iberian Archaeology of Jaén (Spain) without the need to physically be at the Institute facilities. With this tool, users can browse through the pieces, read about their main features, explore images and 3D models, apply filters to their searches and study the spatial distribution of the materials over the archaeological sites where they have been found. Moreover, the system is also intended to promote debate among the academic community, allowing registered users to propose and discuss changes on the record data. This way, the community contributions will greatly help to improve the quality of the information.

One long-term goal of this project is to provide researchers, students and the general public with a unified, well-founded repository of Iberian pottery, freely available for those interested in the topic. Therefore, registered users from all over the world are also allowed to submit new records with pieces from other Iberian archaeological sites.

5 IS DIGITAL ENGAGEMENT THE “NEW NORMAL” OF POST-CRISIS MUSEUMS? REFLECTIONS FROM THE FINNISH MUSEUM LANDSCAPE

**Abstract author(s):** Hamari, Pirjo (Finnish Heritage Agency; University of Helsinki)

**Abstract format:** Oral

As the COVID crisis hit the museum community, many institutions were forced to close their doors to visitors. In the absence of audiences on-site, many museums turned to increased digital means in their audience engagement activities. The drive behind such efforts lies not only in the need of museums for continued contact with customers, but also in the more profound need to ensure access to culture, something seen as the fundamental right of all citizens especially in times of crisis.

This paper explores the different scales of approaches museums in Finland selected for their digital outreach activities as a response to museum closures, from simple web presences to more advances means of presenting digital heritage content. It discusses the added value of the approaches used and considers what these approaches tell us about the capacity of the sector to broaden its audience engagement in the digital dimension. Finally, it reflects on the sustainability and the transformative power of the new digital audience engagement “movement” – is this how the “new normal” for museums looks like?

6 MOVING OUT -THE PUBLIC (RE-)DISCOVERS CULTURAL HERITAGE GEMS

**Abstract author(s):** Nilhamn, Bonnie (Helsinki University)

**Abstract format:** Oral

The covid-19 crisis has been hard on the European museums even forcing them to close down temporarily. There are however some museums that have coped better with the situation than others. Many of these are situated far away from the busy cities and located on the countryside. Another feature that they share is that they incorporate the environment around the museum as part of their story which makes it easier to design new, Covid-19 proof, museum products. Not only visiting the museum, but also the surroundings, becomes part of the heritage experience. One good example of this are the Dutch museums that are connected to The Hollandse Waterlinies HWLs (Old and New Dutch Waterlines), which combined make an 85 km long a military defence line. The lines were constructed between 1629- 1815 and 1815-1940 respectively. The HWL runs from Fort Naarden to Fort Steurgat in the Biesbosch in order to keep out enemies from the administrative and economic heart of the Netherlands - Fort Holland, by controlling flooding of a chain of inundation fields to a depth of up to a metre. This would have been enough deep to fence off horse chariots

and even panzer vehicles but too shallow for ships. The military air force soon outdated the effectiveness of the HWL. Nowadays the area around the fortresses and castles is protected landscape and part of the Dutch Cultural Heritage and nominated for the UNESCO World Heritage. Use of GIS has frequently been part of the strategy to open up the knowledge of the HWL and make it displayable and accessible for the public.

## 7 SAVING MEMORY BY INDUSTRIAL ARCHAEOLOGY DOCUMENTING AND PRESERVING A CARPENTRY AT THE MUSTIO CASTLE IN FINLAND

**Abstract author(s):** Silver, Minna (University of Oulu) - Silver, Kenneth (Wallon Society in Finland)

**Abstract format:** Oral

Memory refers to an intangible concept. Industrial heritage is rapidly disappearing and a lot of memory along with it is vanishing, if we, who are living periodically so near and surrounded by it overlook the importance of its preservation. The field of industrial archaeology entails the study of material industrial heritage using historical, architectural and archaeological inquiries. In Nordic countries mining industry was started by constructing ironworks often associated with a manor and a workers' village. In Finland mining and ironworks were initiated by the King of Sweden, when Finland was under Sweden. Many such sites have been under historical, architectural and archaeological investigation leading to further documentations. The ironworks at Mustio was first established at rapids providing energy in Southern Finland already in the 16th century. The carpentry of the castle producing building materials such as windows and doors is situated in the neighbourhood but its production ceased in the 1950-1960s. The protected industrial building representing Nordic vernacular architecture housed machinery from the late 19th century and the beginning of the 20th century was used as a storehouse but had deteriorated by the 2010s to such an extent that it needed a speedy rescue operation. In 2019-2020 laser scanning, photographing and manual drawing were carried out to document the wooden building and machinery in situ as well as some products. In the same time the roof and the windows of the building were restored following traditional methods. The machinery was donated to be saved at a museum collection, so although in another location, it is tangibly preserved. The paper presents the process of documentation and preservation of the described industrial site conserving it tangibly, and intangibly by laser scanning and image-based methods.

## 8 INTEGRATED TRITON SHELL USE DOCUMENTATION

**Abstract author(s):** Chroni, Athina (Ministry of Culture/Hellenic Republic; National Technical University of Athens) - Karali, Lilian (National and Kapodistrian University of Athens; Novosibirsk State University)

**Abstract format:** Oral

The study of the past is articulated on three main axes: locating and documenting archaeological relics in order to interpret them and their role in past societies. In recent years, digital methods combined with archival procedures and, also web-based platforms have gained an important role in the field of cultural heritage documentation, while open data is becoming more and more the leading scientific trend.

The introduction of IT systems operating at cultural institutions shows the need for harmonization of the different systems to enable communication and data exchange. This is achieved through the use of standardized models and controlled vocabularies that are being developed, often on a global scale, while GIS applications contribute in tracing and interpreting connections between various locations, thus figuring out trading routes and, consequently, economic and political relations.

The large number and typology variety of Triton sp. shells, of various cultural periods, calls for a fast, efficient way of documentation while ensuring the scientific character of the procedure and the possibility of information exchange and communication between the scientific communities.

Under this reasoning, designing a GIS database, for the digital documentation of Triton sp. shell trumpets or other objects of everyday, practical or symbolic use in the Aegean world in antiquity is considered to be indispensable for better comprehending the social, economic, political, symbolic and, also, environmental context of our past, as well as efficiently overcoming unprecedented crisis like the one caused by the COVID-19 virus, by proposing digital technologies for cultural heritage documentation, thus linking the tangible to the intangible and restoring scientific cooperation worldwide.

## 9 OBELISKS AS GLOBAL HERITAGE? – MAPPING THE OBELISKS OF CHINA

**Abstract author(s):** Langer, Christian (Peking University)

**Abstract format:** Oral

This paper introduces the understudied monument group of Chinese obelisks, hitherto ignored by Egyptology due to an inherent western bias. Based on ongoing research into the transmission of the obelisk to China as a concept and form in modern Chinese commemorative architecture, the monuments are framed as both tangible and intangible global heritage. The benefits of remote sensing and GIS for mapping their distribution, posing specific questions to the dataset, and conservational issues are discussed on several levels. First, remote sensing and inputting resulting data in a GIS allows us to gauge the distribution and prevalence of obelisks not only in Chinese landscapes and commemorative culture but also beyond that. Complementing the Chinese and wider eastern Eurasian data with the well-known western dataset enables us to gain an understanding of the truly global prevalence of obelisks and their possibly constituting a global heritage that transcends time and space, where obelisks are both means and ex-

pression of a global exchange of ideas. This leads to a raised awareness of obelisks as a viable category in cultural heritage. Second, remote sensing here constitutes the combination of using various internet resources together with e.g. Google Earth to establish the existence of individual monuments and then locate them, enabling the input of information in a GIS for further visualizations and analyses. Third, GIS can ultimately be used to assess the potential of obelisks to become heritage at risk. Related questions are whether they are worth saving or can be saved at all; questions that will come up in the context of climate change and China's rapid development, for instance in the Pearl River Delta. Such work is advantageous when field research may not be possible during crisis, e.g. due to a pandemic, although data collection also has its limits under such circumstances.

## 10 “SPHINX”- SYSTEM FOR THE PROTECTION OF HERITAGE. INTANGIBLE AND NATURAL RESOURCES

**Abstract author(s):** Paraskeva, Dimitra (NTUA)

**Abstract format:** Oral

The pandemic plague that has spread throughout the world has also affected our society in all levels, among which our correlation with the cultural-archaeological heritage.

In context of my Doctoral Thesis, an attempt was made to create an innovative system called “SPHINX” for the management of intangible and natural cultural heritage implemented in the region of Boeotia in Greece. This system is a particularly valuable methodological project both for the field of research and for any other area where SPHINX will be applied. This research revealed a very important aspect of Boeotia, its global uniqueness, and in particular its cultural virtues, that are clearly incomparable with any other similar global features, i.e., the prominent Lavdakid circle, one of the two pillars of Greek Mythology and Drama.

The process of mapping was used for the development of the innovative SPHINX system. The system is mainly based on superimposing one –or more- maps on top of one another and constitutes a continuous search of landscapes that, as dynamic and timeless fields of cultural inscription and manifestation, seek their enhancement and interpretation within the sphere of meanings and symbols. The process of compiling maps can bring up, through the projected concept of palimpsest, the continuously vibrating images of the boeotic, in this case, landscape through the complexes of multilayered dynamic topological systems and networks inscribed on holographic surfaces.

The possibility of creating an innovative digital database in order for the SPHINX system to be managed by the general public is noteworthy. This will facilitate on-site and remote monitoring of cultural heritage, broadening human prospects due to the fact that SPHINX is an innovative idea that combines the past with the present seeking a bright future with the ultimate goal of widening human horizons.

## 11 PHYSICALLY CLOSED, DIGITALLY OPENED: THE CASE OF GREEK ARCHAEOLOGICAL MUSEUMS IN COVID-19 ERA

**Abstract author(s):** Xiradakis, Polyna - Karkazi, Elli - Papatheodorou, Anna - Chourmouziadi, Anastasia (University of the Aegean; Museolab)

**Abstract format:** Oral

During the last decades, too much discussion and effort took place regarding museums' digital dimension. However, recently, due to the covid pandemic, the digital interaction between museums and their audience was not an option; it was the only way forward. But how did Greek Archaeological museums respond to this crisis? To answer this question, 'Greek Museums Facing Covid-19' research project was launched. The research focused on whether the 131 Greek Archaeological museums were ready to have a satisfactory digital presence during the closure of their physical activities. We examined whether the museums addressed digitally the lack of visitors in their everyday agenda. The paper focuses on what the archaeological museums offered to the public and how they digitally published the archaeological information. For the data collection, the Hellenic National Cultural Portal 'Odysseus', was used. The data were organized in categories in relation to their digital activities (announcements, multimedia, live streaming, etc). The quantitative research results were examined and a correlation between Lockdown-1 to Lockdown-2 was implemented. Was the transition to digital reality enough to create a positive stance towards the publication of archaeological material? Did archeological objects, in their digital entity, function as narrative tools or was there a regression to an outdated exhibition perception? Were digital objects treated as 'distant exhibits' or the new ontological digital transcription was capable of creating a new reality in terms of access, management, and/or interpretation? Maybe, this is the moment for museums to use their digital world not just as a way to advertise their collections, but as a chance to create alternative ways for presenting the archaeological information, focusing on multiple narratives and interpretations of their exhibits. In the digital sphere there is enough free space for all these procedures and for the active participation of the broader audience to take place.

## A. GREEK MUSEUMS ADJUST TO DIGITAL REALITY. LEARNING (?) BY DOING

**Abstract author(s):** Karkazi, Elli - Xiradakis, Polyna - Papatheodorou, Anna - Chourmouziadi, Anastasia (University of the Aegean; Museolab)

**Abstract format:** Poster

The unexpected covid-19 pandemic crisis called Greek museums to action digitally, as a response to their mandatory closure. Inevitably, rapid adaptations and relative adjustments were imperative. In this climate of dramatic change, Greek museums had the ideal

opportunity to enter the Digitocene Era. Our research is addressing the question of how Greek museums used their digital tools to engage with their visitors, further shedding light on the ways they met the challenge of Covid-19 lockdown. In order to answer the research questions we referred to the Hellenic National Cultural Portal ‘Odysseus’, which has been developed by the Greek Ministry of Culture. Data have been retrieved from the ‘museums unit’ of the portal, including 271 Greek museums. We focused on the first covid-19 lockdown period in Greece, namely from March the 20th until May the 4th 2020. On the basis of data retrieved, it has been evaluated whether the pre-existing digital ground was adequately solid and fertile to build up an integrated digital experience, furthermore whether digital content could function independently and self-sufficiently as a substitute for physical visits.

SOCIAL INTERACTION IN HERITAGE ENVIRONMENTS

**Theme:** 6. Material culture studies and societies  
**Organisers:** Scutt, Win (English Heritage) - Wilton, Antje (University of Siegen)  
**Format:** Regular session

This session invites contributions that investigate how people interact with each other and with the material space and objects around them in a heritage environment, both original and reconstructed. These environments can be landscapes or built environments that have been shaped by past societies - such as a ruined abbey, a stately home or a prehistoric field system; or they can include environments that have been reconstructed on the basis of archaeological evidence, such as a roundhouse or a Roman fort.

A number of disciplines and sub-disciplines, including social interaction research, social archaeology, spatial archaeology and landscape archaeology, recognise space and its materiality as a socially relevant dimension. In social interaction research, one of the important tenets is that face-to-face social interaction is situated in the material environment. This so-called ‘anchoring’ involves actions of co-orientation, co-ordination and co-operation. Any architecturally designed space provides cues to people as to which type of social activity can be, or is likely to be, anchored in it, and people learn to interpret those usability cues as part of their cultural socialisation.

Contributions to this session should help to shed light on how people today interpret the properties of past spaces as a resource for particular types of social interaction. We invite papers that offer case-studies or methodologies for the systematic investigation of social action and interaction in heritage environments. For instance, how do guides and visitors interact with each other, the architecture and the features and objects within? How do modern appropriations of heritage environments inform us about potential past space interpretations and usage? Furthermore, a systematic analysis of social interaction patterns may have applications for the heritage sector in the design and interpretation of heritage spaces.

ABSTRACTS:

1 HERITAGE INDUSTRY, POST-NATION AND MATERIALITY: AN ARCHAEOLOGY OF ARCHAEOLOGY

**Abstract author(s):** Kulenovic, Igor - Iglic, Sara (University of Zadar)  
**Abstract format:** Oral

There is no shortage of archaeological literature discussing various aspects of entanglement between archaeology and the nation. As a matter of fact, the constitution of archaeology as a specifically modernist discursive formation is impossible to imagine outside the wider processes of modernity. The common approach taken in this body of literature is to demonstrate how past-related discourses were mobilized to achieve various goals ranging from nation-building and claims for authenticity to more extreme examples of territorial claims and extermination of whole populations. In this presentation, I will take a different approach. Rather than concentrating on discursive aspects of uses and abuses of the past, the main focus will be on the very materiality of archaeological remains and how they were mobilized to constitute various subjectivities. Drawing on various strands of more-than-representational theory, I will attempt to demonstrate how archaeology and the affordances of material remains it produces were mobilized in completely different contexts during a span of roughly fifty years. The content of this transformation is that archaeological remains are no longer mobilized to constitute a spatial setting for the constitution of subjectivity based on the modernist liberal consensus but rather now operates in the vague space of heritage industry, oriented almost exclusively towards tourism. The case study used to elaborate on some of these issues will be Zadar, a mid-sized coastal town situated at the Adriatic Sea in Croatia.

2 NEW APPROACHES FOR OLD SPACES. USING 3D RECONSTRUCTIONS AS CONVERSATION TOOLS WITH STAKEHOLDERS

**Abstract author(s):** Loy, Aida (Leiden University)  
**Abstract format:** Oral

For my thesis project, I created a 3D model that represented the ideal reconstruction of an Iron Age hillfort in Coaña (Asturias, Spain). This model was created after the collection of all the archaeological data from the site and some information from nearby similar hillforts. The measures and decisions were made following the most plausible reconstruction.

With this model, I then approach different groups of stakeholders of this archaeological site to start a conversation about the hillfort.

EXPLORING A HERITAGE ENVIRONMENT DURING A GUIDED TOUR: A MULTIMODAL SPACE-BASED INTERACTION ANALYSIS

**Abstract author(s):** Wilton, Antje (University of Siegen)  
**Abstract format:** Oral

This contribution reports on a pilot study as part of a larger project that plans to explore how people socially interact in and with an environment that is characterised by “pastness”, i.e. by architectural structures and objects that have been created by a society that is no longer existent or that have been remodelled in the present according to historical and archaeological evidence. The pilot study investigates the relationship between architecture and the interactional space during a guided tour in a Neolithic house model. It draws on three theoretical traditions and fields of investigation which share an interest in the appropriation of space and its materiality as a socially, institutionally and educationally relevant dimension. These fields are social interaction research, archaeology, and museum studies.

The study presented here is a qualitative study with a selected group of people and uses video-based interaction analysis as an observational approach documenting the process of people moving through and interacting in a heritage environment. The architectural structure consists of a Neolithic house in construction on the grounds of a World Heritage Site which is in the process of being turned into an archaeological park.

The analysis shows how participants in the guided tour systematically incorporate the material environment in the sequentiality of their interactions both as a space to be used and a space to be viewed. Furthermore, the data reveals how participants manage to incorporate embodied and sensual experiences in their exploration of the environment, without breaking away from the interactional format of a guided tour that is primarily focused on reflective (cognitive) activities.

IMPROVING SOCIAL INTERACTION AND ENGAGEMENT ON HERITAGE SITES

**Abstract author(s):** Scutt, Win (English Heritage)  
**Abstract format:** Oral

This presentation will examine how a heritage site can be evaluated in terms of its affordances to visitors. An interpretation scheme for a heritage site involves devising an experience for visitors. While many such schemes focus on the visitors’ cognitive experience – on what they might learn and understand about the site’s archaeology and history – there is also an opportunity to create a social and emotional experience.

The motivation to visit a heritage site is more than just a wish to learn about the past. It can be born of a wish for a day out with friends or family, or to sense physically and emotionally a new environment.

In designing interpretation schemes for heritage sites, it is important to understand how we want visitors to navigate and engage with the site. This does not mean that we must always rigidly control the visitor journey, although this will be desirable on sensitive sites. But we do need to be aware how our scheme will offer opportunities for social and individual experiences.

This paper will summarise a study that aims to assess the potential to improve social interaction and engagement on heritage sites. A methodology is proposed for assessing the opportunities afforded by the pathways and points of interest within a site to different group profiles. Then, we shall apply the methodology to sites in the UK such as Tintagel Castle and suggest how we might alter the design of the sites to afford new embodied experiences.

THE ARCHAEOLOGY OF THE POST-MEDIEVAL RURAL HOUSE: CHALLENGES AND APPLICATIONS FOR A CULTURAL HERITAGE IN THE MAKING

**Abstract author(s):** Bizzarri, Giulia (Università degli Studi di Genova)  
**Abstract format:** Oral

When looking at European approaches to the post-Medieval rural house as cultural heritage, archaeological methods have been involved very differently, going from an integration of archaeology with other disciplines studying the rural house (e.g. cultural anthropology, ethnology, geography) in some research contexts to an almost inexistent contribution in others. Specific aspects to the archaeological study, such as the focus on materiality and context, and the interest for the historical dimension of artefacts (material culture and built environment) allow to delve deeper into researching the specific cultural, social and economic settings within which a house was built, modified or abandoned, and the various ways, through which individuals interacted with these buildings. This contribution will give an overview of different approaches to the heritage management and heritagisation processes of the post-Medieval and late Modern rural house across different European examples. The study will look at historiographical developments concerning the interest toward post-Medieval rural contexts and buildings, providing a background to the approaches to the study of rural houses and their recognition as cultural heritage. The author will then analyse and argue for the specific potential

of archaeological methods within heritagisation processes. Case studies and examples will draw from research and projects from different countries across Central (Austria, Germany), Southern (Italy, Spain) and Atlantic (United Kingdom) Europe, exploring the connections between theoretical approaches, national and/or international policies and public perception of rural built heritage in different contexts (museums, parks, exhibitions). The study seeks to evaluate how the present or absent contribution of archaeological methods has influenced the making of heritage in these spaces, and how differently the wider public, and the various social groups and identities that are to be found within it, has interacted with these contexts, also considering challenges and future possibilities of approaches and responses to this specific cultural heritage.

6 NOTHING TO BE SEEN... FORCED LABOUR ON THE TEMPELHOF FIELD IN BERLIN 1940-1945

**Abstract author(s):** Misterek, Kathrin (Freie Universität Berlin)

**Abstract format:** Oral

How do we remember events whose material reminders we do not see? What if other events' material manifestations dominate both the physical and the memory space?

Today, the Tempelhof Airfield in Berlin is a vast recreational area. Since 1722, it had been a parade ground for the Prussian Army, a test ground for military aviation and a civil airport. During the Nazi period, thousands of people from several European countries were imprisoned in three large barrack camps on the airfield and forced to work for the armaments industry. 1945-1993, the airfield was used by the US Air Force and, 1951-2008, as a civil airport as well.

Most people in present-day Berlin remember the airfield as the focal point of the Berlin Airlift in 1948/1949, when airplanes of the Western allies supplied the West-Berlin population, and as the "gate to the free world" during the Cold War. The airfield's Nazi past, however, is barely known. In part, this results from the multiple layers of memory and meaning ascribed to the airfield for its post-war significance, but in part also from the lack of representation and visibility of the Nazi crimes, since the barrack camps were entirely demolished after the war.

During an international workshop with young adults in 2018, we temporarily marked the outline of three former barracks in order to see how reconstructing the physical scale of the barracks may stimulate visitors of the airfield to engage with this forgotten history and foster conversations about the systematic nature, the ubiquity and visibility of Nazi crimes. Based on this workshop, I propose to create a new visibility by building landmarks and to employ the multivocality afforded by the structures still visible today, thus changing the layout as well as the interpretation of the espace perçu (see Lefebvre's "La production d l'espace").

7 THE CHURCH OF OUR LADY OF ITRIA: THE HISTORICAL SPACE AND ITS MATERIALITY IN THE TERRITORY OF SELEGAS (SARDINIA)

**Abstract author(s):** Soddu, Ottaviana (archeologo libero professionista)

**Abstract format:** Oral

The objective of this contribution is the synchronic and diachronic reading of the forms of territorial occupation in a portion of the countryside of Selegas (Sardinia, Italy), which is of great historical interest due to the presence of a small medieval church that reuses Roman masonry in opus latericium and opus listatum and for the discovery in 1935 of the largest and most well-known Neolithic female marble statue in Sardinia, "the Mother Goddess of Turriga" exhibited at the National Archaeological Museum of Cagliari.

The church dedicated to Our Lady of Itria, much venerated by the community until the twentieth century, is located outside Selegas town in an area characterized by flat areas and gentle and fertile hills.

The study, conducted through the integration of written and oral testimonies, the analysis of cartography and aerial photos, and surface research, highlighted very numerous archaeological presences, evidence of a territory inhabited and used by people since prehistoric times, particularly including structures and materials from the Nuragic, Roman and medieval periods. The data provided by material culture, landscape, social archeology, documentary and cartographic sources show how people have interacted with each other, with the "historical space" and how the landscape was shaped over the centuries.

375 ARCHAEOLOGY, LANGUAGE AND LANDSCAPE

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Klir, Tomas (Charles University, Faculty of Arts, Department of Archaeology) - Zschieschang, Christian (Serbski institut – Sorbisches Institut, Wótnožka za dolnosorbiske slěženja – Zweigstelle für niedersorbische Forschungen, Chóšebuz – Cottbus) - Jansens, Nicolas (Heidelberg University, Institute of Slavic Studies; Charles University, Faculty of Arts, Department of Archaeology)

**Format:** Regular session

The investigation of geographic names against a background of archaeological knowledge is an important field of inter-disciplinary research. The toponymic systems of the past and their remnants, as preserved in historical written sources, inform us about many aspects of the life of former human communities within their respective environments; in particular, (i) the language, social system and economy of initial settlers, (ii) the transfer of information about the landscape and economic resources between human groups

in periods of language- and cultural contact, (iii) the meaning of a given landscape for its inhabitants. Linguistic findings pertaining to these aspects can contribute greatly to archaeological research.

We would like to bring together such interdisciplinary research approaches from various parts of the world. Thus, we welcome papers on the issues of colonization of unfamiliar landscapes, settlement expansion and the phenomenology of landscape and language contact, especially if they combine archaeological and linguistic sources.

ABSTRACTS:

1 NAMING HILLS, CREATING LANDSCAPES: AN APPROACH TO THE SOCIAL CONSTRUCTION OF THE MALDONADO HILLS, URUGUAY

**Abstract author(s):** Aguirrezábal, Diego (LAPPU/FHCE/UDELAR)

**Abstract format:** Oral

This presentation seeks to show how, from the investigations carried out in the Sosa hill range, in the department of Maldonado, Uruguay, various historical processes of invisibility and concealment are revealed at a political, economic and social level. The results of these investigations, have revealed both tangible and intangible elements of the exercise of power at various levels. The environmental context of the range of hills in the east of Uruguay, is especially particular, for its articulation between chains of hill ranges to extensive plains that are mixed with lowland environments and sea coast. In this context, the Sosa hill range stands out for the development of specific processes for the formation of natural rock shelters, which have been used by human groups for at least 7500 years. This extensive process of occupation and the social construction of this landscape, has material manifestations of a complex heterogeneity, inside and outside the shelters. Despite some approaches made by amateurs at the beginning of the 20th century, this evidence had not been previously taken into account by teams of archaeologists in almost 50 years of development of the profession in Uruguay. This produces an invisibility of certain ways of constructing and controlling this territory, in a material and a symbolic way, despite the important evidence that existed in nearby regions such as southern Brazil, Buenos Aires Province, or Patagonia and the abundant indigenous toponymy. Also, this approach to the occupations of the eastern hill range shelters, allow to interpret other social processes, from the first occupations until the contact with the European empires. The articulation of the archaeological evidence together with ethnohistorical documentation allows us to analyze territorial control strategies and to know the historical and colonialist processes leading to invisibility of the pre-Iberian socio-cultural roots in the region.

2 BETWEEN THE PLACES OF FLORISTS, ARCHERS, FEATHERS AND STONES. REINVENTING THE SIGNIFICANCE OF TETZCOTZINCO IN THE PRE-HISPANIC ACOLHUACAN

**Abstract author(s):** Prusaczyk, Daniel (Institute of Iberian and Ibero-American Studies, University of Warsaw)

**Abstract format:** Oral

The study of indigenous toponyms in the area of Mexico is an important element of linguistic studies, especially on the pre-Hispanic Nahuatl language. Mexican place-names are sometimes used in archaeological research and can provide a variety of information about the Mesoamerican history, worldview or religion.

The toponyms occurring in the area of Acolhuacan (the eastern part of the "Aztec Empire") seem to be particularly interesting. The study of place-names in this region is especially important in areas where modern buildings do not allow access to archaeological materials. Analysis of local, indigenous toponyms expands our knowledge about Acolhuacan and helps us understand its history.

The study of such toponyms allows, among others, for a better understanding of the function of the famous site of Tetzcotzinco and its relationship with the rest of the region. Thanks to such analysis, it is possible to understand the archaeologically elusive significance of Tetzcotzinco and other places located within the local network of roads and aqueducts. The study of place-names seems to provide a wealth of information about their pre-Hispanic trade, crafts, landscape and even the history of local rulers. Toponyms can also help us understand the genesis and history of Tetzcotzinco and its relation with Acolhuacan's capital, Tetzcoco.

The main goal of this paper is to present interdisciplinary research on the role of Tetzcotzinco in the pre-Hispanic landscape and an attempt to understand the network of relationships between this place and other settlements in Acolhuacan. The proposed paper will present the results of various studies, including archaeological documentation, studies of pre-Hispanic maps and colonial documents, landscape archeology, and historical and geographical analyzes. As a result of the aforementioned research, we also work on the GIS database which will present a hypothetical network of political, commercial and economic ties around Tetzcotzinco and the city of Tetzcoco.

3 THE ALVASTRA PILE DWELLING: A NEOLITHIC SETTING FOR THE COLLECTIVE FEMALE DEITIES, THE DÍSIR

**Abstract author(s):** Battaglia, Frank (College of Staten Island/ City University of New York)

**Abstract format:** Oral

Receiving sacrifices until the 10th century, and giving name to Swedish assemblies until the 13th, dísir were significant Scandinavian deities. Late texts report them as guardians of individuals or families.

4

PLACE-NAMES, LANDSCAPE AND ARCHAEOLOGY IN THE RECONSTRUCTION OF THE WEST SLAVIC EARLY MIDDLE AGES

**Abstract author(s):** Zscheschang, Christian (Sorbisches Institut, Zweigstelle für niedersorbische Forschungen)

**Abstract format:** Oral

Already for many decades onomastic research has made contributions to the reconstruction of Slavic and German settlement history by indicating certain areas of early settlement. The methodological background expands upon the fact that there are a number of types of place-names that have a rather archaic character. In many cases, these names cluster significantly in certain regions. Such onomastic landscapes can indicate early medieval areas of Slavic settlement. Often, but not everywhere, they correlate with the spread of archaeological finds deemed connected to early Slavs.

This method should not be applied mechanically, but requires careful consideration of extra-linguistic circumstances, and the limitations of statistical significance should be observed. Furthermore, a comprehensive linguistic analysis of the totality of place names is an essential requirement for area studies. Moreover, it is possible also outside of the Slavic language area to chronologically classify place names in a similar way.

Minor place names (or field names) offer still deeper insights into the landscapes of the past. They refer to certain features of the natural and cultural landscape, e.g. to locations of deserted settlements. As a general rule, every analysis of an archaeological excavation or survey should be accompanied by an onomastic study!

All mentioned aspects will be discussed by means of several examples from East Central Europe on the basis of more than 20 years of onomastic research in multi-disciplinary projects.

5

DIGGING ON THE EDGE. THE EARLY HISTORY OF THE POLISH-RUTHENIAN BORDER ZONE

**Abstract author(s):** Woloszyn, Marcin (Institute of Archaeology, University of Rzeszów; Leibniz Institute for the History and Culture of Eastern Europe - GWZO) - Zscheschang, Christian (Sorbisches Institut, Zweigstelle für niedersorbische Forschungen)

**Abstract format:** Oral

In the very east of Poland, directly at the present Ukrainian border, there are several impressive hillforts. Some of them belong to the so called Cherven' Towns which were mentioned in (Ruthenian) written sources by the description of the Polish-Rus conflicts from the 10th and 11th centuries. Over the last one hundred years, they have been investigated many times by archaeologists. But, due to the complex circumstances of the 20th century, many of the findings were stored in archives that were for decades inaccessible to the public or for scientific research.

In the last ten years, efforts have begun to re-collect and analyze this material. The area can be seen in the local (Polish-Ukrainian) but also broader perspective (contact zone between Latin Europe and the Byzantine Commonwealth). The latter is of enormous importance for European history.

The multi-disciplinary investigation of these strongholds and their surroundings, including archaeological, geographical, historical and onomastic studies, were complemented by an international team (researchers from Poland, Germany, Russia, Serbia, Switzerland and Ukraine).

The results of our investigations shows that Cherven' Towns should be seen not as a border castles with a dominant military function but rather as gateway cities (A.F. Burghardt): an area which connected East-Central and Eastern Europe.

This research included onomastic investigation as well, based on the excellent state of research in Poland. In many cases place names indicate the extent and character of early medieval settlement. According to this general statement, toponyms surrounding the hillforts were analysed to answer the question of whether the strongholds were situated - in relation to the medieval settlement landscapes of that time - in their centre, at their periphery or outside.

6

PLACE NAMES OR COMMUNITY NAMES - AN ATTEMPT TO DECODE ROCK ART SIGNS AS EMBLEM GLYPHS

**Abstract author(s):** Juszczuk, Karolina (University of Warsaw)

**Abstract format:** Oral

The investigation of geographic names is an essential component of archaeological settlement studies and community migration studies. They are an essential part of archaeological interdisciplinary research because they may contain information that is elusive in other ways. However, toponyms need not always be place names encoded by language (linguistic principle). They can also be signs that encode a place name (emblem-glyph) using other principles, such as semasiography. This presentation aims to present an approach to the study of place names/signs by examining individual signs of rock art from northern Venezuela, which I analyze as potential emblems of given societies or places from pre-Columbian times. While this is a new approach to the study of rock art from that region, it has a strong basis in the fact that one of the rock art panels from the Rio Chico region of northern Venezuela was decoded as a topographic map, encoding emblems of specific places. In my presentation, I will present a holistic approach to the study of potential emblems, consisting of archaeological, ethnographical, and historical studies as well as GIS and landscape analyses. I will also present possible interpretations of individual signs as place/community names.

7

FROM BORDER FOREST TO AGRICULTURAL SETTLEMENTS. HIGH MEDIEVAL LANDSCAPE CHANGE BASED ON LINGUISTIC AND ARCHAEOLOGICAL EVIDENCE IN THE HANOVERIAN WENDLAND

**Abstract author(s):** Hardt, Matthias (GWZO) - Schneeweiß, Jens (Exzellenzcluster ROOTS, ZBSA, Stiftung Schleswig-Holsteinische Landesmuseen Schloß Gottorf)

**Abstract format:** Oral

Toponyms especially in border regions form an important source for the reconstruction of historical processes like the high medieval colonization of the 11th-13th centuries AD. Earlier, the Slavic settlement territories were protected by an elaborated system of anthropogenically modified border forests. Written sources, onomastic and archaeological evidence explain how hedges and thorny bushes should prevent unauthorized access. After the 1147 Crusade and Saxon occupation, the Slavic-speaking population between the Elbe and Oder subsequently lost their language and cultural identity. It became a genuine part of a new, German-speaking mixed population characterized by Christianity and measured villages. A planned settling of people from other cultural contexts and languages marked the colonization of the Slavic lands. This played an outstanding role in the implementation of the new lifestyle system, which meant radical change for the local population. While the Slavic material culture disappeared quickly within this process, linguistic evidence in the form of toponyms, personal names and a few enclaves has been preserved. In this context, the "Rundlinge", circular villages that have survived in large number and density in the Wendland west of the Elbe, are being intensively discussed. On the one hand, this particular village form is being associated with Slavs, which is mainly supported by linguistic evidence, on the other hand, they completely lack Slavic material culture. Due to its poor and wet soils, the Hanoverian Wendland is a hostile landscape in many respects. It was therefore a somewhat backward agricultural region for a long time. The interrelation between linguistic and archaeological remains and the surrounding landscape is of crucial interest for the assessment of the Rundling villages and their role in the high medieval colonization process in a border region. Based on this case study, the papers discuss fundamental questions relating to the connection between language and material culture.

8

THE MATERIAL AND SYMBOLIC CONSTRUCTION OF VILLAGE TERRITORIALITY IN NORTHWESTERN IBERIA

**Abstract author(s):** Menendez Blanco, Andres (Università di Genova) - Fernández Fernández, Jesús (University College London)

**Abstract format:** Oral

Present-day village territoriality in the northwest of the Iberian Peninsula results from a process that began in the Early Middle Ages and continues to the present day. Over centuries, a network of small territories was consolidated because of negotiations between the peasant communities and the elites. Within the limits of each geographical unit, all the basic resources necessary for the community were encompassed, and the village's survival depended on their effective governance and exploitation. This is why negotiating these boundaries often resulted in long-lasting disputes for years or centuries. As a result, a set of tangible and intangible elements were generated to consolidate these boundaries against neighboring communities or local powers claims, materializing these conflicts on peasant landscapes. The anthropogenic or natural landmarks of these boundaries were complemented by stories and myths attached to them that justified land ownership by the community orally transmitted over generations. On the other hand, this symbolic universe is a productive source of information complementing the archaeological survey.

In this contribution we will approach these processes considering three themes for discussion: (a) the processes of construction and fixation of boundaries through the combination of physical elements, place names and oral stories, (b) the readings of certain archaeological elements by peasant communities (past and present), and (c) the potential of this oral tradition to complement archaeological prospection.

9	<b>ARCHAEOLOGY AND LANDSCAPE IN CENTRAL SICILY. FROM CASTLE OF TAVI TO “NEW TOWN” OF LEONFORTE</b>
	<b>Abstract author(s):</b> Patti, Daniela (University of Enna)
	<b>Abstract format:</b> Oral
10	The research focused on the framework of feudal ownership of the land, as well as possible reconstructing it by the historical sources available, although not exhaustive and uncertain.
	It’s consist of the descriptiones and the recensiones that, for chronological periods of just over a century, mention the succession of possessions and assets theoretically considered feudal, but really more properly defined as “land lordships” and, in some cases, as territorial lordships, starting from the settlement organization of the eleventh century, marked by numerous fortified structures.
	This kind of research once again showed the importance of toponymy, needed to understand the method of organization and control of land by man who has always seen places, according to the systems with which he organized, inhabited and transformed.
11	The ancient place names of casalia (farmhouse), territoria (land), castra (fortress) and feuda (fief), assignable with certainty by historical and archive documentation, and in some cases (for some areas) integrated archaeological surveys.
	This is the case of the castrum of Tavi, an important example in central Sicily of castle, fortress linked to the rock settlement in the late Byzantine and Islamic Age and located in the heart of large cereal estates, in depopulated areas of the Sicilian countryside, left empty by the disappearance of Norman-era farmhouses, but be revitalized by new settlements ( created from the sixteenth century by Sicilian Aristocracy. The most important example in this landscape is that of Leonforte, built by the prince Nicolò Branciforti to exploit the richness of its waters, as we know also by the different place names linked to issues of the land and to work activities.
A.	<b>TWO LANGUAGES, ONE LANDSCAPE</b>
	<b>Abstract author(s):</b> Klir, Tomas (Charles University, Faculty of Arts, Department of Archaeology) - Jansens, Nicolas (University Heidelberg, Slavisches Institut; Charles University, Faculty of Arts, Department of Archaeology)
	<b>Abstract format:</b> Oral
376	The main aim of this paper is to gain a deeper understanding of the interaction of languages during the colonisation of an unfamiliar landscape and of the dynamics of name-giving in a bilingual society. We will focus on various case studies from the Cheb region as well as neighbouring regions in the Czech Republic and Germany, where Slavic and German(ic) were used simultaneously in the naming of geographical objects in the Early and High Middle Ages. We will employ toponymic evidence of particular interest, written sources and also the archaeological record, which anchor the settlement processes chronologically. On a theoretical level, we will base our work on concepts and systemic models provided by contemporary onomastics, especially on the relational and name-formation models of Rudolf Šrámek, and on the model of toponymic integration and pairs of proper names in language contact areas. We will stress that due to the systemic differences between German(ic) and Slavic and the effects of significant linguistic interference, it is possible to gain both unique and general knowledge about the use of language and name-giving in a historical perspective.
B.	<b>HARNESSING HIGHER-ORDER EVIDENCE IN TOPONOMASTIC DATA AND THE CHALLENGE OF INTERDISCIPLINARITY</b>
	<b>Abstract author(s):</b> Jansens, Nicolas (Heidelberg University; Charles University)
	<b>Abstract format:</b> Oral
A.	To be discussed are new approaches to toponomastic research which seek to move beyond first-order conclusions and extract from existing data new knowledge with broader cultural-historical relevance.
	Among those of particular interest is the systematic analysis of name adaptation processes and their potential for yielding insight into past sociolinguistic contexts. For example, the use of particular adaptation strategies varies over time and space and can thereby indicate degrees of bilingualism as well as changing social norms. Another promising approach – developed by Tomáš Klír – focuses on the geographical extent and social contexts within which settlement or waterbody names are historically documented. Using this data, one attempts to reconstruct the historical use of particular languages within social networks of various scopes.
	A follow-up question is to what extent the findings of such approaches may be of interest for archaeological and further interdisciplinary studies. Here, a particular focus will be placed upon quantitative methods with the use of GIS software for comparative geospatial and statistical analysis of toponomastic and archaeological data. Ultimately, the methods under review here should be regarded as complementary to more traditional qualitative research, without whose data higher order (digital) analyses would not be possible.
A.	<b>THE POWER OF ROMAN PLACE NAMES IN SOUTH HISPANIA</b>
	<b>Abstract author(s):</b> Espana-Chamorro, Sergio (Universidad Complutense de Madrid; Institut Ausonius - UMR 5607, Bordeaux)
	<b>Abstract format:</b> Poster
A.	Τόπος- νόμος is literally a name of a place, a geographical point. Toponymy reveals the world view of a society with multiple cultural nuances and connotations. We can obtain huge amounts of data by examining them: perception of nature, language, ethnography... The Romans also included juridical and political information in their city names. We can advert their role in the Roman world (as a municipium, colonia, civitas libera...) and sometimes the time in which they were promoted (especially with cognomina such as

lulia, Augusta, Flavia...). In this paper, I will examine toponymy as an element of power during the Late Republic and the Early Roman Empire in South Hispania. The use of new foundations related with personal names (i.e. Brutobriga or Metellinum), the use of some specific adjectives in the coloniae (Gemina, Firma, Romula, Patricia) and the political process of land management in some specific areas can draw a map of power during this period and it reveals the different strategies of conquest used along the territory (i.e. erasing names, creating hybrid names, imposing new cities with Latin names...).

## B. HINTS FOR NATURAL AND ANTHROPIC LANDSCAPES IN CORSICA ISLAND. TOPONYMIC ISSUES IN DIALOGUE WITH WRITTEN SOURCES AND ARCHAEOLOGICAL EVIDENCE

**Abstract author(s):** Piccardi, Eliana (Independent researcher)

**Abstract format:** Poster

The diachronic screening of the toponymic resources in Corsica, crossed over by written sources and archaeological evidence offers a multistratified landscape where human presence and activities appear quite significant for the island although not always chronologically easy to be detected.

Glottology may explore certain sites names recalling possible ancient Ligurian (in -sk\* - : Uccinasca, Popolasca) and Etruscan roots (Rapale), while the short Ancient Greek presence, attested in ancient sources, seems not detected beyond the Phocceans’ Alalia colony.

In Corsica, as well as in the ancient Liguria in the same Tyrrhenian area, the most interesting crossing over among toponyms, eventual archaeological reminds and anthropic presence in the landscape is undoubtedly linked to site-names often recalling high and sheltered dwellings, throughout the various ages: Castellare, Castellacciu, I Casteddi, Castello and the several site-name of Castellu di..., A Torra; many sites have given evidence of the human presence from the Prehistoric Age to the Middle Age and onwards on (e.g. Tavera).

Corsica toponyms may carry witness of ancient heritages both about well-known archeological areas or monuments of various ages, and about remote heritage described or even culturally ‘perceived’ and transmitted by the inhabitants: e.g., about the prehistoric menhir-statues (Stantari, Scomunicatu) but especially about Roman Period evidence (Mariana; Taverna, Bagni, Caldanica, Musuleu, Etang de Diana, Capu a L’Altare).

Later, the Christian religion has left a wide sampling of toponomies and evidence, from Early Christian reminds and faith traditions to the Middle Age ones (e.g. Sant’Appianu, La Canonica, San Florenzu and so on).

Beyond the widespread toponyms depicting the main morphologic markers (orographic and hydrographic ones e.g. Monte Bughju; Grotta Piana; Fium’Orbu, Foce di Tanghiccìa, Fangu), there is a strict connection with the exploitation of the land and aquatic resources throughout the centuries (Castagniccia, Carbonacce, Ostriconi, Saleccia, Anguillaghja), and sometimes the mining ones (Argentella).

## EXPANDING HORIZONS: DECOLONISATION, CONTESTED OWNERSHIP OF ARCHAEOLOGICAL MATERIAL, AND THE 1970 UNESCO CONVENTION ON CULTURAL PROPERTY

**Theme:** 3. The new normality of heritage management and museums in post-Covid times

**Organisers:** Godfrey, Evelyn (Uffington Heritage Watch) - Moedlinger, Marianne (University of Genoa) - Joosten, Ineke (Cultural Heritage Agency of The Netherlands)

**Format:** Round table

The collection of antiquities can be seen in the light of the decolonisation movement to represent a Western “Cultural Horizon”. This was characterised by the idolisation of Classical Greek and Roman material culture, including architectural styles, as reflected in the façades of many museums across the world. The association with ancient empires was explicit validation of British, European and American imperialist activities in the 18th to 20th centuries.

As we leave behind the ‘old normal’, what are the specific actions and policies that we as archaeologists need to be pursuing, in order to achieve an equitable settlement in terms of both the ownership of cultural heritage and the expression of the archaeological and historical narrative?

In this Roundtable session of the EAA Community on the Illicit Trade in Cultural Material, we will examine the relevance, limitations, and potential for revision of national laws based on the UNESCO 1970 “Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property”.

We invite members to share experience of how the 1970 Convention is implemented in their country, and the intersection with decolonisation.

Questions for discussants:

- How are ‘decolonisation’, ‘restitution’, ‘repatriation’ defined in practice?
- The 1970 Convention is limited to archaeology “specifically designated” by each State as important, or traded ‘illicitly’. Is the “designation” requirement too onerous?
- Regarding ‘illicit’ trade, how do we treat material acquired legally, but when the local people had no power to object?
- How can we promote local stewardship/public ownership of archaeology in countries that allow private collecting and

- exploitation of the archaeological record, e.g. through metal detecting?
- Should all trade in archaeological and ethnographic material more than one hundred years old be banned worldwide, similar to the proposed global ban on trading in wildlife and ivory?

377 **A WORLD OF CLAY II: FROM FRAGMENTS TO SOCIETIES**

**Theme:** 6. Material culture studies and societies

**Organisers:** Kroon, Erik (Leiden University, Faculty of Archaeology) - Delvoye, Adrien - Debels, Pauline (University of Geneva, Department of Genetics and Evolution) - Arntz, Monique (Cambridge University, Department of Archaeology) - Jean, Mathilde (Université Paris 1 Panthéon-Sorbonne)

**Format:** Regular session

Archaeologists have ever more tools at their disposal to study clay materials (vessels and otherwise) and past societies. For ceramics in particular, interest in chaînes opératoires has recently surged, and concepts such as use-life, craft, and entanglement provide new analytical angles onto past societies. In parallel, the third science revolution in archaeology has given new impetus to studies of mobility, kinship, social transformations, and long-term cultural dynamics.

With the wealth of new analytical tools and concepts comes the need for fundamental reflections on the methods, data, and concepts which aid us in reconstructing past societies through the lens of ceramics. Disciplines such as anthropology, history, and philosophy are key conversation partners when interpreting archaeological ceramics, and understanding the fragilities of our interpretations. Reinforcing the dialogue with these disciplines is vital, especially as the archaeological toolbox continues to expand.

In this session, we want to reflect on the methodologies, questions, and research themes in contemporary ceramic analysis. How can ceramics contribute to questions about social transformations, mobility, entanglement, cultural dynamics, and identity? We invite archaeologists, ethno-archaeologists, anthropologists, and other scholars who work with clay materials from all regions and periods to partake in a multidisciplinary dialogue on social transformations and cultural dynamics through the lens of clay materials. We wish to address such questions as:

1. How do manufacturing traditions and consumption habits reflect the sociality, mobility, and identity of human groups?
2. How can studies of crafting practices and creativity in ceramics contribute to burgeoning fields such as cognitive sciences and the history of knowledge?
3. What are future directions for the analysis of clay materials on a practical and theoretical level, especially in the age of polymers and metal?

**ABSTRACTS:**

1 **SOCIAL CLAYS: REVEALING PAST IDENTITIES AND TRANSFORMATIONS THROUGH CERAMIC ARCHAEOMETRY**

**Abstract author(s):** Gates St-Pierre, Christian - Beaulieu, Guyane - Girard, Jean-Paul (Université de Montréal)

**Abstract format:** Oral

During the second half of the 20th century, the analytical focus of North American archaeologists studying Indigenous ceramic collections underwent a major, yet gradual shift from typological and stylistic to technological analyses, concurrently with the continuous development of archaeometry which is now prevalent in ceramic studies. The two approaches are not incompatible however, and can be used in conjunction to reach a more holistic perspective and to address a variety of research questions, especially those pertaining to the social dimensions of ancient populations. Among such questions are the transformation of stylistic and technological styles through time, and the social significance of these transformations in terms of knowledge transmission processes and cultural identity. After summarizing the historical and conceptual background underlying ceramic analyses in Northeastern North America, two recent case studies from that cultural area that use a computed tomography analysis of Indigenous ceramic collections will serve to illustrate our point.

2 **TOWARDS MAKING SENSE OF MIGRATIONAL MOSAICS: OPERATIONALISING A NETWORK APPROACH TO TECHNOLOGY FOR THE HISTORY OF KNOWLEDGE**

**Abstract author(s):** Kroon, Erik - Djakovic, Igor (Leiden University, Faculty of Archaeology)

**Abstract format:** Oral

5,000 years ago a massive migration fundamentally changed Europe as steppe groups progressively displaced indigenous populations, leaving distinct and novel material culture throughout Europe. Around 40,000 years earlier, a massive migration fundamentally changed Europe as groups of Homo sapiens progressively displaced indigenous Neanderthal populations, leaving distinct and novel material culture throughout Europe. Does history repeat so neatly?

The analogous conceptualisation of these two events, and many migration events like them, are due to the similar questions archaeologists ask about migrations. These questions focus on the ‘beginnings’ and ‘ends’ of groups (i.e. archaeological cultures) which

result from our classifications of artefacts, genomes, styles, etc. Not only is the reification of these classifications problematic, but migration events themselves also invariably turn out to be complex mosaics on closer study.

Our proposition here is to de-center classifications in studies of past migrations, and to instead take the perspective of a history of knowledge. We argue for the use of systematic, empirically-grounded analyses to reconstruct patterns in accumulation and variation of technical knowledge. These patterns are highly informative for understanding mechanisms of learning and knowledge transmission across spatio-temporal landscapes.

To achieve this, we operationalise a network approach for lithic and ceramic artefact production as a means of comparing and conceptualising technological processes. Using case studies of ceramic assemblages from the Corded Ware transition and lithic assemblages from the Middle to Upper Palaeolithic transition in western Europe, we demonstrate the broad applicability of a history of knowledge for archaeological migration events.

3 **AN INFORMATION THEORETIC APPROACH TO MYCENAEAN POTTERY DATASETS**

**Abstract author(s):** Rivers, Ray (Imperial College London) - Gheorghide, Paula (University of Toronto) - Price, Henry (Imperial College London) - Vasiliauskaite, Vaiva (ETH Zurich) - Evans, Tim (Imperial College London)

**Abstract format:** Oral

Understanding the relationship between artefacts and the societies that produced them is difficult. This understanding is dependent on methods of classification, curation, in addition to the usual problems of preservation, fragmentation and incomplete data. It has long been proposed that diachronic change in the nature of assemblage composition can reflect societal change. Pottery lends itself naturally to such an analysis because of the precision in which it can be quantified. This has been pursued by several authors (e.g. see [1,2]) using the diversity of the assemblages with regard to key archaeological markers to monitor societal change.

In this talk we follow this idea by exploring the changes in the diversity of a 13,700+ ceramic data set from five Cretan deposition sites over the Late Bronze Age period Late Minoan II - III B collected by one of us (PG).

Diversity is essentially a measure of how many effective categories we need to describe the different assemblages. We adopt a more general information-theoretic approach to diversity than the authors of [1,2], borrowing from ideas in ecology. Unlike for ecological data sets, archaeological assemblage size does not reflect the size of sites from which they originate. This simplifies the analysis and leads to well-defined multi-site diversities that permit diachronic site comparisons.

For all the seemingly large size of our data set, the bulk corresponds to ceramics that were produced and consumed locally, with a smaller set of ceramics produced elsewhere on Crete. An even smaller set consist of ceramics imported from outside Crete. In this paper we look at the differences reflected in these datasets insofar as the statistics are good enough to permit us to do so.

4 **PERIOD-, SITE- OR GEOLOGY-SPECIFIC? RAW MATERIAL SELECTION IN THE 3RD-2ND MILLENNIUM BC POTTERY PRODUCTION OF THE UPPER RHÔNE VALLEY (SWITZERLAND)**

**Abstract author(s):** Carloni, Delia (Laboratory of Prehistoric Archaeology and Anthropology, Department F.-A. Forel for Environmental and Aquatic Sciences, University of Geneva) - Šegvić, Branimir (Department of Geosciences, Texas Tech University) - Sartori, Mario (Department of Earth Sciences, University of Geneva) - Zanoni, Giovanni (Department of Geosciences, Texas Tech University) - Besse, Marie (Laboratory of Prehistoric Archaeology and Anthropology, Department F.-A. Forel for Environmental and Aquatic Sciences, University of Geneva)

**Abstract format:** Oral

A variety of spectroscopic and microscopic techniques have been widely established in the investigation of the raw material procurement, selection, and use in the archaeological pottery production. While acquisition of analytical data from the raw material is relatively straightforward its interpretation in the context of the local archaeology and background geology may be somewhat challenging. This paper highlights the limitations one may face while interpreting archaeometric data when relevant contextual information is scarce or non-existent.

This study reports on raw material choices and paste preparation recipes inferred for the 3rd and 2nd millennium BC pottery production in the Upper Rhône Valley. The geological setting of this Alpine valley is rather complex since the outcrops of metamorphic, (meta)sedimentary, and intrusive rocks are found throughout the region and Quaternary glaciation and semi-arid climatic conditions hampered a largescale formation of clay deposits. The Final Neolithic, Bell Beaker period, and Early Bronze Age (3300-1600 BC) settlement sites are widely distributed across the valley, which forces one to consider the distinct local geological setting while investigating the implications of compositional variations. In addition, certain sites have been widely excavated over several years while others were made known through the test trench only. This leaves us with major differences in the amount and quality of information on stratigraphy, human-related structures, and chronological attributions of the findings. Complexity caused by non-uniform geology and site documentation makes an illustrative example of the difficulties encountered by archaeologists when reconstructing the past manufacturing traditions and reflecting on the underlying long-term historical and cultural dynamics from a regional, synchronic, and diachronic perspective.

5 **HIDDEN SOCIAL IDENTITY? NEOLITHIC POTTERY TRADITIONS AND RADIOCARBON CHRONOLOGY**  
**Abstract author(s):** Kvetina, Petr - Hrnčíř, Václav (AU - Institute of Archaeology of the Academy of Sciences of the Czech Republic, Praha) - Trampota, František (Department of Archaeology and Museology, Faculty of Arts, Masaryk University, Brno)  
**Abstract format:** Oral

The aim of the paper is to interpret social identity hidden behind the stylistic variability of the Neolithic pottery in the territories of Czechia and northern Lower Austria (ca 5400–3300 BC). The changes and variability of the manufacturing pottery traditions are traditionally viewed as fundamental indicators of (i) archaeological cultures, which are then further divided into chronological (ii) stages and (iii) phases. By comparing the typo-chronological development of pottery and modelling the corresponding radiocarbon dates, we are testing these three levels in sense of relation to other cultural parameters (social identity, regional variability, distribution zones of pottery producers). Modelling of radiocarbon horizons indicates that changes in the original material culture do not necessarily occur on a time axis. While it is true that archaeological cultures have proven to be the robust materialisation of primarily chronological trends valid in larger geographic areas, at the level of more detailed pottery groups, development can be manifested in other ways (regionally, socially or in a way that is difficult to interpret).

6 **OBSERVING THE RELATIONSHIP BETWEEN FUNERARY AND DOMESTIC CONTEXTS USING POTTERY TECHNOLOGY: THE UPPER RHÔNE VALLEY DURING LATE PREHISTORY**  
**Abstract author(s):** Derenne, Eve (Laboratoire d'archéologie préhistorique et anthropologie, Université de Genève) - Ard, Vincent (UMR 5608 TRACES, Université Toulouse Jean Jaurès) - Besse, Marie (Laboratoire d'archéologie préhistorique et anthropologie, Université de Genève)  
**Abstract format:** Oral

Pottery technology analysis has proven to be an effective tool in revealing the human groups behind ceramic assemblages. It allows for the identification of communities of practices and the observation of evolution in transmission processes. The fact that this type of study is feasible on a large geographic scale constitutes another element recommending it to archaeologists.

However, ethnography has shown that such studies yield better results when focused on a smaller chronological range, as changes in transmission processes can happen fast, in a single generation or less. When working on prehistoric periods, attaining such a small time frame is almost impossible, with phases often exceeding 200 years in duration. Nonetheless, we disagree with the implication that technological analyses can therefore only be applied to sites with short occupation phases, such as pile dwellings.

In this presentation, we plan to discuss how the shortcomings inherent to non-wetland prehistoric assemblages can be mitigated in order to benefit from the important data brought by technological analyses. We wish to demonstrate that prehistorians can still approach questions of social transformations, entanglements, and mobility by (1) enlarging their chronological scale to include previous and succeeding phases and (2) considering funerary and domestic contexts in relation to each other. For example, this could mean comparing the selection of ceramics for funerary assemblages with what we find in domestic sites from the same region. One key element of this would be the identification of ceramic productions from different communities associated with the same necropolis. As a case study, we will present the results obtained by the analysis of ceramics from the Upper Rhône valley in South-western Switzerland between 3300 and 1600 cal BC. This study manages to link the pottery assemblages from small settlement sites to the megalithic necropolis of Sion 'Petit-Chasseur'.

7 **DISCUSSING SOCIAL DYNAMICS OF A POTTERY WORKSHOP: EVIDENCE FROM THE MIDDLE NEOLITHIC SITE IMVROU PIGADI, GREECE**  
**Abstract author(s):** Saridakí, Niki (University of Crete) - Kyriáki, Nina (Ephorate of Paleoanthropology and Speleology) - Kalogiropoulou, Evita (University of Crete)  
**Abstract format:** Oral

Pottery has been a powerful tool for the understanding of human past that inscribes social dynamics, community practices, habits and customs. Its manufacturing traditions reflect regional networks of social histories and reveal how a social identity group was linked with certain characteristics. In Neolithic Greece, only a small number of production centers are known leaving open questions about the social role of pottery production and distribution.

In this paper we present the case of a Middle Neolithic pottery workshop at the tell site Imvrou Pigadi, located at the south-western edge of the Thessalian plain in Greece. This exceptional find brought to light evidence of pottery production at a designated and organized pottery workshop and enriched our views on Neolithic pottery manufacturing practices in the region. The remains show how a pottery workshop was organized, following temporal social requests in producing pottery for daily and social use. The paper presents the pottery types, based on morphological, decorative and technological styles and traditions, shedding light on the operation of the pottery workshop and its production. Based on the evidence of pottery, we can approach social dynamics and community practices developed in the region during the Middle Neolithic period. How many pottery forms and decorative styles were produced in the workshop? Can we identify certain daily and social practices or traditions embedded in and reflected by the pottery production? Does the pottery workshop at Imvrou Pigadi serves for a single site or is it part of a wider community network? Does pottery production in Thessaly during the Middle Neolithic shows evidence of social transformation? This research is conducted

in the framework of BONDS - 'Beyond Oikos: Outdoor spaces, daily life and sociality in Neolithic Greece' Project (Number: 00229), funded by H.F.R.I.

8 **SHAPE STANDARDIZATION, CERAMIC SPECIALIZATION AND ITS IMPLICATION TO SOCIAL COMPLEXITY: A CASE STUDY OF NEOLITHIC POTTERY FROM TAOSI SITE, CHINA**  
**Abstract author(s):** Bai, Yang (Kyushu University)  
**Abstract format:** Oral

Ceramic specialization is often linked to implications related to social complexity. However, to simply link ceramic specialization and particular forms of social organization could be problematic due to the cultural diversity. As such, this paper aims to clarify the specific connection between ceramic specialization and social complexity in a Chinese Neolithic context. The author has chosen the cooking vessels excavated from the Taosi site (2300-1900BC), a proto-urban settlement of the Chinese Late Neolithic period, to investigate the dynamic change in ceramic specialization and its possible link to social complexity. This study has investigated pottery standardization by analyzing shape variables with geometric morphometrics analysis, one of the quantitative approaches to studying ceramic specialization. The study finds that the morphological variation of the cooking vessels, which was considerably large in the early period decreased in the middle and late periods, showing a trend toward standardization. It has also been revealed that consumption pattern also changed from the intra-community in the early period to the cross-community exchange in the middle and late periods.

The result shows that ceramic production became steadily specialized at the Taosi, but the tempo of pottery production specialization differed between the residential communities forming the proto-urban settlement. In terms of the elite's intervention in ceramic production, the middle period witnessed intensive control over specialized production units by the elite and the late period witnessed the disappearance of such control as the extant political structure appears to have collapsed. This historical process suggests that the elite controlled the specialized ceramic production for the purpose of enhancing their political authority. Interestingly, the collapse of a political authority did not affect the progression of the specialization of ceramic production.

9 **POTSHERD TOOLS IN THE SOCIAL ORGANISATION OF EARLY NEOLITHIC SOCIETIES IN SOUTH-EASTERN/CENTRAL EUROPE: CONTRIBUTIONS FROM THE ANTHROPOLOGY OF TECHNIQUES**  
**Abstract author(s):** Vindrola Padros, Bruno (Institute of Archaeology, University College London) - Vieugué, Julien (Institute of Archaeology and Ethnology, Paris Nanterre University, French National Centre for Scientific Research - CNRS)  
**Abstract format:** Oral

It is now becoming widely recognised that rather than the simple arrival of a 'technological package' the Neolithisation of Europe occurred in a variety of forms across the continent. Yet, despite this recognition, there is still very little known about the transformations of technologies undergone at a local level, as well as the bodily gestures involved in their use. This is certainly the case with the reuse of pottery, even though sherd tools and other similar objects became widespread in the Early Neolithic of south-eastern and central Europe. This paper aims to show how the reuse of broken pottery formed an important part in shaping social food (such as cooking) and craft activities (like hide processing and pottery manufacturing), and how some of the gestures involved in their use changed in these areas of the European continent. By incorporating an approach from the anthropology of techniques, we study these long-forsaken artefacts from their stages of procurement, shaping and use at various Early Neolithic Karanovo, Körös-Criş, and Linearbandkeramik sites. Use-wear analysis of potsherds combining microscopic and microphotogrammetry techniques were particularly developed to identify the gestures involved in the use of these artefacts, as well as determine the worked materials. Our study clearly shows the potsherds reused as tools were collected after the discard of broken ceramic vessels. While some of these sherds were reshaped before use, others were employed in an ad hoc way. A range of sherd objects like hide scrapers, pottery scrapers and smoothers, spindle whorls, and potentially heat-retainers were identified, showing the large range of uses given to sherds by the Earliest Neolithic societies in Europe.

10 **EXPERIMENTAL MODELING OF ASBESTOS- AND ORGANIC-TEMPERED VESSELS FROM THE LATE NEOLITHIC OF EASTERN FINNOSCANDIA**  
**Abstract author(s):** Kholkina, Margarita - Muravev, Roman (Saint-Petersburg State University; Peter the Great Museum of Anthropology and Ethnography - Kunstkamera) - Zhulnikov, Aleksander (Petrozavodsk State University)  
**Abstract format:** Oral

A tradition of making asbestos-tempered pottery first appears in Lake Saimaa region (modern Finland) in the 5th mil. BC. Since 3600 BC area of asbestos-tempered pottery distribution gradually increased and finally covered almost all of Fennoscandia from Southern Norway in the West, where it exists up to the first centuries AD, till the White Sea region in the East. Tempering clay paste with asbestos fibers became so wide-spread at the end of the Neolithic that pieces of asbestos began to be transported hundreds of kilometers away from its original deposits to the territories where no asbestos was found in natural occurrence. All these facts allow us speak of asbestos-tempered pottery as a special phenomenon. Studying this phenomenon provides us an opportunity to reconstruct a wide network of contacts between asbestos-bearing core regions and asbestos-missing periphery, as well as to discuss issues of a pottery tradition itself: how it originated, transformed and spread to such a vast territory in the Neolithic and later periods. Studying this phenomenon, we can't avoid the question: why was asbestos so popular as a temper for making pot-

11 tery? Could the reason lie in its technological advantages against other contemporarily used materials, or is this advantage perhaps non-functional, socio-cultural or even sacred?

To find the answer to these questions, we conducted a large-scale experiment in which we modeled over a hundred of standardized vessels with the temper of asbestos, feather and crushed granite-gneisses in various combinations and concentrations close to ones known from archeological data. In our paper we'll show the observations we've made by comparing the qualities of these tempers in modeling, firing and using experimental vessels.

The study was performed within the project “Phenomenon of Asbestos Ware in pottery traditions of Eastern Europe: making and use technology, structure of interregional contacts”, Russian Science Foundation, #19-18-00375.

**AN INKA HAUKAYPATA IN EL SHINCAL DE QUIMIVIL (ARGENTINA): CERAMIC STUDIES TO UNDERSTAND PUBLIC SOCIAL PRACTICES IN THE KOLLASUYU**

**Abstract author(s):** Scaro, Agustina (Institute of Andean Ecorregions - CONICET-UNJu; Institute of Geology and Mining - UNJu) - Couso, María (División Arqueología, Facultad de Ciencias Naturales y Museo - UNLP) - Moralejo, Reinaldo (División Arqueología, Facultad de Ciencias Naturales y Museo - UNLP; CONICET)

**Abstract format:** Oral

The Inca Empire conquered a large part of South America with a central policy that sought to materially introduce conquered peoples into the Imperial Landscape through urbanisation, building administrative architectural elements throughout the Empire. Urban political-ceremonial settlements were centred around the plaza or haukaypata, where core activities for social interaction were carried out within the imperial cosmovision. El Shincal de Quimivil (Northwestern Argentina) was planned following these Inca models, becoming one of the main regional political-ceremonial centres in a landscape of intense dynamics. Among its most outstanding features are a 30,625 m2 plaza and a large number of administrative and housing buildings.

To comprehend public social practices that took place in El Shincal plaza, considering social, political, and ideological aspects of Inca administration, 320 sherds were analysed, emphasising a morpho-decorative analysis within stylistic studies. The study revealed the predominance of Provincial Inca pottery (32.5%), while other local styles are very scarce. The presence of Inca Cuzqueño sherds (4.95%) is relevant as they correspond to vessels imported from Cuzco and are very rare in provincial administrative contexts. Their presence in El Shincal reinforces its importance as an imperial centre. The high incidence of aryballos (30.03%), directly associated with the consumption of a highly valued maize beer, indicates that public events were held at the plaza where it was shared alongside large amounts of food (as indicated by cooking vessels with and without soot).

The ceramic analysis provides material evidence about public events sponsored by the imperial administration in the plaza, where reciprocity and redistribution of goods between the Empire and local peoples were at stake. The high proportion of Provincial Inca vessels would indicate that large quantities of food and drink were provided by the administration. This evidence is consistent with the descriptions made by Spaniards chroniclers about haukaypata.

**TRACING EXCHANGE PATTERNS — THE CONTRIBUTION OF TECHNOLOGICAL APPROACHES TO THE IDENTIFICATION OF POTTERY TRADITIONS**

**Abstract author(s):** Verdelle, Cécile (Gerda Henkel Stiftung; UMR 7041 ArScAn) - Vilain, Sarah (Marie Skłodowska-Curie Fellow)

**Abstract format:** Oral

Since the 90's, the development of technological analyses within ceramic studies offers the opportunity to complement traditional approaches. Indeed, the manufacturing process has since become an important criterion in the identification of pottery traditions. The diffusion of cultural traits as well as the transmission of the potters' knowledge are now considered as significant signs of social contacts. Over time, the development of exchange networks favoured interactions between craftsmen, resulting in significant modifications in ceramic productions.

Through two case studies, this paper will show how the contribution of technological analyses, combined with typological studies, highlight intercultural interactions and provide new data concerning the understanding of trading connections.

During the 3rd millennium BCE, the intensification of the Mesopotamian exchange network is observable though the reduction of the variety of shapes in pottery assemblages. However, technical studies show that ceramics are still mainly produced locally. Based on a comparative study of specific pottery types from two sites of north-east Mesopotamia, this part will question the standardisation phenomenon and its meaning in the Mesopotamian social organisation.

During the 2nd millennium BCE, Levantine harbours play a crucial role in the circulation of commodities within the Eastern Mediterranean. As a result, Levantine populations are exposed to foreign containers of exogenic shapes, motifs and technics. Soon, imitations as well as new entangled ceramic productions emerge alongside local pottery shapes. Through selected examples, this part will explore the concepts of “local” and “foreign” and discuss how technological studies can be used to pinpoint features related to distinct practices and craft skills.

Ultimately, both case studies developed in this paper put forward how the combination of technological and typological approaches offer new perspectives on pottery traditions and turn out to be useful tools to trace exchange patterns and reassess their overall evolution.

13 **ADAPTATION AND TRANSFORMATION OF THE CERAMIC MANUFACTURE FOR SUGAR PRODUCTION IN MEDIEVAL EUROPE**

**Abstract author(s):** Montesana, Roberta - Buxeda i Garrigòs, Jaume (Cultura Material i Arqueometria UB - ARQUB, GRACPE, Dept. d'Història i Arqueologia, Facultat de Geografia i Història, Universitat de Barcelona) - Kilikoglou, Vasillis - Hein, Anno (Institute of Nanoscience and Nanotechnology, N.C.S.R. “Demokritos”) - Madrid i Fernández, Marisol (Cultura Material i Arqueometria UB - ARQUB, GRACPE, Dept. d'Història i Arqueologia, Facultat de Geografia i Història, Universitat de Barcelona)

**Abstract format:** Oral

Sugar production and consumption followed the Islamic expansion in the western Mediterranean and had a huge impact on European social, cultural and economic development. The introduction of sugar cultivation entailed a degree of knowledge transfer and new technological requirements, such as the manufacture of sugar pots, used for the crystallization of the sugar, which require a specific design, thermal and mechanical properties. Potters supplied the specific demands of the sugar industry and supported one of the most valuable productions of the Mediterranean in medieval times. However, little was known whether this specific ceramic production was occurring nearby sugar installations or vessels were imported from somewhere else; whether potters were applying their know-how or transformed it to produce such specialised vessels; whether common requirements, standards, for the manufacture of sugar pots were circulating alongside with sugar in the western Mediterranean.

This paper presents part of the results of the Marie Skłodowska-Curie project “SPotEU: Sugar Pot manufacture in Western Europe in the medieval and post-medieval period (11th-16th centuries AD)” which explores sugar pot production and circulation in modern Sicily and Spain. Sugar pots were assessed on morphological, technological and performance points of view aided by instrumental analysis and software modelling. For this presentation, two sugar and pottery production sites of the 15th-16th cent AD are compared, one in Sicily (Himera-Bonfornello) and one in south Spain (Motril). These two contemporary contexts were geographically distant but unified under the same political entity, the Crown of Castile and Aragon, and being part of the western Mediterranean sugar market.

The detailed reconstruction of sugar pots manufacture and circulation allows us to discuss the diverse potters' choices, the manufacture organization and the local adaptation to a common design. As well, this paper will reflect how archaeological science can offer insights on knowledge change and transformation.

14 **“COOKING HISTORY”: SOCIOCULTURAL, TECHNOLOGICAL AND GASTRONOMIC EXCHANGE THROUGH THE CASE STUDY OF THE PUNIC-ROMAN CITY OF CARTEIA (SAN ROQUE, SPAIN)**

**Abstract author(s):** Sánchez Moral, Carmen María (Universidad Autónoma de Madrid)

**Abstract format:** Oral

Communication and trading hubs have always been optimal points to get an insight into cultural contacts and the transmission, exchange and assumption of different cultural and technological features associated with and derived from them. Thus, the main aim of this paper is to address these phenomena of cultural interaction through the analysis of the ceramics found at the Punic and Roman port town of Colonia Libertinorum Carteia (San Roque, Cádiz, Spain). The interest of the exceptional case study of Carteia lays on its geostrategic location as the keystone of the arch of the Bay of Gibraltar. That is, a place between two continents, two seas and two bays.

While this interdisciplinary study will be multifocal and holistic, special attention will be paid to technology and foodways, since gastronomy is an undeniable cross-sectional marker for both short and long-term cultural and identity dynamics. Being fundamental to human existence, food consumption implies a deeper dimension beyond mere subsistence, since it is the result of cultural interpretation and consumers choices. Hence, we will focus on their primary pottery evidence -kitchenware and tableware-, crucial yet silent witnesses of daily culinary practices, although different pottery classes will also be considered. Moreover, this contribution will be organised diachronically to analyse the evolution and variation of social and commercial trends and their impact on local technology -chaîne opératoire, incorporation of exogenous technological features, vessel shapes...- and culinary traditions, as well as the relation -the “dialogue”- between imported ceramics and local productions during the transition from Late Punic to Roman Republican periods. These aspects prove to be highly enriching in terms of tracking the eventual arrival of new people, given the integration of Carteia in the Roman Empire as a colony - one of the first colonies with Latin rights outside the Italian Peninsula.

A. **A NEW DEEP LEARNING CLASSIFICATION TOOL FOR CERAMIC DECORATION: A CASE STUDY FOR THE BELL-BEAKER POTTERY**

**Abstract author(s):** Paulos-Bravo, Rodrigo (Complutense University of Madrid) - Cifuentes-Alcobendas, Gabriel (Institute of Evolution in Africa; University of York)

**Abstract format:** Poster

Bell Beaker could be considered one of the first pan-European phenomena in Prehistory. However, this apparent homogeneity in ceramic shapes underlies a great heterogeneity in the styles and decoration techniques. Among these styles, one of the most common in southern Europe is the known as ‘incision-style’ and its regional variations. Nevertheless, in the recent years, some authors have questioned the nature of these incisions, arguing that the decoration was indeed made by impression techniques. In this way, a new term has been coined to refer to these styles that are still on discussion: ‘incision-impression style’.

Recently, Artificial Intelligence methods based on Deep Learning and Computer Vision algorithms have been used to successfully differentiate and classify very distinct types of taphonomic marks. In that case, the marks being examined were almost identical to the naked eye, but the high computational power of these analyses was able to highlight features that went unnoticed by scholars until that moment. The success showed by these methods in the correct identification of structurally similar marks leads us to believe that they can also be applied to Bell Beaker decorations, probably yielding more accurate and replicable results than those that have been exposed to this moment.

The interest of knowing the techniques used for the decorations does not only relies on satisfying a research curiosity, but it can also allow us to get closer to the idiosyncrasy of the people who made them, as well as to generate new questions. Did these people use the same techniques in all the regional variants? Are certain techniques linked to any particular region? Were all the variations made with the same tool type? This work attempts to show the potential of Deep Learning for understanding the Bell Beaker phenomenon and the societies that made and used it.

B. **MANUFACTURING TRADITION IN A WORLD OF IMITATION AND ACCULTURATION: A CASE OF CULTURAL TRANSFORMATION THROUGH CERAMIC ANALYSES**

**Abstract author(s):** Moreno Megias, Violeta (Instituto del Patrimonio Cultural de España; Universidad de Sevilla)

**Abstract format:** Poster

In the analysis of the process of “Romanisation” of southwest Hispania, the establishment of productive initiatives has become one of the main indicators of the dynamics of social transformation. The beginning of the production of eminently Roman pottery forms is undoubtedly considered a factor of “cultural conquest” and economic domination. However, in few cases has the study of this productive renewal of the craft sector considered other internal aspects of the artefacts themselves: despite having an apparently canonical Roman morphology and undoubtedly being made with local materials, the methods of production may reveal important differences in the craft tradition of the people that modelled the objects. These are subtle differences since the potter’s wheel was well established and mastered and the technical skills of the craftsmen were undoubtedly capable of adapting to Roman standards; but archaeometric analysis can help to distinguish between those elements that remain linked to tradition despite the imposition of new formal trends and those productions that appear to be imposed from outside in the manner of a production ‘franchise’.

379 **THE INTERACTION BETWEEN NOMADISM AND SEDENTISM: AN APPROACH THROUGH RELIGIOUS PRACTICES AND BELIEFS**

**Theme:** 4. Globalisation and archaeology

**Organisers:** Ethier, Jonathan (Institute of Pre- and Protohistoric Archaeology, CAU Kiel) - Broglia de Moura, Samara (Centre de recherche sur les civilisations de l’Asie orientale (CRCAO, UMR 8155); Archéologies et Sciences de l’Antiquité (ArScAn, UMR 7041); École Pratique des Hautes Études - EPHE/PSL, Paris)

**Format:** Regular session

Throughout history, the continuum between nomadism and sedentism encapsulates humans’ relations in constant negotiation. Belief systems and religious practices played an important role at the junction of these two lifestyles, engaging shared and opposed sacred values at each interaction. Even though, the structure of belief systems and its physical translation have been central in the archaeological narrative, a thick veil still persists on its fundamental participation in the mediation between nomadic and settled lifeways.

This session seeks to explore the role of religion, its practices and institutions, in mobile contexts (nomadism, pilgrimage, etc.) and the establishment of more permanent sites. We will discuss the influence of religion on the formation of cities and urban life and its significance on the (re-)formation of encultured landscapes via pilgrimage routes, settlements, monuments, and other ritual nodes dotting the lands. Thereby, we will reflect on the religious impact on the concepts of mobility and permanency, through an archaeological, historical, and ethnographical lens.

Following a global and asynchronous perspective, the aims of the session are a) to approach this phenomenon via different angles, from material culture to sacred architecture to its inscription into the physical and cultural landscapes, and b) to explore the place of the sacred and the profane in this negotiation across different fields, such as political, economic, cultural, or religious. We invite contributions from across the disciplinary spectrum, ranging from anthropological and socio-economic approaches to historical foci, on one of the following themes: 1- religion, urbanism, and nomads; 2- sacred monumentality from pilgrimage to lieux de mémoire; and 3- encultured landscapes: a hierophanic appropriation.

**ABSTRACTS:**

1 **WHAT IS THE IMPACT OF RELIGION ON NOMAD-SEDENTARY INTERRELATIONS IN ROMAN AND BYZANTINE NORTH AFRICA (1ST TO 6TH C. CE)?**

**Abstract author(s):** Syrbe, Daniel (FernUniversität in Hagen)

**Abstract format:** Oral

The close interrelation of nomadic and sedentary populations is a characteristic feature of the cultural history of North Africa in antiquity. Urban populations and mobile pastoralists were linked in various ways, economically, socially and of course by religious ties, as for example widespread dedications for indigenous North African gods such as the dii Mauri demonstrate. In late antiquity, Christianity as a monotheist religion had the potential to unite and integrate social communities by a shared religion, but also to split local populations by claims of orthodoxy or accusations of heresy.

Tracing religious interrelations between nomadic and sedentary populations in North Africa can build on different types of sources and faces several interesting methodological problems. Literary sources speaking about the religion of nomadic societies were exclusively written by sedentary writers, which normally came from an urban environment that shaped their world view on cultural difference. Texts written by those authors tend to use religion as a tool to describe the cultural “otherness” of the nomads and, therefore, present a strongly biased picture of religious systems in the nomadic sphere. Epigraphic and archaeological materials, in contrast, indicate a much closer integration of indigenous North African cults into the sedentary urban sphere, but raise questions of how to identify nomads as bearers of a cult or how to differentiate between nomadic and non-nomadic indigenous practitioners.

Despite a long tradition of archaeological and historical research on cults and religions of the North African provinces of the Roman empire and the role of indigenous cults going back to pre-Roman traditions, the question of how nomadic populations fit into the picture still has been largely neglected. By drawing on written and material sources, the proposed paper will aim at lining out the role of religion in nomad-sedentary interrelations with a particular focus on methodological questions.

2 **THE RELIGIOUS COMPLEX OF MENOUTHIS: FROM PAGAN ORACLE TO CHRISTIAN HEALING SHRINE**

**Abstract author(s):** Fischer, Tom (Ecole Pratique des Hautes Etudes - PSL; Laboratoire d’Etudes sur les Monothéismes - CNRS, UMR 8584)

**Abstract format:** Oral

In the early 2000s, the underwater archaeological excavations carried out in the bay of Aboukir allowed Franck Goddio and his team to update our knowledge of the Canopic region (East of Alexandria, Egypt). The emplacement of the flooded city of Menouthis, for example, has been clarified. Nowadays forgotten, the temple of this city, dedicated to Isis « truthful » (« ἀλήθεια ») and housing an oracle as well as a place of cure by incubation, was yet known as one of the most famous pilgrimage centers in Roman times, before a competing Christian place of worship opened there in the fifth century CE.

The complex history of this place fits into the well-known practice of the reuse of pagan shrines by Christians. Indeed, despite the conversion of the local population, the temple remained a center of interest. To counter this persistent success, the Christian authorities did not content themselves with destroying idols and building a monastery and a church nearby. They ended up bringing to Menouthis Saint Cyrus and Saint John’s remains, to which were attributed medical miracles. The example of the site of Menouthis, and of its continuum of religious usage, therefore highlights the weight and the force of attraction of a place of pilgrimage in a policy of conversion and land use planning. These are the points this communication aims to clarify and discuss.

3 **THE COMMON GROUND: ISLAM, NOMADS AND URBAN DWELLERS IN MEDIEVAL HORN OF AFRICA**

**Abstract author(s):** de Torres Rodríguez, Jorge (Incipit - Institute of Heritage Sciences)

**Abstract format:** Oral

During the medieval and early modern ages, the Horn of Africa was one of the most active and complex regions in the world, playing a fundamental role in the trade routes that crossed the Red Sea and connected the Mediterranean with the Indian Ocean. The region, under the rule of a score of Muslim states, was home to very diverse groups, including nomadic pastoralists and sedentary villages and towns that acted as nodes in the trading routes to the interior of Africa. This paper analyses the relationships of these two communities with very different lifestyles and cultural, economic and social parameters, and how despite these differences they were able to find common grounds to collaborate and interact.

Probably, the most important of these shared interests was religion. Islam arrived to this part of the Horn of Africa relatively late, but became a strong force to promote a sense of common identity among the inhabitants of the region, even if it had different material expressions in each community. This paper will study the case of Somaliland to analyse the religious spaces of both nomads and urban dwellers (e.g. mosques, graveyards, monasteries, pilgrimage centres), the reminiscences of pre-Islamic religions in the archaeological record and the emergence of a religious landscape throughout the territory, which has survived until today.

4 RELIGION AND URBANISM AS MEANS OF COMMUNICATION BETWEEN NOMAD ELITES AND THEIR SUBJECTS - THE CASE OF MONGOL QARA QORUM

**Abstract author(s):** Rohland, Hendrik (Commission for the Archaeology of Non-European Cultures, DAI)

**Abstract format:** Oral

Between about 1220 and 1260 Qara Qorum was perceived as the capital of the vast Mongol Empire. The city is well known from contemporary written accounts to have been a melting pot. The presence of people of different religions and their places of worship attest to the importance of religious pluralism for the Mongol Empire and its pursuit of universal rule. This was not only a by-product of rapid expansion of the empire but also conscious policy of the Mongol rulers, culminating in the ostentatious staging of religious debates between Buddhist, Christian and Muslim clergymen, presided by the Khan himself. The place of such events were “cities” and residences, that resembled urban centres of sedentary people. They were the stage where the Mongol elite encountered the diverse people and religions of the empire for various transactions. The contribution hypothesizes, that exactly these encounters were an important purpose for the establishment of cities in the nomad context.

Archaeological evidence gathered by the investigations of the Mongolian-German Karakorum-Expedition allows, as a case study, some cautious insight into the development of the eastern Christian community in Qara Qorum. The interpretation suggests, that in the early phases of the empire Christians from Central Asia were directly represented in Qara Qorum. As the political framework shifted from an empire with universal ambitions towards the more China-focused Yuan dynasty, religious practice and its materialization seem to have changed to accommodate to the new conditions. Christian religious symbols were met intermixed with remains seemingly related with a sacrificial cultus. The archaeological record in Qara Qorum thereby seems to mirror the changing relations of rule, religion and urbanism in the eastern part of the Mongol Empire in the 13th and 14th centuries.

5 MONASTERIES IN THE CENTRE OF URBANISATION: PERMANENT SETTLEMENTS IN OUTER MONGOLIA DURING THE PERIOD OF THE MANCHU QING DYNASTY

**Abstract author(s):** Ressel, Christian (Christian-Albrechts-Universität zu Kiel)

**Abstract format:** Oral

Buddhism and the presence of Buddhist temples have a long history among nomadic societies of the Mongolian steppes. Initially rather related to the legitimization of political leadership, Tibetan Buddhism became widespread among the entire population of Mongolia during the second half of the 16th century. After Outer Mongolia was incorporated into the Manchurian Qing Dynasty in 1691, Buddhism was further supported by the imperial court, to reduce the power of the Mongol lay nobility and pacify the population. The number of monasteries increased rapidly, and besides military garrisons, they became focal points of the formation of permanent settlements among the largely nomadic population.

This talk intends to provide a new perspective on the mediation between nomadism and sedentism in Mongolia by approaching monastic settlements as urban nodes. Although many scholars worked on Buddhism and monasteries in Mongolia, little research has been done to analyze monastic settlements as city-like places of interaction between settled and mobile lifestyles. By applying urban anthropological theories, monasteries will not be understood as isolated sites as opposed to a nomadic hinterland, but as specialized nodes of connectivity, communication and exchange.

The presentation focuses on the monastery Baruun Khüree and its surrounding area of the Orkhon Valley. It will point to (1) how the monastery was interrelated with or distinguished from other monasteries and permanent sites within the region, particularly the famous monastery Erdene Zuu, and (2) the dynamics of urbanism that evolved in relation to a monastic node and its institutions. This requires rethinking the dichotomy between nomadic and sedentary lifestyles, usually based on concepts of land-use, with regard to religious practices, administrative duties, and economic interdependencies.

6 SARIDAG: A MONGOLIAN BUDDHIST MONASTERY COMPLEX OF THE 17TH CENTURY

**Abstract author(s):** Chadraabal, Enkhtuul (Ur- und Frühgeschichte, Christian-Albrechts-Universität zu Kiel)

**Abstract format:** Oral

The site is a 17th-century ruin called Saridag Monastery, located about 70 kilometers northeast of Mongolia’s capital Ulaanbaatar in the Saridag Mountains of Khan Khentii, which includes Chinggis Khan’s sacred mountain Burkhan Khaldun.

The complex was built in 1654-1686 by Zanabazar, also known as Öndör Gegeen Zanabazar (1635-1723), the first Jebtsundamba Khutuktu or spiritual head of Buddhism for the Khalkha in Mongolia. Two years after completion, in 1688, the site was destroyed by Galdanboshigt’s army only during warlike clashes between Khalkha Mongols and Oirat Mongols and has not been rebuilt since.

A national research team from the Institutes of History and Ethnology at the Mongolian Academy of Sciences conducted excavations at Saridag Monastery for six years, between 2013-2018. As a result of the excavations, approximately 3,000 clay Buddhas, a Buddha statue cast in copper, ceramic cups, a silver bowl, prayer beads, two helmets, four metal swords of European type, two spearheads, two rifles, two silver coins, an ivory sundial, and as well as numerous architectural findings were found in the northern part of the main temple of Saridag Monastery. With Mongolia being in constant negotiation between a nomadic lifeway and a sedentary one, monastic communities played a central role between both instances. This paper introduces one of the major sites and its place at the negotiation table.

7 EMERGENCE OF NECROPOLISES AND CHANGE OF BURIAL RITES IN THE WESTERN ALPS: ANTHROPOLOGICAL AND CHRONOLOGICAL INVESTIGATIONS OF NEOLITHIC CIST GRAVES

**Abstract author(s):** Steuri, Noah (Department of Prehistory, Institute of Archaeological Sciences, University of Bern) - Milella, Marco - Lösch, Sandra (Department of Physical Anthropology, Institute of Forensic Medicine, University of Bern) - Szidat, Sönke - Hafner, Albert (Department of Prehistory, Institute of Archaeological Sciences, University of Bern; Oeschger Centre for Climate Change Research - OCCR, University of Bern)

**Abstract format:** Oral

Only few Mesolithic burial sites, mostly as isolated graves under rock shelters, are known in the Western alpine region of today Switzerland, France and Italy. Similar to other contexts, the transition to a sedentary lifestyle brought about a substantial change in funerary practices. With our ongoing Swiss National Science Foundation supported research project we want to understand how the burial customs of the first Neolithic populations in the western Alpine region became established and changed over time.

Here we present a synthesis of available radiocarbon dating of human remains. This allows us to test hypotheses about the chronological development of the cist graves ritual in the western alpine region. Anthropological data about sex and age-at-death of the buried individuals provide preliminary insights about the possible influence of gender and life course stages in the funerary practice.

The first necropolises date to ca. 4800 BC and include uniform cist burials made of wood- or stone slabs. In the following millennium, a wide range of funerary practices, including single inhumations, collective graves, primary- and secondary inhumations can be detected. These burial complexes were placed in distinct areas, outside of settlements and often used over centuries. This hints at the public character of the funerary rituals, and to a central social relevance of necropolises. After around 3800 BC, the cist grave burials disappear followed by gradual transformation of the funerary rituals and grave architecture. This period culminates, around 3300 BC, with the emergence of collective burials in large megalithic dolmen structures.

8 THE CHURCH AND THE TOWN - URBAN RELIGION DURING THE 10TH - 12TH CENTURIES IN ODENSE, DENMARK

**Abstract author(s):** Haase, Kirstine - Bjerregaard, Mikael (Odense City Museums)

**Abstract format:** Oral

The transition from Viking Age to the Middle Ages marks the beginning of two landmark events in Danish history, namely the introduction of Christianity and the rise of cities.

Christianity had a significant influence on cities’ design, with the founding of churches, monasteries, and cemeteries. This paper will present results from a research project revolving around one of these monuments; the first church (St. Alban) in Odense, a Danish city founded in the 10th century. In 1086 AD King Cnut IV (the Holy) was killed in the church of St. Alban and subsequently canonized.

These events seem to have had a profound impact on the city’s physical layout and its role in society – related to its position as a religious centre and a place of pilgrimage. However, less attention has been paid to the mutual shaping and transformation of urban space, urban life, religious practices, and ideas. Therefore it is central to the research project if there is a specific urban character to religious practices and beliefs taking place in the city.

Based on source material from large-scale archaeological excavations and written sources this paper will discuss 1) how we can trace changes in religious practices through material culture 2) how the role as a site of pilgrimage for a martyred king intersects with the negotiation between everyday urban life and religious practices and 3) how religion played a fundamental part in the early phase of the Scandinavian urbanization process.

381 CHILDREN OF THE BRONZE AGE: CONNECTING EUROPE FROM THE TIME OF BELL BEAKERS TO THE URNFIELD PERIOD

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Herrero-Corral, Ana (Universidad Complutense de Madrid) - Guba, Szilvia (Ferenc Kubinyi Museum)

**Format:** Regular session

During the Bronze Age important transformations of the funerary record are evident, with highly standardized rituals that spread and generalize throughout Europe. This has first been observed during the Bell Beaker period, in which despite the regional diversity, common patterns are detected, not only in the material culture but also in burial rituals. The universal character of different funerary rites endured even after the practice of cremation was introduced during the Tumulus and Urnfield periods. All these characteristics reflect intense connections between remote areas of Europe, which is proved not only by material culture but also by recent archaeogenetic data. Behind those innovations there are some crucial social, economic and ideological changes which demand an explanation.

This session explores the function that non-adult individuals would have had in these processes. The analysis of their graves permits to explore on one hand the social role of this age group in the transmission of cultural innovations and on the other hand the eventual inheritance of status during a period of incipient hierarchization. Graves are optimal contexts to analyze both aspects since the funerary behavior contributes to the creation and sustaining of social order. They also represent the perfect environment to develop political and ideological manipulations to achieve certain lineage’s aspirations such as perpetuating their power. In fact,

inheritance of power is one of the features of any hierarchical society and elitist non-adult graves have frequently been mentioned as some of the clearest indications of this process.

**BELL BEAKER CHILDREN: CONNECTIONS AND SOCIAL COMPLEXITY IN A TIME OF PROFOUND CHANGES ACROSS WESTERN EUROPE**

**Abstract author(s):** Herrero-Corral, Ana (Universidad Complutense de Madrid)

**Abstract format:** Oral

One of the main characteristics of the Bell Beaker period is its standardized funerary pattern. This uniformity is largely reflected in the homogenous grave goods (vessels and metal objects) spread, with some regional variants, throughout Europe, but also in the particular characteristics of the tombs, which make them different from those of the rest of the population.

Through the study of Bell Beaker non-adult graves it is possible to understand the role that boys and girls played within their communities. If we accept that Beaker elements were special items of restricted use and high symbolic value and thus related to social status, the fact that young children were also buried with some of these objects would refer the eventual inheritance of the status. Furthermore, the careful analysis of non-adult Bell Beaker graves in Iberia has shown that those children not only were they buried like the adults, but also had an additional age-based identity, that of a child.

**BORN AS PRIVELEGED? CHILDREN FROM THE EARLY BRONZE AGE CEMETERIES IN KOLÍN AND MIKULOVICE (BOHEMIA)**

**Abstract author(s):** Langova, Michaela (Institute of Archaeology of the Czech Academy of Sciences, Prague) - Vélková, Lucie (National museum, Prague) - Šumberová, Radka - Brzobohatá, Hana - Ernée, Michal (Institute of Archaeology of the Czech Academy of Sciences, Prague)

**Abstract format:** Oral

Despite of considerable attention dedicated to the research of the Early Bronze Age in Bohemia (Únětice Culture), the topic of children is still marginalized. Up to now more than 750 children remains from the Únětice Culture are known from this region. Unfortunately, large part of these data comes from old excavations with no anthropological analyses etc. This contribution focuses on the testimony of recent explored cemeteries in Kolín and Mikulovice, which brought to light an interesting amount of children remains. Together there were excavated human remains of almost 200 individuals from which one quarter belonged to children. As it is usual the category of foetuses or newborns was not detected, the youngest buried children were 2-3 years of age at death. Sufficient amount of samples enables to consider children graves among each other on the one hand and children versus adults on the other. It offers also the possibility to assess the funerary treatment under the local society as well as to compare these results between two contemporary communities and subsequently to contribute to better understanding of social role and position of children within the frame of whole Únětice Culture.

**SOCIAL ROLE OF CHILDREN DURING THE EARLY AND MIDDLE BRONZE AGE IN WESTERN HUNGARY**

**Abstract author(s):** Melis, Eszter (Institute of Archaeology, Research Centre for the Humanities, ELKH; Castle Headquarters Integrated Regional Development Centre Ltd.)

**Abstract format:** Oral

The territory of Western Hungary in the Early and Middle Bronze Age (2200-1500 cal BC) represented a border and contact zone among communities with different burial traditions: inhumation graves of Únetice related groups (Gáta-Wieselburg), biritual sites of the Kisapostag group, cemeteries with cremated burials of the Encrusted Pottery and Vatia culture. The study of burial evidence has the potential to provide important insights into the agency of children and their relationship with adults in society. The age distribution of altogether 507 individuals, out of which 185 were buried under the age of 20, from 14 sites west from the north-south flow of the Danube is being taken into consideration and analysed briefly here. I am also interested in exploring whether the ways children were buried at these sites showed any divergence from the normative mortuary treatment adults received and if so, how these divergences may be related to different age categories. My third enquiry focuses on the examination of grave goods such as dress ornaments, weapons and tools in the burials of children, which could shed further light on how gender roles and social status was conceptualized by Bronze Age communities. In addition, I attempt to discuss if the rich burial assemblages of non-adults achieve certain lineage's aspirations such as perpetuating the power or social rank was rather earned through personal achievement in their community.

**CHILD BURIALS IN MYCENAEAN CHAMBER TOMBS FROM GLYKA NERA, ATTICA**

**Abstract author(s):** Vrettou, Irene (Greek Ministry of Culture and Sports)

**Abstract format:** Oral

Among the newest discoveries of the Mycenaean cemetery of Glyka Nera are two chamber tombs which were excavated between the years 2007-2012. The first one hosted a single child. The gifts that accompanied this burial date it to the beginning of the LH

IIIB period. The second chamber tomb contained 23 burials, male, female and children. More specifically, children remains of various ages were discovered in pits inside the burial chamber and among swept away bones. The tomb was used mainly during the LH IIIA2-B1 period.

In this study we will first present the findings that are related to the child burials of both tombs and led us to identify them as such. Subsequently and more importantly, we will try to examine the similarities and contrasts between the two chamber tombs, the distinct manner in which each child was buried and the reason why their families chose that manner. The results will give us important information about the customs of child burial and the social conditions in the region of Glyka Nera during the LH IIIB period.

**KIDS FIRST! AGE-RELATED DIVISIONS OF CREMATIONS IN NORTHERN GERMANY DURING THE URNFIELD PERIOD**

**Abstract author(s):** Schaefer-Di Maida, Stefanie (Institute of Pre- and Protohistoric Archaeology, CAU Kiel; CRC 1266) - Storch, Susanne (abp Anthropologie Berlin)

**Abstract format:** Oral

At the site of Mang de Bargen (Bornhöved, district Segeberg, federal state Schleswig-Holstein, DE) a cemetery was investigated which shows burials from the Late Neolithic to the pre-Roman Iron Age. While up to the Middle Bronze Age inhumation burials were carried out in barrows, the change from inhumation to cremation burials from 1300 BCE onwards led to cremation graves secondarily in barrows and the surrounding. In comparison to the Older Bronze Age graves, which show strong differences in burial construction and grave goods, these secondary burials of the Younger Bronze Age show a pronounced similarity in burial rites. An egalitarian society is therefore conceivable very often in such contexts in Schleswig-Holstein. However, at the site of Mang de Bargen social diversities can be seen in the grave furnishings as well as in the positioning of the graves. Anthropological analyses of these cremations show that the graves of sub-adults were treated in a special way: they were buried in groups in the immediate vicinity of the barrows and in partly special grave vessels. Differences can also be observed not only between young and old individuals but also between sub-adults at the same site in the way they were buried. Comparisons with other sites in Schleswig-Holstein, whose cremations were analysed within the scope of the same project, allow similar conclusions. The Younger Bronze Age, which often has been reported to be so egalitarian throughout Schleswig-Holstein, is thus loosened up by age-related divisions or even stratifications. This hypothesis will be presented and discussed against the background of contexts, finds, absolut datings and latest anthropologic analyses.

**THE IMPORTANCE OF NONADULTS IN LATE BRONZE AGE BELGIUM – A MULTI-PROXY APPROACH**

**Abstract author(s):** Sabaux, Charlotte (Ghent University; Université libre de Bruxelles) - Veselka, Barbara - Snoeck, Christophe (Vrije Universiteit Brussel) - Capuzzo, Giacomo (Université libre de Bruxelles) - Sengeløv, Amanda (Université libre de Bruxelles; Ghent University) - Hlad, Marta (Vrije Universiteit Brussel; Université libre de Bruxelles) - Warmenbol, Eugène (Université libre de Bruxelles) - Stamataki, Elisavet (Vrije Universiteit Brussel; Université libre de Bruxelles) - Vercauteren, Martine (Université libre de Bruxelles) - De Mulder, Guy (Ghent University)

**Abstract format:** Oral

A deficit of nonadult graves has been observed in a wide range of archaeological excavations. Several factors could be at play, such as a difference in funerary practices between adults and nonadults, partial excavation of the sites or possibly the small size of nonadult remains, especially when cremated. The site of Herstal, and its 21 Late Bronze Age cremation graves, offers a unique opportunity in the Belgian Meuse valley to improve our understanding of nonadult funerary rites and their potential social status using typology, grave goods, osteology, and strontium isotope analyses. Among the deceased, a relatively large number of nonadults (44%; 11/23) was discovered. Based on multi-proxy analyses, funerary rituals are determined to have been similar for adults and nonadults, as it was also observed in other cemeteries from the same period (e.g., Ireland, Scotland, Scandinavia, and in the southern Carpathian Basin). However, one grave reveals the somewhat unique presence of multiple nonadults buried together in an urn as opposed to other cemeteries where commonly nonadults are buried together with at least one adult. One of these nonadults was aged between 7 and 12 years and based on the age and the grave goods, this individual could already have been considered as an adult within this community. This research shows that multi-proxy analyses improve our understanding of changing social roles and significantly contributes to our understanding of the funerary practices in the Middle Meuse Valley and more broadly for the Late Bronze Age.

**CHILDHOOD IN PROTOHISTORY IN THE SOUTHERN CARPATHIAN BASIN: EXAMPLES FROM THE URNFIELD PERIOD**

**Abstract author(s):** Ložnjak Dizdar, Daria (Institute of Archaeology, Zagreb) - Rajić Šikanjić, Petra (Institute for Anthropological Research, Zagreb)

**Abstract format:** Oral

Childhood in protohistory in the southern Carpathian Basin is a research project funded by the Croatian Science Foundation. The research objectives of the project are: to determine the biological age and gender of the children; to research the social age of children in protohistoric communities and to recognise life phases in young populations of protohistoric communities. Project team try to reconstruct the everyday life of children by analysing different material traces, especially through the data on health, diet, costume,

and personal items. Multidisciplinary interpretation of the collected data give us insight into play, work, the children’s relationship to their environment, and child-related rituals. The goals of the project is researched on three levels: each community separately; within a time period and diachronically through protohistory from the 14th century BC to the 2nd century BC within the chronological framework.

The envisaged multidisciplinary research (archaeology, anthropology, residue analyses, stabile isotope analyses) use the archaeological context of the found material traces of children and their activities as the basic criterion for researching childhood in the past. Planned and controlled analyses within natural sciences will provide more knowledge on the diet and ritual of protohistoric communities. A joint interpretation will provide a more comprehensive view of the past through current methodologies of research applied to the archaeology of childhood.

Some examples from the Late Bronze Age communities in the southern Carpathian Basin will be presented in this paper. The biological and social age as well as the funerary context will be used in the reconstruction of their role in the hierarchy of a particular community and the change of perception through the period of the Urnfield culture.

**BABIES IN FLAMES – CREMATION AS A SOCIAL ACT?**

**Abstract author(s):** Guba, Szilvia (Ferenc Kubinyi Museum) - Köhler, Kitty (HAS)

**Abstract format:** Oral

The funerary landscape in Late Bronze Age Carpathian Basin shows great variation with spectacular burial mounds on one hand and almost unrecognisable cemeteries on the other. Although funerary practises are in general very strict, the burial rites (disposal of the body, arrangement and structure of the graves) show great diversity within regions or even in different cemeteries. In NE-Hungary and in the southern areas of Central Slovakia, the Late Bronze Age is marked by the cultural phenomenon of the Piliny and the subsequent Kyjatice cultures. Until today, there are about 160 cemeteries and 5300 individual burials known, which are – with just a few exceptions – all incinerations. Although a great deal of grave types and attributes are recognised and funerary acts might have changed during centuries, one basic act, the manipulation of the body with fire remained constant. This fact applies even for children, regardless of age or sex.

In our presentation we would like to highlight some aspects of non-adult LBA burials based on recent investigations. One important aspect is, when non-adults become part of the society. The idea of rites the passage manifests a specific age when children become fully accepted within the community. Archaeological record show that already by birth (and/or followed by rituals) they are recognised as full members: they are buried within the cemetery by getting the same treatment as adults. The anthropological data also suggest, that cremation itself was conducted in the same manner for children or even prenatates, e.g. burning the bodies on separate pyres, collecting the cremains in vessels. This paper discusses some of the archaeological evidence, when special attention was given to children in Late Bronze Age funerary practices.

**A. FORGOTTEN BABIES? THE YOUNGEST CHILDREN IN THE EARLY BRONZE AGE IN CENTRAL EUROPE**

**Abstract author(s):** Hladikova, Katarina (Comenius University, Faculty of Arts, Bratislava) - Véllová, Lucie (National museum in Prague) - Daňová, Klaudia (Institute of Archaeology SAS Nitra)

**Abstract format:** Poster

In recent years the subdiscipline archaeology of children and childhood has generated increasing scientific interest. Our project takes a closer look at children remains in archaeological records from Central European Early Bronze Age, especially in the area of Middle Danube. The collection of analysed children remains comes from different culture contexts and offers insight into construction of children personhood, their social identity and roles in the prehistoric communities.

This poster opens a discussion concernig (in)visibility of the youngest children (up one year including foetuses) in the archaeological record based on the contextual analysis of their remains and material evidence. The results of the analysis indicate high variability of the infant remains treatment (single graves, double and multiple graves and depositions, pithoi burials) and regional differences. The revealed differences among treatment of foetuses, newborns and infants could reflect slightly changing social position of children during childhood in relation to the age, gender, kinship and related social status.

**B. AN INFANT BRONZE AGE FUNERARY CONTEXT FROM EL PENDO CAVE (CANTABRIAN SPAIN): THE ROLE OF CHILDREN IN RITUAL SPACES**

**Abstract author(s):** Camarós, Edgard (McDonald Institute for Archaeological Research - University of Cambridge) - Cueto, Marián - Higuero-Pliego, Antonio (Instituto Internacional de Investigaciones Prehistóricas de Cantabria - IIIIPC. Universidad de Cantabria) - Martín-Seijo, María (Departamento de Ciencias Históricas. Universidad de Cantabria) - Cubas, Miriam (Departamento de Historia y Filosofía. Universidad de Alcalá; Sociedad de Ciencias Aranzadi) - Teira, Luis (Instituto Internacional de Investigaciones Prehistóricas de Cantabria - IIIIPC. Universidad de Cantabria) - Ruiz-Cabanzón, Alba (Universidad de Cantabria) - Arias, Pablo (Instituto Internacional de Investigaciones Prehistóricas de Cantabria - IIIIPC. Universidad de Cantabria)

**Abstract format:** Poster

El Pendo Cave (Cantabrian Spain) is a well-known Palaeolithic archaeological site listed in the World Heritage by UNESCO. Nevertheless, the site preserves outstanding evidence of a Bronze Age context defined by the presence of non-sedimented circular

structures, organic material (i.e., cordage, crafted wood and bark elements), metal objects and abundant pottery. Decontextualized human remains were also present at the site and collected during previous excavations. The Bronze Age context has been described as a ritual votive area, similar to others identified in Cantabrian Spain. Among other evidence of a non-domestic use of a specific area of the El Pendo Cave, an infant funerary assemblage has been located. A 1.5-2 years old individual was placed between two rocks within the ritual votive context. What role did this child play among ritual activities at El Pendo Cave? How does this funerary context link with sacred spaces during Bronze Age in Northern Iberia? Is there evidence of differential treatment when comparing with funerary contexts associated to adults? Was El Pendo Cave used as a collective funerary context?

In the present contribution, we face all those questions with the aim of defining and contextualizing the infant funerary unit at El Pendo in the context of significant social change observable through funerary and ritual variability and changes.

**FROM THE FIELD TO THE COMPUTER. THE VALIDITY OF QUANTITATIVE METHODS REGARDING THE QUALITY OF ARCHAEOLOGICAL DATA**

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Cortell-Nicolau, Alfredo - Pardo-Gordó, Salvador (Departament de Prehistòria, Arqueologia i Història Antiga. Universitat de València) - Perrin, Thomas (Université Toulouse. CNRS)

**Format:** Regular session

Measuring archaeological diversity has known a great theoretical and methodological development in the past decades. The inclusion of ever more sophisticated techniques, as well as thorough consideration of archaeological theory have provided current archaeologists with a useful toolset able to tackle different kinds of problematics and research questions. The analysis of radio-carbon datasets, the study of archaeological networks or the adaptation of different ecological techniques are just some of the methodological solutions that try to understand archaeology and bring solid explanations for past dynamics.

However, the archaeology’s Achilles’ heel has always been the quality of its data. How can we measure diversity without a clear understanding of archaeological units? How do we move on to synthetic research without a full reliance on our primary sources? What is the responsibility of field archaeologists producing information, and of theoretical archaeologists tailoring useful generalised methodologies?

In this session, we mean to build bridges between field archaeology and theoretical archaeology, from the acquaintance that one is useless without the other. We welcome all proposals trying to improve the recollection and understanding of primary data and how that can be translated into useful primary information. Also, we welcome any insight assessing the validity of the application of quantifying techniques (from ecological general solutions, to ad hoc developed methods) regarding the quality of the archaeological record.

**ABSTRACTS:**

**WHO CARVED? RUNIC INSCRIPTIONS FROM BERGEN, NORWAY**

**Abstract author(s):** Magin, Elisabeth (University of Nottingham)

**Abstract format:** Oral

Between 1955 and 1979, almost 700 runic inscriptions on small wooden sticks, ceramics and other objects were found on the Bryggen site in Bergen, Norway, dating to the 10th to the 15th century AD. Many of the objects carry little more but a name – but these names are significant. Traditional interpretations of runic inscriptions have often viewed runic script as an elite medium of communication, similar to the Latin alphabet. However, medieval Scandinavian names not only function as tools to properly identify and address individuals, but also as a way to express status and family affiliation. The names in the runic inscriptions therefore provide valuable clues regarding the potential social status of the rune-carvers; by extent, they therefore also provide clues to which parts of the population made use of runes for communication purposes.

This paper will discuss how comparisons between archaeological and manuscript sources can aid our understanding of medieval runic literacy within the context of a medieval trading town, by combining archaeological and onomastic data. It will further discuss how the data aspect of either side of the study has to be modelled to be able to employ a relational database and statistical methods like the Chi-Square-test for analysis.

**OBJECT TO SCREEN: RUNIC INSCRIPTIONS, LEGACY DATA AND A RELATIONAL DATABASE**

**Abstract author(s):** Magin, Elisabeth (University of Nottingham)

**Abstract format:** Oral

The Bryggen excavations (1955-1979, Bergen, Norway), represent one of the largest medieval archaeological excavations in Northern Europe, and a breakthrough in excavation methodology – from the very start, mechanical methods of data processing were used to store information about the roughly 100,000 finds.

As of 2021, the excavation has still not been fully published despite what, at first, appears to be fortunate circumstances. The data from the IBM cards has been transferred into a relational database, but that does not necessarily make it easier. The legacy data is of varied quality, and later evaluation of the materials raised doubts about, for example, the dating of artefacts. Either presents additional obstacles, for example when working with the roughly 700 runic inscriptions found during the excavations. These constitute a unique corpus of great importance for archaeologists, linguists, philologists and cultural historians alike, offering genuine impressions of daily life in a medieval town from the perspective of the inhabitants.

Analysing them as a corpus, however, requires first dealing with several obstacles: the legacy data of the excavations combined with the problems of adequately representing runological research in a database model allowing large-scale analysis of the material. This paper focusses on how the legacy data was carefully transferred into a data structure better suited to analysis by computer, and how the combination of proper data structure, legacy excavation data and runological data permits fascinating additional insights into the rune-carving population in Bergen.

### 3 A GLITCH IN THE MATRIX? HOW RE-USEABLE IS THE STRATIGRAPHIC DATA WE RECORD, ANALYSE, SYNTHESIZE OR PUBLISH?

**Abstract author(s):** May, Keith (HE - Historic England; University of South Wales) - Taylor, James (University of York) - Binding, Ceri (University of South Wales)

**Abstract format:** Oral

Stratigraphic laws and principles underpin the archaeological records from excavated sites and are essential for integrated analysis, wider synthesis and accessible digital archiving of the growing body of archaeological data and reports generated through the commercial archaeological sector in the UK and internationally. On most excavated sites, the stratigraphic record, most often visualized, and to a degree quantifiable, in the form of a stratigraphic matrix, acts as a primary, if not the primary piece of evidence for how, and in what order, the site was excavated. As such the stratigraphic record is the key mechanism that enables anyone less familiar with the site, to re-visit the excavation records, understand what data is most relevant for any research questions, or problems encountered, and piece together the underlying details of how the interpretations by the excavator(s) were arrived at.

However, such primary records are often only held on paper or scanned copies of matrix diagrams that cannot easily be re-used with associated data. Often the key phasing data needed for re-use in synthesis work and interpretive understanding, let alone Bayesian Chronological modelling, is not consistently documented, if at all, in written reports. This results in key records being unsearchable or remaining unconnected and lacking interoperability with other data (unFAIR).

The focus of digital archives and museums is now switching from simply providing better access to digital archives, to questions of how users in commercial units, curatorial organizations and academia, along with the general public, are going to make best use of this growing body of digital information and data.

This paper will present work undertaken by The Matrix project [AH/T002093/1] which is addressing some of the current problems caused by the lack of standardized approaches to analysis and digital archives of archaeological stratigraphic and phasing data.

### 4 TRUST IN NUMBERS OR TRUST IN DIGGERS? QUANTITATIVE AND SIMULATION-BASED METHODS TO ASSESS FIELD DATA QUALITY: STRATIGRAPHY AND REFITTING ANALYSIS

**Abstract author(s):** Plutniak, Sébastien (TRACES laboratory, Toulouse; Centre Émile Durkheim, Bordeaux)

**Abstract format:** Oral

Theoretical issues raised by the dialectical relationship between the quality of archaeological data and the quality of their modelling will be addressed from a methodological standpoint. I argue that 1) archaeological science needs to ensure the highest standards regarding each of these two aspects, and 2) that the theoretical problems must be addressed with regards to their consequences for operational methods. I will demonstrate this approach from the case of a new method to study the relationships between stratigraphic units and refitting, and related problems regarding the ontology of archaeological facts.

Refitting pieces have been long-used in archaeology to assess the consistency of discrete spatial units (e.g. layers) and to evaluate disturbances and post-depositional processes. Previous methods, despite their differences, relied on the count and proportion of refits within and between spatial units. Little attention was paid to the distribution and topology of the relations between fragments, although this can have significant effects on archaeological interpretation. The TSAR method (Topological Study of Archaeological Refitting), presented here, draws on concepts and methods from graph theory to model the network of connections observed between refitting fragments. Measures for the cohesion and admixture of spatial units are defined based on the topological properties of these connections.

In this approach, confidence in field data is evaluated and consolidated through modelling and quantitative methods, which are used in three related ways: 1) descriptive statistics, 2) ad hoc measurements (based on specific assumptions) of cohesion and admixture, and 3) testing of site formation hypotheses comparing the observed data against simulated data generated using the properties of the observed data.

Finally, the methodological need to model refitting relationships between objects and their relations with spatial archaeological units raises theoretical issues related to the elementary archaeological concepts, such as the very concepts of object, fragment, site, layer, etc.

### 5 NEW UNCERTAIN PREHISTORIC SITES: CONFRONTING ARCHAEOLOGICAL PALIMPSESTS USING BAYESIAN PROBABILISTIC METHODS APPLIED TO LITHIC ARTIFACTS

**Abstract author(s):** Gironès Rofes, Ivan (Departament de Prehistòria. Universitat Autònoma de Barcelona) - Pardo Gordó, Salvador (Departamento de Geografía e Historia. Universidad de La Laguna) - Molist Montaña, Miquel (Departament de Prehistòria. Universitat Autònoma de Barcelona)

**Abstract format:** Oral

The study of archaeological palimpsests tends to a common problem for the treatment of data, mainly characterized by the performance of analyzes with a lack of scientific and interpretative bases which are limited to the chronological and technological representativeness of the artifacts with the shortage of flexibility. The contrast of these data with the reference data currently available, therefore, they are associated according to qualitative criteria that are outside the total representativeness of the archaeological assemblages and without fixed bases that support them.

In this communication, it is intended to expose the construction of Bayesian models applied to lithic artifacts to confront these archaeological situations. Following its application to Valencian contexts, our objective is to approach a certain contextualization of the decontextualized with more solid bases identifying Prehistoric occupations (c. 13.400-4.200 cal BP) in the lower Ebro valley (Catalonia, Spain). Under this line, we will expose from the construction and criteria of the referential base (sampling, reliability of the absolute dating contexts used, etc.) to its application in case of studies with lithic assemblages without time and space associations, recovered in the fluvial terraces of the lower Ebro. Finally, we will emphasize the exposition of not solved problems to take stock of the effectiveness of the model.

### 6 INTEGRATING DATA FROM OTHER SOURCES AND EXPANDING THE ARCHAEOLOGICAL PERSPECTIVE: A CASE FROM ANATOLIA

**Abstract author(s):** Arikan, Bulent (Istanbul Technical University)

**Abstract format:** Oral

The connection between field archaeology and theory is a sensitive one. There is a two-way relationship; however, it is also fraught with problems concerning data quality. More often than not, hypotheses we build in archaeology require integrating data sets from various fields, and these datasets come with their own issues. This paper will focus on how to integrate ecological data into archaeology in north-central Anatolia. North-central Anatolia witnessed the social evolution from chiefdom to statehood, but archaeological research has been intermittent. There has been limited paleoecological research in this part of the Anatolian steppe. Due to the nature of the archaeological record and paleoenvironmental data, combining these groups for synthesis was never achieved. Adopting a holistic approach and re-assessing both archaeological and paleoecological datasets allowed us to build testable hypotheses. Consequently, the relationship between social evolution and past environmental conditions may be assessed through data sets that are better suited for synthetic research.

### 7 MANUAL AND AUTOMATED REDISCOVERY OF SMALL VILLAGE PONDS IN NORTHWEST INDIA, AND POTENTIAL CONTRIBUTIONS TO RESILIENT AND SUSTAINABLE WATER MANAGEMENT

**Abstract author(s):** Green, Adam (University of Cambridge) - Garcia-Molsosa, Arnau (Catalan Institute of Classical Archaeology) - Alam, Aftab (Banaras Hindu University) - Orengo, Hector (Catalan Institute of Classical Archaeology) - Petrie, Cameron (University of Cambridge)

**Abstract format:** Oral

Archaeological data can contribute substantially to interdisciplinary debates about sustainability and resilience, and can help guide policymakers to improve resource management in the present. Agricultural water management in South Asia is particularly critical in this regard. In northwest India certain kinds of anthropogenic surface water features, such as village ponds, appear to have played an important role in the region's deep history and can play a role in contemporary water management. These surface water features are critical in the region's distinctive environment, which receives significant rainfall from the Indian Summer Monsoon and additional input from the winter rains. However, before these features can be integrated into policy debates, it is necessary to identify them in the landscape, as well as their associations with settlements and other landscape features. After all, to understand the potential of these and similar features to mitigate the worst effects of climate crisis, data about them must be translated into units that are pertinent to interdisciplinary research; archaeological and historical data must be assembled into comparable units to contemporary data, and at scale. In this paper, we discuss the potential of historical maps and archaeological data to identify the extent of surface water in both the near and distant past. Using a combination of GIS, remote sensing, and historical analysis, we outline a new big data approach to the assembly of surface water data in northwest India. We focus in particular on the analysis of historical Survey of India maps that were prepared by British Colonial authorities nearly a century ago. We compare manual and automated methods of extraction, present a new machine-learning workflow, and explore the potential of these results to contribute to debates about resilience and sustainability in the face of a growing climate crisis.

**Theme:** 6. Material culture studies and societies

**Organisers:** Zeman-Wisniewska, Katarzyna (Uniwersytet Kardynała Stefana Wyszyńskiego w Warszawie) - Recht, Laerke (University of Graz) - Georgiou, Artemis (Cyprus American Archaeological Research Institute)

**Format:** Regular session

This session will explore social transformations in ancient Cyprus. Islands can be seen as laboratories of cultures and societies, and Cyprus is particularly fascinating in this regard, due to its rich material culture, with both internally and externally caused processes of social transformations, stemming from the island's geographical position within key Mediterranean maritime routes. The focus is on transitional periods, for example the so-called Philia phase between the Late Chalcolithic and the Early Bronze Age, the little understood Early Cypriot to Middle Cypriot and Middle Cypriot to Late Cypriot, the end of the Bronze Age and the beginning of the Early Iron Age and the transition from the Cypro-Classical to the Hellenistic period. Papers on any aspect of material culture and archaeological contexts that analyse transformations in social structures, economy or ideology are welcome. These can include, but are not restricted to, changes in settlement patterns, architecture, practices of production and consumption (e.g. ceramics, figurines, metalwork), human-environment interaction, intra- and extra-insular exchange networks and burial practices. We also encourage papers that question the conventional chronological standards and divisions themselves as they have been established and are used in scholarship today, closely examining their validity and usefulness. Such papers may in fact challenge the previously assumed transformations or our current chronological framework and terminology.

ABSTRACTS:

1 INTER-PERIOD TRANSITIONS: EXPLORING THE LONG-TERM HISTORY OF THE ACERAMIC NEOLITHIC THROUGH THE NEW CASE STUDY OF PYRGOS AYIA MARINA

**Abstract author(s):** Chelazzi, Francesca (University of Glasgow) - Menozzi, Oliva (Università 'G. D'Annunzio' di Chieti e Pescara) - Agostini, Silvano (Centro di Ateneo di Archeometria e Microanalisi - Università 'G. D'Annunzio' di Chieti e Pescara) - Ciarico, Alesandra - Di Valerio, Eugenio (Università 'G. D'Annunzio' di Chieti e Pescara)

**Abstract format:** Oral

The long-term history of human societies is characterised by major transformations, which usually coincides with macroscopic changes in settlement, material culture, technology, architecture, and socio-economic organisation. Especially where no sizable change is self-evident, there is usually a tendency to acknowledge ancient communities as 'monolithic' social bodies, with no distinction in space and time.

The Cypriot Aceramic Neolithic consisted of an extensive period (almost three millennia) when the island's earliest communities commenced manipulating their territories, through an increasing intensification of farming and grazing, and the development of symbolic and ideological thinking. The Aceramic Neolithic legacy of Cyprus includes old and newly excavated sites revealing regional sequences of 'inter-period' transformations in terms of chipped stone technology, architecture, and subsistence economy.

Pyrgos Ayia Marina is an excellent case study for exploring the evolution of the Aceramic Neolithic in Southern Cyprus, given its long-term occupation which preliminary radiocarbon dates place from the half of the 10th millennium to the 7th millennium BC at least. Whilst new radiocarbon analyses are in progress to date the entire sequence of occupation, the available chronology indicates the potential of Ayia Marina to yield new data about the so-called PPNA hiatus and – possibly – the 8.2 ka BP climatic event. The extended stratigraphy includes at least six distinct phases of occupation, alternated with episodes of abandonment, flooding, and accumulation of deposits.

The remarkable set of threats affecting the site provides an opportunity not to be missed to collect new data about the socio-economic transformation of Neolithic Cyprus, addressing a broad range of topics through a multi-disciplinary approach. New data in human-environment interaction, technology, production and consumption aims at filling some critical gaps in the archaeological knowledge, revealing that Aceramic Neolithic communities were not a changeless and 'monolithic' society.

2 VARIATIONS ON A THEME: REASSESSING THE PHILIA CONUNDRUM

**Abstract author(s):** Paraskeva, Charalampos (Archaeological Research Unit, University of Cyprus)

**Abstract format:** Oral

The transition from the Chalcolithic to the Bronze Age in Cyprus has been a topic of often heated debate amongst archaeologists working on the island since the discovery of a series of tombs at Philia-Vasiliko, which provided the earliest traces of Bronze Age cultural material in the 1940s and led to the establishment of the term Philia culture/facies to identify the transitional period prior to and leading into the Early Bronze Age. However, the paucity and poor publication of evidence regarding the material culture associated with this period, the absence of an island-wide typology for the Late Chalcolithic pottery; and the lack of temporal data for most sites dating to and around either side of the transition, have led to the adoption of interpretive perspectives that are more reliant on abstract archaeological theory than concrete material evidence. This tendency to emphasize theory over data tends to disregard data that cannot be explained by the former, promotes unilinear, often monocausal narratives regarding the transition, masks cul-

tural variations in the archaeological record, reduces the plurality of responses by agents of change to collective action, and ignores spatiotemporal differences in the rate and mode of managing technological, social, material, and cultural novelty. The present study proposes a radical realignment of the timeline and narrative for this transition based on re-examined and new data (bibliographic, chronometric, spatial, artefactual) spanning from the Late Chalcolithic to the Early Bronze Age and spatially covering nearly the entire island. In this regard, a multilinear explanatory model will be outlined, which allows for a longer overlap between the Chalcolithic and Bronze Age, accepts that change occurs at varying speeds; regions and perhaps sites emerge as primary actors of change, and the external versus internal agents of change debate is replaced by a complex web of dynamically interacting population groups.

3 BREAKING BOUNDARIES: EXAMINING TRANSITIONAL PERIODS AND TECHNOLOGICAL CHOICES IN PREHISTORIC SOUTH-WEST CYPRUS THROUGH POTTERY ANALYSIS

**Abstract author(s):** Menelaou, Sergios (University of Cyprus, Archaeological Research Unit) - Bolger, Diane (University of Edinburgh School of History, Classics and Archaeology) - Bombardieri, Luca (University of Turin) - Crewe, Lindy (Cyprus American Archaeological Research Institute)

**Abstract format:** Oral

Pottery, and ceramic artefacts in general, are sensitive markers of technological and socio-economic transformations and their detailed analysis holds a key position in investigating in a more tangible manner developments in social structures, craft practices, past interaction and external influence, connectivity and mobility, and human-environment interactions. In fact, recent years in Cypriot studies have witnessed an increasing concern towards pottery's technological significance from a rather scientific perspective, moving beyond morpho-stylistic and typological approaches. These have so far made clear that the ceramic regionalism evident across the island shows distinct differences between the north/centre and south/west of the island from at least the Philia phase onwards. Until recently, stylistic and typological sequences were constructed almost entirely on the basis of tomb finds from cemeteries excavated in northern Cyprus. This fragmented picture has, however, started to change through the investigation of settlement sites in south-west Cyprus with the examples of Kissonerga-Mosphilia, Kissonerga-Skalia, and Erimi-Laonin tou Porakou. This paper will discuss the preliminary results of a targeted combined macroscopic and petrographic analysis of ceramic samples from the three aforementioned sites, which will enable important insights into synchronic and diachronic developments in Chalcolithic through Middle Bronze Age Cyprus, with a special concern with how these developments are imprinted in the transitional phases. Through these case studies, aspects of ceramic manufacture and technology at the micro-scale level will be illuminated, alongside the examination of continuity and/or change in local technological traditions, breaking away from monolithic chronological boundaries and transitional periods. Beyond the establishment of the local ceramic profiles, the examination of technological influences at an intra-island and inter-regional level will be attempted.

4 ABANDONMENT PRACTICES IN THE TRANSFORMATIVE MIDDLE BRONZE AGE CYPRUS

**Abstract author(s):** Amadio, Marialucia (Dipartimento di Civiltà e Forme del Sapere, Università di Pisa) - Bombardieri, Luca (DF-CLAM, Università di Siena)

**Abstract format:** Oral

The characterization of abandonment practices is a key topic in archaeological discussion as it provides an excellent arena to analyse social and historical processes in ancient communities (e.g. Cameron 1991; Cameron and Tomka 1993; Stevanovic 1997, 2002; Verhoeven 2000; Twiss et al. 2008; Driessen 2013). If the construction of a building may offer evidence of the formation of social identities, roles and statuses, the analysis of abandonment dynamics may provide significant data to examine the way these identities are reinforced, maintained or -alternatively- negotiated through social practices for individual households and across generation in the longer term.

In this view, the proposed paper aims at presenting a fresh perspective on socio-cultural practices and dynamics during the Middle Bronze Age in Cyprus. In this period, new social identities, roles and relationships emerged, transforming a household-based society into a more complex social system, which would ultimately develop into the urban centres of the Late Bronze Age (Webb and Knapp 2021). While the evident outcome of this process, the ex-novo foundation of cities in the Late Cypriot (LC) II period, has received ample attention, complex abandonment phenomena and destruction practices of Middle Bronze Age centres deserve further investigation as part of the same overarching process of social transformation.

New evidence resulting from integrated analyses conducted on abandonment sequences at Middle Bronze Age Erimi will be presented along with a reassessment of data from abandonment contexts of coeval settlements in Cyprus in order to attempt a reconstruction of the causes that triggered the abandonment of these centres. The final purpose is to stimulate a discussion about possible social, cultural, political and ideological circumstances behind the identified abandonment practices of Middle Bronze Age contexts in Cyprus.

5 **TRADITION AND INNOVATION DURING THE 12TH-TO-11TH CENTURY BC TRANSITION IN CYPRUS: NEW DATA FROM THE KITION-BAMBOULA SETTLEMENT**

**Abstract author(s):** Georgiou, Artemis - Georgiadou, Anna (University of Cyprus) - Fourier, Sabine (Laboratoire HiSoMA, Maison de l’Orient et de la Méditerranée)

**Abstract format:** Oral

The transition from the 12th to the 11th century BC in Cyprus constitutes a critical junction that marks the close of the Late Bronze Age and the inception of the Early Iron Age. This transformative phase remains poorly known and ill defined, not least because of the remarkable dearth of stratified settlement strata exposed to this day on the island.

Recent investigations by the French Archaeological Mission at Kition, within the locality of Bamboula, situated on the northern part of the modern-day town of Larnaca, have brought to light a continuous stratigraphic succession of floor layers spanning from the 13th to the 11th centuries BC, thus marking an exceptional instance on an island-wide basis.

The aim of this contribution is to provide a comprehensive presentation of the stratigraphic, architectural and artefactual remains exposed at Kition-Bamboula that provide crucial new data for the transitional 12th-to-11th century BC horizon. In particular, through the contextual analysis of well-stratified pottery remains, the study aims to discuss the transformations observed on the island’s ceramic repertoire and especially as regards the impact of the endorsement of wheel-made technology for the production of ceramic finewares. The study will also elucidate the extra-insular connections maintained by the cosmopolitan harbour town at Kition, based on the analysis of the plethora of Levantine maritime transport amphorae contained within the settlement’s pertinent levels. Finally, this presentation will discuss a series of idiosyncratic phenomena, such as infant jar-burials and purple-dye production, dating to the settlement’s transitional phases of the 12th and 11th centuries BC. Ultimately, our contribution aspires to shed light on the continuities and innovations characterising the Cypriot material culture and the transformative capacities of the island’s communities at the dawn of the Early Iron Age.

6 **TRANSFORMATION & DEEP TIME: ANIMALS IN PREHISTORIC CYPRUS**

**Abstract author(s):** Recht, Laerke (University of Graz)

**Abstract format:** Oral

Animals have always had a central role in human lives, as a resource, as companions and as determining lifestyles, among many other things. This paper will examine the transformative powers of animals in Prehistoric Cyprus. Cyprus is particularly suited for this kind of study as an island where we can trace which animals travelled with humans. From the first human visitors through increased settlement to the end of the Bronze Age, human-animal relations were incredibly varied and catalysts for changing lifestyles. Marine animals, mammals and birds were not only the basis for fishing, hunting, pastoralism and agriculture, but also represent ways in which humans interact with other animals and their environment more broadly. The earliest humans on the island appear to have primarily interacted with indigenous species, to the extent that it may even have caused extinctions of some species. The next visitors settled more long-term and brought with them species such as deer that could be hunted, while pigs, sheep and goats involved more intimate relations and new technologies. The Prehistoric Bronze Age introduced larger mammal species such as cattle and donkeys that aided in agriculture and overland transport; later in the Protohistoric Bronze Age, horses became an integral part of international trade and relations. Each animal species imply a range of relations between human and nonhuman animal and some were indeed transformative for both humans and nonhumans.

7 **DOVES AND PIGEONS IN THE BRONZE AGE CYPRUS – TRACING CHANGING HUMAN-BIRD RELATIONS**

**Abstract author(s):** Zeman-Wisniewska, Katarzyna (Uniwersytet Kardynała Stefana Wyszyńskiego w Warszawie)

**Abstract format:** Oral

Columbidae are birds common in Cyprus, both nowadays and in the past, as local, migratory and domesticated animals. Doves and pigeons also hold a special, symbolic place in the human culture of ancient Cyprus, as sacred birds of the most Cypriot deity – Aphrodite. However, their presence in iconography, cult... and cuisine can be traced much further back, then the oldest remnants of the goddess’ sanctuary in Paphos. Their bones were identified within Epipaleolithic bone assemblages, which makes them one of the first hunted animals in the island, thus one of the reasons for the early human presence here. During the Bronze Age doves and/or pigeons became visible in the Cypriot iconography. In the Early Bronze Age dove-shaped figurines were often attached to vases associated mostly with graves, which points not only to their symbolic role in cult, but probably also in changing agricultural practice and human-animal relations. In the Late Bronze Age presence of those birds in iconography (i.e. vessels, glyptic) connected with cult activities depicts doves (and/or pigeons) probably as sacrificial animals. This paper discuss changing human-bird relations within changing social and environmental context of the Bronze Age Cyprus.

8 **FARMING THE BIG ISLANDS OF THE MEDITERRANEAN: CRETE AND CYPRUS IN THE BRONZE AGE**

**Abstract author(s):** Margaritis, Evi - Henkel, Carly (The Cyprus Institute)

**Abstract format:** Oral

The exploitation and exchange of natural resources has been a key parameter in the survival and evolution of past and modern societies. Subsequently, specialisation and control of these resources constitutes a major indicator of increasing social complexity.

In the Mediterranean, aspects of social change such as urbanisation, technological sophistication and agricultural diversification, intensification and extensification are evidenced from the later fourth into the second millennia BC but also during the late Iron Age and the Archaic period. Although these developments have been extensively studied in the past, archaeobotanical approaches – and so a whole swathe of crucial evidence – have not been brought to bear on these questions, with notable exceptions. This paper will explore these aspects of research in two similar islands of the Mediterranean, Crete and Cyprus. The focus of the paper will be the 2nd millennium, a period of major transformations, which will be approached through the lens of the archaeobotanical remains.

9 **CYPRUS™: LOOKING FOR BRANDING PRACTICES IN LATE BRONZE AGE CYPRUS**

**Abstract author(s):** Meneghetti, Francesca (Independent researcher)

**Abstract format:** Oral

During the Late Bronze Age, Cyprus plays a pivotal role in Eastern Mediterranean trade networks. Even though the island lacks deciphered written evidence on its political organization, the archaeological record shows Cypriot elites who gained political and economic power thanks to overseas trade, thus having a political and entrepreneurial role in local society (Sherratt 2016).

After the collapse of the palatial system and related commercial networks (end of 13th cent. – beginning of 12th cent. BC), Cyprus and its elites survive the crisis and thrive. These elites are mostly recognizable from the rich mortuary data, which gives only a partial overview of these people. In this paper, I argue that it would be possible to spot entrepreneurial elites from other markers, such as branded commodities and branding practices (e.g., marks, potmaks, iconography, writing). I will address the topic using available sociological works on brands (Arvidsson 2005; De Waal Malefyt 2018; Holt 2006; 2003), to set out a theoretical approach applicable to goods and trades in the Late Bronze Age Eastern Mediterranean. Thus, the paper aims to shed further light on the Cypriot society in a transitional period, as the end of the Late Bronze Age.

10 **FROM ISOLATED DATA SILOS TO AN INTEGRATED AND MULTI-PROXY REGIONAL SYNTHESIS. INSIGHTS IN A PAN-MEDITERRANEAN APPROACH TO HUMAN-ENVIRONMENT-CLIMATE INTERACTION**

**Abstract author(s):** Chelazzi, Francesca (University of Glasgow)

**Abstract format:** Oral

Data integration in Mediterranean and Near Eastern archaeology has become a very fertile area of research in the last decade, exploring how to aggregate and compare the many legacies that archaeology has produced over time. An increasing body of intersectoral research projects has developed and tested new methodologies to explore the varying nature of human responses to environmental, climatic and societal transformations. These projects that have opened up the potential of using Big Data in archaeological research including radiocarbon, landcover, satellite, botanical, zoological and genetic datasets and general (climate) circulation models (GCMs) that can be mapped onto each other in order to examine long-term, large-scale trends in different datasets calibrated against each other.

Is Cyprus ready for the challenge? This paper explores some methodological problems that might emerge when applying these multi-proxy techniques to the Cypriot datasets. Preliminary problems include the many sources of bias related to temporal uncertainty and the reliance on traditional typo-chronological schemes for historical periods. While radiocarbon dates from Cyprus suggest that new techniques such as the Summed Probability Distribution (SPD) might be coupled with probabilistic modelling techniques inferred from archaeological data (e.g. raw site counts, summed settlement area, aoristic sum), major problems arise when dealing with pollen cores, pollen-inferred land cover models and locally acquired climate proxies.

The purpose of this paper is to highlight the potential of this new ‘season’ of multi-proxy techniques, to prepare Cypriot archaeology for this exciting challenge where the island can successfully become a solid bridge within the reconstruction of the Holocene history of the Mediterranean region.

11 **POLYGONAL COLUMNS IN ARCHAIC CYPRUS**

**Abstract author(s):** Emanuelsson-Paulson, Therese (Classical Archaeology and Ancient History, Department of Archaeology and Ancient History, Stockholm University)

**Abstract format:** Oral

Archaic polygonal columns are found in Amanthus, Idalion, Kition, Marion and Palaepaphos, where the latter is the only site with numerous examples and the polygonal shape might even be more common than other column shapes. The inspiration for polygonal columns has been sought in Egyptian or Mycenaean architecture, but probably the Assyrian and Hittite use of polygonal columns down to the 7th century BC is a more likely source of inspiration. These columns mainly carries Leaf or Helmet capitals, where the former is inspired by Assyrian or Phoenician capitals, while the later might be a local invention. In the same period similarly shaped polygonal columns with Doric capitals appears in Greece, likely originating from the same inspiration or possibly secondary inspired from Cyprus. Simultaneously in both regions, the polygonal columns vanish around 500 BC, when the war with the Persians escalates.

A decorated column is not a necessary; a wooden pier would often suffice. Columns and decorated architecture in general, were most often used to express once wealth, status or identity, either within the own group or collectively towards other groups of people. The use of polygonal votive columns dedicated in the open air sanctuary in Palaepaphos seems therefore to be a local religious tradition similar to the Phoenician or Canaanite sanctuaries. The column from Kition also originates in a sanctuary, next to a Phoe-

BETWEEN THE KINYRAD TRADITION AND THE COSMOPOLITAN NEA PAPHOS

**Abstract author(s):** Mlynarczyk, Jolanta (University of Warsaw)

**Abstract format:** Oral

Dramatic shifts in the political power that took place within the Eastern Mediterranean after the conquest by Alexander the Great were inevitably connected to many social changes including the foundation of new towns, the rise of civic institutions and new facets of the religious life. With the abolition of Cypriote kingdoms and establishing a new centre of power in Alexandria, the island became a place of residence for many foreigners, including representatives of the Ptolemaic administration and mercenary soldiers from all parts of the Greek world whose presence on the island must have been felt in the life of the local communities.

All these changes influenced also one of the most conservative regions of Cyprus, the former kingdom of Paphos. Its culture, firmly rooted in the indigenous tradition of the LBA, at the same time featured Greek cultural ties as well as some links to Phoenicia religion. A special impetus to the changes in the life of the Paphians was given by the foundation of Nea Paphos between 321 and 310 BC.

Essential evidence for the transition from the Cypro-Classical to the Hellenistic period in the Paphos region are, in addition to scanty written and epigraphic sources, archaeological records of material culture, among which the ceramic finds are perhaps the most relevant. They may reflect the patterns of external contacts, the material/social status of inhabitants, sometimes also specifics of the local economy. The examination of all available sources demonstrates that the transitional period in question lasted well into the 3rd century BC. It is only in the 2nd century BC that Cyprus became fully absorbed into the Hellenistic koine in all aspects of her culture, as evidenced by e.g. the iconography of divine representations, or disappearance of inscriptions both in the Cypriot syllabary and the Phoenician alphabet.

CULTURAL SHIFT OR SHORT FASHION? HELLENISTIC BRAZIER FROM THE AGORA OF NEA PAPHOS, CYPRUS IN A GEO-POLITICAL AND SOCIO-ECONOMIC CONTEXT

**Abstract author(s):** Nocon, Kamila (The Polish Centre of Mediterranean Archaeology, University of Warsaw)

**Abstract format:** Oral

One of the benchmarks of the Hellenistic material culture were portable braziers, available to probably most areas and regions of the Hellenistic Eastern Mediterranean. One of the major theoretical issues that have dominated the field for many years concerns the social and symbolic function of braziers which were traditionally connected with the preparation and processing of food or interpreted as a type of altars associated with rituals of a religious nature, often combined with commensality of meat, also interpreted as incense for domestic cults. Studies over the past two decades have provided important information concerning braziers as a tool to create images of certain aspects of daily life and to come to the social and cultural principles of the communities they examine, but they are also bound into a description of local coarse ware ceramic production, by investigating how their fabrics were related to other contemporary pottery reveals the context of their production. The present study aims to offer a preliminary overview of braziers from the excavations at the Agora in Nea Paphos excavated during several research seasons. The main intention is to indicate presumably local production as well as examples manufactured outside Cyprus in the Hellenistic period. To date, there have been no reliable studies combing the presence of the braziers in Nea Paphos with socio-economic interpretation supported by archaeological and historical data. This study seeks to obtain data that will help to address research gaps in the material culture of the Hellenistic Nea Paphos and deepen understanding of the broader process of Hellenization.

MOVING WITH THE TIMES: SOCIAL CHANGE AND RITUAL MOVEMENT IN CYPRUS

**Abstract author(s):** Wink, Sarah (University of Glasgow)

**Abstract format:** Oral

This paper analyses social change from the Hellenistic to Early Byzantine periods of Cyprus through the analysis of changing ritual movement patterns and use of space. This period covers Cyprus’ transition from Pagan to Christian, several changes in ruling authority and dramatic events that include earthquakes and Arab raids. These changes have important consequences on the use of city-space, sacred space and the associated movement between them. Analysis of ritual movement throughout this period will address how changing movement patterns are affected by both the sacred and the secular. This will provide insight into how people respond to social change through their devotional movement patterns within a complex web of interacting influences working for or against the change. Kourion, Paphos, Salamis and Amathus are employed as case studies in this paper as they demonstrate significant change and continuity throughout this period associated with changing secular and sacred circumstances. Movement patterns considered here include movement to and within the place of worship as how religious space is organised provides important insights into social and cultural norms.

PREHISTORIC INTER-SOCIETAL DYNAMICS ALONG THE ATLANTIC FAÇADE FROM THE NEOLITHIC TO THE IRON AGE

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Higginbottom, Gail (Incipit, Spanish National Research Council) - Carrero-Pazos, Miguel (Institute of Archaeology, UCL)

**Format:** Session with keynote presentation and discussion

In addition to sharing a common environmental background, the communities that were linked by the sea along the Atlantic Façade have repeatedly shared cultural phenomena for more than several millennia. The location of the Atlantic regions as a limit towards the vast Ocean was a vector for developing a strong social identity(ies), an anchor for long-distance connections and the circulation of ideas, innovations and people that started in prehistory. Throughout our focal period, communities became sedentary. Tied to new and old ancestral landscapes, people established local and regional traditions in monument architecture, with certain groups using idiosyncratic changes through a variety of material culture and behavioural forms to express social and political identity.

This session aims to focus on researches and projects along the Atlantic Façade that help uncover possible inter-societal relationships along this expanse. Papers can be regional or local case-studies related to maritime and terrestrial movement, social networks, environmental connections (place, landscape, territory), ritual experiences, cultural practices, material creations and so forth. In this way, papers maybe comparative themselves or they may contain results that can be used for future comparative analyses. Specifically, we would like to see papers coming from a variety of backgrounds and methodological approaches in order that this session can unite studies that contribute towards a greater understanding of this region of western Europe. These include: excavation results to computer modelling and archaeogenetic approaches to landscape archaeology, especially interdisciplinary.

We invite presenters with future projects or ideas as well as those already begun or completed. Together these studies will enable this session to foster future investigations and relationships with emerging research synergies between contributors and participants. With such things in mind, we will look to publishing this session and co-ordinating a yearly session connected within this dynamic geographical region.

ABSTRACTS:

BOYNE TO BRODGAR, AND BEYOND: THE COMPLEX CONNECTIONS OF THE NEOLITHIC MONUMENT BUILDERS IN BRITAIN AND IRELAND

**Abstract author(s):** Sheridan, Alison (Dept. Scottish History & Archaeology, National Museums Scotland)

**Abstract format:** Oral

Similarities between the Neolithic monuments found in different parts of Britain and Ireland, and with some Continental monuments - especially along the Atlantic facade - have long been recognised, and advances in dating, DNA, isotope analysis etc are enabling us to create a rich and nuanced narrative of the connections between the builders. This presentation summarises the main aspects of this changing pattern of connectedness over the period c 4100-2800 BC, and discusses the different social dynamics that are responsible for these connections. The earliest connection arises from the initial process of colonisation by farmers from Brittany, Normandy and Nord-Pas de Calais-Picardie to different parts of Britain and Ireland, which brought both megalithic and non-megalithic traditions. Connections between the subsequent regional trajectories of monument ‘evolution’, and the reasons for these connections, are then presented, with the role of what Mary Helms has termed ‘cosmological acquisition’ being a major factor behind the sharing of aspects of monument design between c. 3200 BC and c. 2800 BC. The presentation will end with a critique of other models that have been proposed, in recent years, to account for apparent similarities in monument forms between Britain and Ireland and the Continent, and it will highlight outstanding questions which the Boyne to Brodgar research initiative seeks to address.

INVESTIGATING A PORTAL DOLMAN: TRETHEVY QUOIT A CORNISH MEGALITHIC TOMB IN A SHARED SEA

**Abstract author(s):** Jones, Andy (Cornwall Archaeological Unit)

**Abstract format:** Oral

Early Neolithic portal dolmens are located around the Irish Sea towards the northern end of the Atlantic façade, with notable concentrations in Ireland, west Wales and Cornwall. Their distinct form comprising jamb stones, a doorstone and a spectacular capstone set at a ‘jaunty’ angle make them one of the most distinctive megalithic monument type in the repertoire of chambered tombs and stone settings erected in the period between circa 3800-3500 cal BC.

Trethevy Quoit is one of the best preserved Early Neolithic portal dolmens both in Cornwall and in the British Isles as a whole. Its erection reveals a knowledge of widely held traditions, as indeed do the building techniques which had no parallel in the local Mesolithic. Its construction, given the range of other megalithic structures, also represents a deliberate choice of architecture and a desire to materialize a particular monument form.

Trethevy Quoit does not, however, just represent the process of replication of the portal dolman form, but rather embodies choices made by community who built it. These decisions include the place that it was erected, and the materials which comprise it. Inves-

tigations at Trethevy Quoit in 2019 revealed a low cairn or platform comprised of deliberately fragmented pieces of green stones, brought to the site in large quantities from a local source. By contrast, the granite slabs forming the chamber of the quoit, suggests that they were from the same rocky outcrop and had been transported from the Bodmin Moor 1.5 kilometres to the north.

This contribution will consider Trethevy Quoit as a designed monument which expresses both local choices and long distance connections of the community who built it.

3 REGIONAL IDENTITIES AND CULTURAL VARIATION IN THE SOUTH NORWEGIAN NEOLITHIC (CA. 4000–1700 BC)

**Abstract author(s):** Olsen, Dag Erik (Museum of Cultural History, University of Oslo)

**Abstract format:** Oral

At the onset of the Neolithic, the people in South Norway were well-adapted hunter-gatherer-fishers with distinct differences in settlement patterns and material culture between western and southeastern groups. This is due to adaptations to unique natural and climatic regional variations and to participation in different cultural networks. The regional variation became even more pronounced after 4000 BC with the spread of the Funnel Beaker Culture (TRB) into South Norway. The southeastern coastal groups became integrated in this network reflected by the presence of imported pottery and polished flint axes. In contrast, this new cultural network did not have any major impact on the western Norwegian societies, where novel local technologies became important instead. This is interpreted as a choice in order to preserve the existing social traditions and also reflects the degree of contact with groups from eastern Norway. One area of possible direct contact between people from the two regions is the high mountains of Hardangervidda and Nordfjella where seasonal hunting for reindeer has a long tradition. Here, distinct regional technological traits indicate a low presence of western groups while the majority of activity can be related to eastern Norwegian coastal and inland groups. This changed after ca. 2800 BC with a more prominent western Norwegian presence and led to more contact and interaction between different cultural groups. This coincides with a marked cultural change in western Norway integrating the region to southern Scandinavian networks via eastern Norway. This paper aims to discuss how various groups developed distinctive social traditions that changed to various degree partly related to fluctuating participation in networks where cultural knowledge was transferred. This also opens for discussing how new ideas was implemented or integrated into existing social structures as reflected by the material culture found at the settlement sites.

4 THE TRANSMISSION OF CERTAIN ARCHITECTURAL ELEMENTS DURING THE EARLY NEOLITHIC (LBK)

**Abstract author(s):** Minnich, Alexander (Universität Wien)

**Abstract format:** Oral

The transfer on of a certain architectural knowledge can be understood as one of the cornerstones of civilizations or cultures and contributes just as much to the self-image of these, such as a common belief, value concept or material culture. Much is already known about the tradition of building knowledge in the Middle Ages, but not much about the transfer of knowledge in the Neolithic, in particular for the Linear Pottery Culture (LBK). The relatively rapid expansion of this culture would not have been possible if there had not been a common basic idea of what a building should look like and how certain interior spaces should be designed. The areas between two adjacent transverse rows play an important role here. The distance between two transverse rows determines the size of the respective interior. The combination of certain rooms of the same size, which can rightly be called modules due to their architectural design, creates interior surfaces that can be combined with one another as required. By omitting a transverse row, a larger interior can be created, for example, which can be referred to as the central room of a long house. When comparing these modules across regions, it was noticeable that similar or equally large interior surfaces or rooms were found in houses throughout the entire distribution area. The study presented here is intended to provide an insight into the architectural ideas and solutions in the Early Neolithic on the basis of selected case studies.

5 INTER-SOCIETAL DYNAMICS ALONG THE ATLANTIC FAÇADE - DOLMENS OF GALICIA AND WESTERN BRITAIN

**Abstract author(s):** Higginbottom, Gail - Gonzalez-Garcia, César - Vilas-Estévez, Benito (El Instituto de Ciencias del Patrimonio - Incipit, CSIC) - Carrero-Pazos, Miguel (University College London)

**Abstract format:** Oral

‘Analysis of Neolithic spatiality at the scale of the European Atlantic Façade remains a difficult task ... the different research traditions in different parts of western Europe have resulted in disparate approaches to material culture, landscape, space and their interpretation’ (Gianotti et al. 2011: 392). By incorporating the uniquely combined cultural indicators of landscapes, megaliths, skylines, skyscapes and astronomy, and the use of bespoke-software as well as more standard forms of statistical analyses, this novel project introduces a globally applicable method to unite research areas across the Façade, thereby resolving such disparate methodological applications. Whilst last year’s presentation concentrated on the early results of our work on Iberian landscapes, in particular Costa de Morte, we now broaden our focus to south-west Britain. This paper, then, will briefly explain the methods applied to dolmen landscapes and sky-scapes in Iberia and Britain, and reveal whether or not Neolithic ideologies, not just architectural rituals, made it to the west coast of Britain from the ‘other side’.

6 COMPARATIVE MODELS OF MEGALITHIC LANDSCAPES IN NEOLITHIC ATLANTIC EUROPE. AN OUTLINE OF THE “MEGASCAPES” PROJECT

**Abstract author(s):** Carrero-Pazos, Miguel (UCL Institute of Archaeology)

**Abstract format:** Oral

The idea that Europe’s Atlantic façade shares elements of a common culture rooted deep in prehistory has long fascinated geographers and archaeologists, and finds expression in modern political organisations such as the Atlantic Arc Commission. The MegaScapes project will use the latest statistical and quantitative methods to examine whether the explosion of megalithic construction across Europe’s Atlantic façade between 5000-2500 BC (and especially 4500-3500 BC) provides evidence of a shared understanding across distant regions of the Atlantic European seaboard as long ago as the Neolithic. It will undertake a comparative study of four important micro-regions of megalithic construction spanning the United Kingdom, Ireland, France and Spain, which will use advances in computational and spatial statistical modelling to analyse spatio-temporal patterns in the arrangement of megalithic monuments, and their possible meaning in a wider landscape context. The latter will be inferred by rigorously investigating regularities in the geographical placement of megaliths, trends in their visibility, their association with pathways and their relation with the lived environment such as settlement and land use. Ultimately the core aim of MegaScapes is to investigate whether the spatial meaning of Neolithic megalithic architecture was regionally variable, or whether it was indeed shared along the Atlantic European seaboard.

7 HEATHLANDS AS INTERSPECIES, INTER-SOCIETAL LANDSCAPES OF THE ATLANTIC FAÇADE

**Abstract author(s):** Løvschal, Mette (Aarhus University; Moesgaard Museum)

**Abstract format:** Oral

Atlantic heathlands were once one of the most extensive open landscapes existing across Northern Europe. They are most frequently defined in biological terms as open, treeless landscapes, dominated by evergreen sclerophyllous plants, and thriving on sandy, nutrient-poor soils. Heather connects large stretches of landscapes above ground (Calluna canopy) and below ground (rhizomes and ericoid mycorrhiza); as well as connecting its accompanying (non)human others who, in turn, ensure its rejuvenation by e.g. systematic burning, turf cutting and grazing. However, although they are frequently portrayed as disowned, disposed and degraded landscapes, the deep-time history of heathlands is one of incredible interspecies complexity, leading to exceptional economic infrastructures, funerary complexes and heath-bound traditions. These deeply integrated ecocultural Atlantic heathlands once formed a connected but somewhat patchy belt along the European west coast spanning from Portugal to the Netherlands, Britain and Ireland, Scandinavia and the steppes of Ukraine in the east and up to Lofoten in northern Norway. At their greatest extent, in the early 19th century AD, they covered millions of hectares, whereas today only a small percentage remains. This poses an intriguing question of what drove and linked the earliest human-driven expansions of heathland-associated grazing regimes and their sometimes incredibly deep-time existence. This paper presents a series of interim results from the newly commenced ERC project: ‘Anthropogenic heathlands: The Social Organization of Super-Resilient Past Human Ecosystems [ANTHEA]’, including new paleoecological and palynological evidence and landscape organisation modelling. These analyses shed new light on how particular landscape-bound practices of resurgence and extraction-oriented disturbances emerge, entangle and institutionalise. Practices that bind people to landscapes and landscapes to people, connecting humans, plants and animals across incredible distances and timespans. As a consequence, I will propose that both the extensive geographical range and deep-time success of the Atlantic heathlands were an interspecies, inter-societal achievement.

389 FROM COAST TO COAST – CURRENT ARCHAEOLOGICAL RESEARCH ON CULTURAL EXCHANGE ALONG AND ACROSS THE BALTIC SEA

**Theme:** 6. Material culture studies and societies

**Organisers:** Jahn, Christoph (Center for Baltic and Scandinavian Archaeology Schleswig) - Cieśliński, Adam - Wadył, Sławomir (University of Warsaw) - Shiroukhov, Roman - Sirkin, Annika (Center for Baltic and Scandinavian Archaeology Schleswig)

**Format:** Regular session

The Baltic Sea is a connecting environment for trade, migration and cultural exchange in prehistoric and historic times and enables long distance trade from modern Scandinavia at the northern coast of the Baltic Sea to the southern coast: the Baltic States, the Kaliningrad area, Poland and Germany. The reception of archaeological research in this area is still very much influenced by the political events of the 20th century, when the Baltic Sea was rather an insurmountable border than a connection between the neighboring states along the northern and southern shores of the Baltic Sea.

This session intends to be a kind of overview on the recent and current research, studies and research projects related to the cultural interaction between different areas along and across the Baltic Sea during the Bronze Age, Iron Age, Roman and Migration Period, Viking Age and the Middle Ages. We are looking for examples of archaeological data that illustrate social and economic processes, cultural exchange, intercultural and cross-cultural relations of different societies around the Baltic Sea. How much Scandinavian influence can be found at the other Baltic societies? What kind of Baltic, Slavic, Finno-Ugric, etc. material came to Scandinavia? What are the connections amongst the cultures at the southern or eastern coast of the Baltic Sea? Can we identify migration, demographic changes or group identity by international and interdisciplinary exchange of data? We are interested in new research projects

and results of studies on the widely understood topic of cultural exchange as well as presentations on methodology, chronology and typology of archaeological sites and artefacts of the Baltic Sea region.

ABSTRACTS:

**PRUSSIA MUSEUM DIGITAL. A NEW RESOURCE FOR RESEARCH ON ARCHAEOLOGY IN FORMER EAST PRUSSIA**

**Abstract author(s):** Eilbracht, Heidemarie (Museum für Vor- und Frühgeschichte Berlin)

**Abstract format:** Oral

Since 2012, the project “Continuity of Research and Research of Continuity. Basic Research on Iron Age Settlement Archaeology in the Baltic Region” has been working on the scientific processing of archaeological sources from the former Prussia Museum in Königsberg/Ostpreußen. Until the Second World War, the Prussia Museum owned one of the most important and largest collections of prehistory in the southern part of the Baltic region. In the post-war period, these important holdings fell into oblivion. They were considered lost or destroyed until big parts were rediscovered decades later through fortunate circumstances, among others in Berlin and Kaliningrad. Since then, they have been scientifically treated in several projects with the aim of making these documents and finds of about 150 years of archaeological activities in the region usable for modern research again.

Within the context of “Continuity of Research and Research of Continuity”, the database “prussia museum digital” was developed as an important digital tool for the presentation as well as for the scientific interpretation and the long-term preservation of archaeological sources from former East Prussia. It currently offers information on more than 2,700 archaeological sites. It presents about 2,200 volumes of so-called site files with excavation reports, find notes, drawings and photos and, last but not least, more than 18,000 archaeological finds. Step by step, the richness of the archaeological remains is coming to light again, highlighting the role that the region has played in exchanges and contacts with its neighbours throughout the ages. The database has been made available to the specialist community since 2021. The lecture will give an insight into the concept and further perspectives and present selected archaeological results within the database.
- 2

**BORNHOLM - THE ISLAND IN THE MIDDLE. SOCIETIES, CONTACTS AND ALLIANCE SYSTEMS ON THE THRESHOLD OF HISTORY**

**Abstract author(s):** Trolle, Tine (National Museum of Denmark)

**Abstract format:** Oral

Based on the archaeological material from Bornholm's largest cemetery of cremation graves, Store Frigård, the purpose of the project is to shed light on societies, contacts and alliance systems in the Baltic Sea region in the Early Iron Age (500 BC - 400 AD).

With its central geographical location in the middle of the Baltic Sea, Bornholm has always been an obvious link between the Continent and Scandinavia. This is especially true in the Early Iron Age, where the island's communities were in close contact with the northern German and Polish as well as the southern Scandinavian areas, especially Öland and Gotland. The cemetery of Store Frigård contains 1250 graves and has been used for a continuous period of almost 900 years.

The project, which is planned in the time frame 2021-2024, is anchored in a Danish-Norwegian-Swedish collaboration supplemented by the participation of a large number of researchers from Denmark and Poland.

The project and its perspectives are presented at the session.
- 3

**TRACES OF A MIGRATION FROM SCANDINAVIA? THE ROMAN PERIOD CEMETERIES WITH STONE CIRCLES ON THE SOUTHERN BALTIC COASTLAND**

**Abstract author(s):** Cieslinski, Adam (University of Warsaw / Faculty of Archaeology)

**Abstract format:** Oral

One of the most interesting features of the Wielbark culture, the most important archaeological unit in northern Poland in the early Roman Period, is a relatively small group of cemeteries with stone circles. In historical times, these sites were being destroyed on a large scale to obtain stone for construction purposes. Until today, only a few surely confirmed sites of this type have survived in Pomerania, of which only a few have been excavated.

The tradition of building stone circles was unfamiliar to the communities living in the areas between the Oder and the Vistula before the Roman Period. Moreover, all cemeteries with stone circles seem to have been established in previously unsettled territories, unlike most of the Wielbark culture cemeteries from the early phase, which had apparently been used without interruption from the Pre-Roman Period. For this reason, it is believed that stone circles were built by the communities that had come from Scandinavia, where structures of this type date back to the Bronze Age. Stone circles are quite commonly associated with the migration of the Germanic tribe of Goths, described in written sources. According to an account by Jordanes from the first half of the 6th century, which he based on Cassiodorus (Getica IV, 25 ,26), the Goths came from the island of Scandza, i.e., from Scandinavia. In the specialist literature, the thesis of the Scandinavian origin of the Goths was either accepted, very often without critical analysis, or completely rejected - in this second case Jordanes's tradition was regarded as a topos.

The paper will present the state of research and discussion on the genesis and interpretation of stone circles in Poland, with particular emphasis on the possibility of linking this phenomenon with the information about the migrating Goths found in written sources.

**“STONES AND CIRCLES”: TO THE STUDY OF THE BURIAL RITE OF THE SOUTHEASTERN BALTIC IN THE 1ST CENTURY AD**

**Abstract author(s):** Khomiakova, Olga (Institute of Archaeology of RAS, Moscow) - Skhodnov, Ivan (NIC Pribaltijskaja Archaeologia, Kaliningrad) - Kleshchenko, Ekaterina (Institute of Archaeology of RAS, Moscow)

**Abstract format:** Oral

At the beginning of Common Era, the cultures of the coastal zone of the Southeastern Baltic, associated with the Aestians of Tacitus, underwent changes in the funeral rite. Collective burials are being replaced by individual ones, characterized of corpses and cremations, accompanied with personal ornaments in Provincial-Roman style and covered with concentric stone structures. Despite an extensive database of burials of the most representative Aestian culture – Sambian-Natangian (SNC) of Kaliningrad region, the origin of their main characters is still not clear. A relatively small number of complexes of this period are known mainly from archival data. The presentation shows new data on the burial rite of the SNC, obtained as a result of recent work on its sites in the Pregolya Valley, from where the earliest finds of ornaments in Celtic-Roman style originate, indicating the beginning of the formation of the Roman period culture. Using modern research methods, data have been obtained on individual burials (cremations in urns and without) dated to the Central European phases B1/B2 (middle - third quarter of the 1st century AD) with stone circles and causeways. The bioarchaeological aspect of such burials is considered for the first time. Analogies in the funeral rite of the south of the Scandinavian Peninsula, the islands of Gotladn, Öland and Bornholm, as well as in the burial grounds of the lower reaches of the Vistula, again raise the question - who were the ancient Aestians?
- 5

**AMBER FINDS FROM 1ST-7TH CENT. AD IN NORTHERN EUROPE – NEW STUDIES ON DISTRIBUTION AND USE OF A SPECIAL MATERIAL**

**Abstract author(s):** Offermann, Karl Johann (Center for Baltic and Scandinavian Archaeology Schleswig)

**Abstract format:** Oral

Amber from different periods of human history has always been in the interest of archaeological research. However, for Scandinavia and Northern Germany no comprehensive studies on amber in the period from 1st to 7th century AD have been carried out so far.

Apart from few regional studies and investigations on specific amber bead types, there is a lack of analyses that takes the overall perspective in the area. Therefore, an overall survey of amber finds from various contexts is now presented for the first time. Besides the large number of grave finds, there are also amber finds from settlements, sacrificial bogs or hoards, which have to be evaluated differently. Thus, on the basis of amber different value concepts and exchange mechanisms at that time can be deduced and investigated.

Especially with regard to the origin of the raw material only theories are available so far. Besides the coasts of Southern Scandinavia, such as the North Sea coast of Jutland, the south/southeast coast of the Baltic Sea is in focus as well, like the territory of the former East Prussia. This area was known for its amber wealth already in the 1st mill. AD – the largest deposit in Europe. So, it is quite possible that amber was not only traded/exchanged from here to Central and Southern Europe, but also found its way to Northern Europe, which would provide further evidence of the relationship between these regions.

This offers the opportunity to trace the development of amber use and distribution in the first half of the 1st mill. AD in Northern Europe and beyond – away from the well-known “Amber Roads”.

**GLASS BEADS OF LATE ROMAN PERIOD FROM WEST LITHUANIA AS INDICATORS OF COMMUNICATION ACROSS THE BALTIC SEA**

**Abstract author(s):** Banytė Rovell, Rasa (Lithuanian Institute of History, Vilnius)

**Abstract format:** Oral

At first sight glass beads represent a database of finds which was formed by the process of chaotic inflow and by the luck of archaeological investigations. M. Mączyńska remarked that it is difficult to find necklaces of identical composition. Nevertheless some compositions of beads are typical for particular cultural areas. This tendency testifies that at the same time different collections of beads were brought from Roman provinces to particular regions (M. Mączyńska 1997, 103). Analysis of West Lithuanian material proved that the first considerable distribution of imported glass beads is noticable in burials from mature phase B2. The same horizon of rich glass necklaces is recorded also in other areas of West Balts dwelling in South-Eastern – Eastern Baltic. The diversity and number of glass beads became very modest during phase B2/C1-C1a in West Lithuanian areas. The new inflow of glass beads is remarkable in the material of burials which belong to the second half of phase C1b – phase C2. Many types of beads from this time also were typical for Southern Scandinavia. It seems that similar collections of glass beads circulated in various Baltic Sea regions. Glass beads of the Late Roman Period should be brought to West Lithuania via sea routes. They are another confirmation that various Baltic coastlands shared the same goods especially such as glass beads. The distribution of similar sets of beads support the thesis that such luxurious finds typical of Southern-South-western regions of the Baltic Sea as a bronze-silver gilted omega

buckle from Jogučiai Cemetery or the silver-gilt detail of a rosette brooch from Baitai cemetery did not find their way to Lithuanian Coastland by accident.

7 “GOTLANDIC” IMITATIONS OF LATE ROMAN SOLIDI – LOCAL CUSTOM OR BROADER PHENOMENON?

**Abstract author(s):** Zapolska, Anna (Faculty of Archaeology, University of Warsaw)

**Abstract format:** Oral

Within the finds of hoards of late Roman and early Byzantine solidi, there is a small group of barbaric coins which are impossible to link to any known existing mint in the Roman Empire or to any of the barbarian kingdoms established on its ruins. These coins have some common elements (e.g. degenerated legends, obverses and reverses taken from different coins), and a few of them share common dies which can be identified on Gotland and Bornholm, and in Pomerania. All of them can be overall dated to late 5th and 6th. In this paper, these imitations will be briefly presented and as well as a typological and chronological arrangement.

Their interregional connections around the Baltic mirrored by the circulation of the gold objects will also be considered. In the end the differences in perceiving and treating the gold objects (coins, one-sided bracteats, and jewellery) by societies living in the Baltic region.

8 GOLD LADY AND TROLLS. THE ARCHAEOLOGICAL SITE AT SMØRENGE ON BORNHOLM AS INSIGHT INTO INTERREGIONAL CONTACTS IN THE BALTIC REGION

**Abstract author(s):** Czonszke, Karolina (University of Gdańsk; Archaeological Museum in Gdańsk) - Świątkowski, Bartosz (University of Gdańsk)

**Abstract format:** Oral

The heritage of the Baltic Sea region is unique and has many different faces. The flow of people and ideas here throughout the past were complex and multifaceted. Not least, various Baltic societies were linked through rituals, rites, and religious beliefs. These elements were also diverse and changed across time and space. Additionally, ceremonies contained significant meanings and played important roles in explaining the world, the annual cycles, and everyday life. They also had a binding effect on life after death. The ways in which rituals and rites were conducted and performed as well as the time and spaces in which they occurred also contain essential meanings.

These phenomena are a reflection of social life and the scale and form of contacts that a given community maintained in the past. In the case of the Baltic Sea region, the interregional character of these contacts is especially visible.

However, capturing these subtle nuances in archaeological material is extremely difficult but, at the same time, a fascinating avenue for archaeological research.

Research on the Danish island of Bornholm will serve as an important case study for examining the rituals' forms and meanings and their reflection in social life. They also contribute to discussions about contacts in the Baltic Sea region. For instance, the archaeological site in Smørenge revealed remains connected to belief-structures from the Vendel period. At this unusual place, archaeologists also found the remains of a spring with a rich collection of unique artefacts like gold votive foils, weapons, and glass beads, among other materials.

The form and meanings of the rituals behind these materials are still ambiguous, but they can help shed a little light on the ethereal world of beliefs and rituals of past inhabitants of the Baltic Sea region.

9 LANDSCAPE OF THE GODS – A PROJECT ABOUT SACRAL TOPOGRAPHY AND RELIGIOUS NETWORKS OF IRON AGE BORNHOLM

**Abstract author(s):** Albris, Sofie Laurine (National Museum of Denmark)

**Abstract format:** Oral

This paper presents a new research project about the sacral landscapes and religious networks of Iron Age Bornholm. This island in the Baltic Sea has an exceptional density of well-documented archaeological locations, offering a unique possibility to investigate pre-Christian sacral topography in detail. Several sites on Bornholm have evidence of pre-Christian cultic activity and a large amount of gold foil figurines reveal elite networks throughout Scandinavia. In the Iron Age, the island was a hub of trade and contacts in the Baltic Sea area.

The project runs from August 2021 and is a cooperation between the National Museum in Denmark and Bornholms Museum, funded by the Carlsberg Foundation. It consists of a detailed interdisciplinary analysis of place names, archaeology and landscape related to pre-Christian religion on Bornholm. These materials are brought together to form a comprehensive study of religious activities and places on the island. Based on these investigations, the project uncovers interplays between social organisation and sacral topography and explores the role of these interplays in developments at local and supra-regional levels as well as relations between levels of the cult in the topographical and social landscape. The project will thus seek to identify dynamics behind religious change and the position of Bornholm in pan-Scandinavian religious networks.

10 THE ANTHROPOMORPHIC FIGURINE’S HEAD FROM HAITHABU - A VIKING AGE GAMING PIECE?

**Abstract author(s):** Andersen, Anna-Theres (Institute for Prehistoric and Historic Archaeology, Kiel University)

**Abstract format:** Oral

In 2018 an anthropomorphic amber-figurine’s head from a private archaeological collection was shown to the Schleswig-Holstein State Museums Foundation Schloss Gottorf in Schleswig (Germany). Both the first impression of the figurine and the statement of the collector declaring the object was originally found close to the UNESCO world heritage Haithabu led to the assumption of a Viking Age artefact. Due to new evidence the presented object originally has been found at an excavation in Haithabu which took place in 1936 but never reached the museum.

This paper compares the head of the figurine with other archaeological finds from this old trading place – especially the amber gaming pieces are considered. In this context different interpretations will be presented and discussed.

However, amber seems to be a valued material for gaming pieces due to Scandinavian comparative finds. Not only the size but also the design of gaming pieces suggests a significant resemblance in the understanding of board games in Viking Age Scandinavia.

11 FROM SCANDINAVIA THROUGH THE PIAST ROYAL COURT TO POMERANIA. AN AMAZING STORY OF MEN BURIED IN CHAMBER GRAVES IN CIEPŁE

**Abstract author(s):** Wadył, Sławomir (Faculty of Archaeology, University of Warsaw)

**Abstract format:** Oral

The story of Ciepłe begun in 1900. Chance discovery of an outstanding grave that was thought to be a Viking burial excited a great deal of interest. The 21st century has added some new chapters to the history of Ciepłe. Rediscovery of burial ground and further excavations revealed very richly furnished chamber graves.

The Ciepłe cemetery is part of an extensive settlement complex comprising three strongholds, three settlements and two burial grounds. Previous research results indicate that it was founded on the initiative of the first Polish rulers, Mieszko I (c. 960-992) or Bolesław I the Brave (992-1025). Seven chamber graves were unearthed in Ciepłe. These graves were distinctive because they bore witness to an unusual burial rite and because they were remarkably richly furnished, both in comparison with other burials at this cemetery and with other graves of this period on a nationwide scale. Four of them – the ‘founder graves’ in the cemetery’s central, demarcated section –are exceptional. Graves 35, 42, 43 and V are without doubt the most richly furnished burials of the early medieval period ever found in Poland. Similar sets of goods were deposited in each of these graves, consisting of swords, spears, and horse equipment in the form of spurs, stirrups and bits.

The individuals buried in graves 35, 42, 43 and V were probably particularly prestigious. The weapons and horse equipment deposited with them attest to their rank, and possibly their profession. They were probably members of a mounted elite. The origin of those buried at the Ciepłe cemetery is a key question. Genetic studies and strontium isotope analysis have shown that the men buried in these graves were most likely born (or spent their childhoods) in western Scandinavia, probably Denmark. There are some evidences of Polish-Scandinavian political and military alliances.

12 CROSSING WATERS – THE SCANDINAVIAN INFLUENCE ON THE VIKING AGE CEMETERIES OF WISKIAUTEN AND LINKUHNEN AT THE CURONIAN LAGOON

**Abstract author(s):** Jahn, Christoph (Center for Baltic and Scandinavian Archaeology Schleswig)

**Abstract format:** Oral

The cemeteries of Wiskiauten (Mokhovoye) and Linkuhnen (Rzhevskoye) were excavated from the 1870s to the 1930s by archaeologists in the former German province of East Prussia. Both archaeological sites sparked an intense discussion about the Scandinavian presence, and cultural influences on the southern coast of the Baltic Sea in the Viking Age. High quality Scandinavian jewelry in the grave mounds of Wiskiauten and the large number of ULFBERHT-swords from Linkuhnen were extraordinary finds among the Baltic tribes on the Sambia peninsular and the Curonian Lagoon and indicated different kinds of cultural contacts across the Baltic Sea. Due to the Second World War, the excavation results were never properly published, and during the Cold War the archaeological objects and excavation diaries from Wiskiauten and Linkuhnen were considered lost, so that the archaeology of East Prussia was more or less forgotten. However, it turned out in the 1990s, that finds and archives from Prussia-collection in Königsberg (Kaliningrad) have partly survived in Berlin (Germany), Olsztyn (Poland) and Kaliningrad (Russia), and therefore the reconstruction of former excavation results was possible.

The revaluation of the cemetery of Linkuhnen was finished and published in 2019, the reconstruction of pre-war research in Wiskiauten is an ongoing publication project at the ZBSA in Schleswig. The comprehensive analysis of the available archival information sheds a new light on the wide range of grave goods and funeral rites in Linkuhnen and Wiskiauten. This presentation discusses finds and grave features from both sites, which indicate different ways of cultural interactions between Scandinavians and Balts across the Baltic Sea in the Viking Age. The reconstruction of pre-war research is essential for the understanding of modern excavation in the Wiskiauten area (see abstract of Annika Sirkin).

THE MISSING TRADING PORT OF WISKIAUTEN/MOKHOVOYE ON THE SAMBIA PENINSULA – A FINAL ASSESSMENT ON THE ARCHAEOLOGICAL INVESTIGATIONS 2005–2011

**Abstract author(s):** Sirkin, Annika (Centre for Baltic and Scandinavian Archaeology, Schleswig)

**Abstract format:** Oral

The interpretation of the rich Early Medieval burials in the burial ground of Wiskiauten/Mokhovoye (Kaliningrad region, Russia) as of Scandinavian and Prussian origin (see abstract of C. Jahn) raised the question of a nearby Baltic trading port at the Curonian Lagoon of the scale of Truso, Hedeby or Birka. In the 20th century, the search for this marketplace was not successful. Only a German-Russian field study carried out from 2005 to 2011 under the direction of Dr Timo Ibsen was able to document numerous settlement traces. The study comprised an extensive geophysical survey, excavations and a preliminary geological survey within a radius of around 1 km from the burial ground of Wiskiauten. In addition, 14C-dating, archaeozoological, and archaeobotanical analyses were carried out.

In the author´s dissertation, completed in 2020, a final assessment of the enormous data from this interdisciplinary study was made. Four settlement areas could be identified that acted as satellites for the sought-after trading port. For the first time, Prussian house structures could be reconstructed. A large number of small finds suggest influence and trade with Scandinavians, Slaves, Rus´, other Balts and perhaps even Finno-Ugrians. Traces of amber bead production and metalwork were found. Intensive 14C-dating revealed an astonishingly broad chronology of the settlements, which gives insight in the development of local settlement activities, with a special focus on the time of the arrival of the Scandinavian settlers. Furthermore, a new interpretation of geological data of the variable coastal landscape could provide an explanation as to why the trading port has not yet been found, but where it might be.

FROM THE BALTIC TO THE BLACK SEA. IN SEARCH OF THE ORIGIN OF OSTRIV CEMETERY MIGRANTS (UKRAINE)

**Abstract author(s):** Shiroukhov, Roman (Centre for Baltic and Scandinavian Archaeology - ZBSA) - Baranov, Vyacheslav - Ivakin, Vsevolod - Kozak, Oleksandra (Institute of Archaeology National academy of science of Ukraine)

**Abstract format:** Oral

The Late Viking Age cemetery Ostriv was discovered by an Institute of Archaeology of the National Academy of Science of Ukraine (IA NASU) team in 2017, approximately 100 km from Kyiv in the Porossya region. To date, 82 inhumation graves have been excavated in an area of 1500 m2. Most of the artefacts from Ostriv are uncommon in Ukraine, but are frequently found in the East Baltic region.

The pilot project “Baltic migrants in Kievan Rus” is implemented by IA NASU and ZBSA together with CAU laboratories and anthropologists from Latvia and Lithuania in 2019-2020. The work started at the point of analysis of morphological features of Ostriv and East Baltic archaeological artefacts and burial rite. Complex AMS 14C-dating, stable isotopes, aDNA and non-destructive metal analysis was provided in frames of the pilot-study.

Ostriv cemetery combines the local Kievan Rus´ and East Baltic region funerary and typo-chronological features. According to the AMS 14C datind two phases can be distinguished: phase 1 (980-1020 AD) correspond to the first wave of migrants and associated with time of reign of Vladimir; phase 2 of (1010-1040 AD) correspond to the short time of Svyatopolk and Yaroslav the Wise rivalry and the long reign of Yaroslav.

Skeletal remains anthropological research demonstrate the Ostriv population as rather young with a low adaptation level. The similarity of the AMS 14C dating results together with δ15N and δ13C isotopes ratios and the typo-chronological background of Ostriv and East Baltic individuals may indicate the synchronous origin of both two populations sites and their similar diets. The first results of the genetic analysis show the external origin of the Ostriv individuals, placing them closer to the Baltics and Scandinavia. At the preliminary level of research, the people of Ostriv are considered as East Baltic region incomers.

YATVINGIAN ‘VALLEY OF THE KINGS’ AT THE SZCZEBERKA RIVER

**Abstract author(s):** Nowakiewicz, Tomasz - Rembecki, Dawid - Lewoc, Iwona (University of Warsaw) - Miłek, Sławomir (Ab Terra Foundation)

**Abstract format:** Oral

The year 2020 brought not only pandemic restrictions to most of the aspects of life activity but also - in contrast - a series of discoveries changing the image of Balt archeology, at least in its regional frames, limited to the southern part of the territories of the Balts (within Polish borders).

In a hard-to-reach area inside the former tribal land Yatvingia/Sudovia (in the neighborhood of so-called ‘Sacred Place’ at the Rospuda River), a group of closely located early medieval cremation cemeteries with above-standard rich equipment was registered. They form a distinct burial zone that functioned there in the last phase of tribal Yatvingia (12-13th century). Its recognition is a huge challenge in a few various research areas: methodological (a stratified cemetery with features similar to Aschenplätze but far from typical examples of that kind of necropolis), material (the largest collection of the Balt artifacts so far in the history of Polish archaeology!) and interpretative (related to the settlement topography, forms of the burial rite, Yatvingian-Prussian and Yatvingian-Lithuanian relations, etc.).

The paper presents the characteristics of this phenomenon, the current state of research, the first conclusions, and a list of the questions and research postulates.

SOMETHING OLD AND SOMETHING BORROWED: DRESS IN NORTH-ESTONIA IN THE TURN OF THE 12TH-13TH CENTURIES

**Abstract author(s):** Rammo, Riina (Department of Archaeology, University of Tartu)

**Abstract format:** Oral

Clothing research in the eastern Baltic region often seems to follow the modern state borders. This state-of-the-art is understandable because many special features exist, for example, in the ornaments and other clothing-related finds in different areas around the Baltic Sea. The paper’s starting point is the clothing habits in present-day North-Estonia in the turn of the 12th and 13th centuries. The grave finds of the period give an idea of proper appearance and clothing habits adopted by a group of people in a particular area and period. The words ‘traditional’ and ‘local’ describe the outfit based on this source material in many aspects, and finding regionality has also been the focus of previous studies. The presentation aims to look at these clothing habits in the context of fashions in the wider Baltic region, as the sea provided opportunities for communication and interaction with different people and places. Did these contacts somehow affect the choices made by dressing? If the focus will be on finding similarities in clothing-related finds instead of emphasizing differences, can they be discovered? How influences from across the sea manifest themselves, for example, for men and women? The presentation will follow certain clothing aspects, such as textiles, special garments, that reveal the communication across the northern Baltic Sea.

CROSS-DISCIPLINARY APPROACHES TO ARCHAEOETHANATOLOGICAL AND TAPHONOMIC ANALYSES OF HUMAN REMAINS

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Camarós, Edgard (IIIPC - Universidad de Cantabria) - Knüsel, Christopher (PACEA - Université de Bordeaux) - Schotsmans, Eline (Centre for Archaeological Science - University of Wollongong)

**Format:** Regular session

Both archaeoethanatological and taphonomic analyses of human remains are emerging fields. Since the 1980s taphonomic analysis of human remains has evolved from an adjunct and secondary interest within archaeology and palaeoanthropology to become a core interest on both archaeological and geological time scales. This change came about through realisation that the context in which remains were found had a profound influence on not only the preservation of them but also permitted researchers to better interpret the processes that contributed to the patterns found in the archaeological and palaeontological record. In essence, this shifted interests from being solely concerned with the biological analysis of remains to a more holistic and systematic approach to consider the contexts in which remains are found to address both biological and social evolutionary questions- from the origin of hominins to the present day. This opened a new scientific agenda in which taphonomic research informs research objectives in bioarchaeology, osteoarchaeology, palaeoanthropology, and palaeontology, and it is the central focus for research interests variously identified as funerary taphonomy, funerary or mortuary archaeology, archaeoethanatology and the archaeology of death, and has also become increasingly important in forensic anthropology and archaeology and medico-legal science, which share an interest in understanding how past physical processes influence the preservation and patterning of human remains. Although there may not be an agreed single definition of taphonomy, there is homogeneity in taphonomic analysis, which shares the idea that modifications of human remains have enormous potential for answering behavioural and environmental research questions about the past. This session welcomes contributions from those with shared interests in fostering cross-disciplinary perspectives. The goal of the session is to develop a collaborative network that will assess the state of these studies, aid the development of new techniques, and identify and disseminate experimental approaches to better address research questions.

ABSTRACTS:

WHAT IS ARCHAEOETHANATOLOGY, AND HOW DOES IT RELATE TO TAPHONOMY?

**Abstract author(s):** Knusel, Christopher (UMR 5199 PACEA, Université de Bordeaux)

**Abstract format:** Oral

Archaeoethanatology is defined as the scientific study of death in all its dimensions, biological, cultural and social (Duday 2012: 62). It focuses on reconstructing the original disposition of the cadaver based on the distribution and state of articulation of the skeletal remains, whether in an archaeological or medico-legal context. It is a method that offers a way to develop greater insight into funerary ritual; it encompasses funerary archaeology, with its emphasis on the grave and its constituents, and the study of human remains. Having developed as part of biological anthropology, at its heart is the active participation of biological anthropologists trained in archaeological methods in the excavation of human remains, with additional detailed recording of the grave and its contents, often involving multiple, incremental plans and observations.

The original terminology and applications of archaeoethantology were solely published in French and in Francophone publication venues. As a consequence, they developed in parallel but in isolation from other approaches to human remains, their archaeological

context, and analysis. This means that archaeothanatological principles and terminology require synthesis with a variety of other existing practices, terms and uses to aid dissemination. Moreover, the relationships between archaeothanatology and bioarchaeology, as well as with archaeological excavation and analysis, in general, and taphonomic studies, in particular, are at the present time unclear. This presentation reviews the basic principles of archaeothanatology, considers its disciplinary place, and broaches some questions surrounding its use in the context of taphonomic studies.

## FROM FLESH TO BONE: BUILDING BRIDGES BETWEEN TAPHONOMY, ARCHAEOETHANATOLOGY AND FORENSIC SCIENCE FOR A BETTER UNDERSTANDING OF MORTUARY PRACTICES

**Abstract author(s):** Schotsmans, Eline (University of Wollongong; University of Bordeaux) - Georges-Zimmerman, Patrice (Institut National de Recherches Archéologiques Préventives - Inrap; Université Toulouse Jean Jaurès) - Ueland, Maiken (University of Technology Sydney) - Dent, Boyd (Red Earth Geosciences Sydney)

**Abstract format:** Oral

Archaeothanatology goes beyond taphonomy and bones. It touches on cultural aspects, funerary practices and their socio-cultural interpretation. However, in order to come to an interpretation, careful observations should first be made in the field. A thorough archaeothanatological analysis cannot be conducted without studying the depositional environment and human decomposition. Therefore, it is important to gather data from burials of known form and context to support these interpretations. Based on experiments at the Australian Facility for Taphonomic Experimental Research (AFTER) and modern cemetery research, this presentation will show that archaeo-anthropologists require understanding of human decomposition, material degradation and factors that influence decay and bone movement. The examples will highlight that human remains should be analysed in their broader depositional context; that experimental research is highly valuable; and that hypotheses and interpretations should be treated with caution. The aim is to emphasise a critical use of terms and methods, and the integration of interdisciplinary approaches such as forensic experiments and modern cemetery studies.

3

## RESULTS AND METHODS OF AN ONGOING EXPERIMENTAL TAPHONOMIC RESEARCH PROGRAM TO IMPROVE THE INTERPRETATION OF HUMAN REMAINS IN (FORENSIC) ARCHAEOLOGY

**Abstract author(s):** Mickleburgh, Hayley (Linnaeus University; Forensic Anthropology Center Texas State University)

**Abstract format:** Oral

Understanding the formation processes of human burials and distinguishing the effects of human modification of the remains and their surroundings from taphonomic processes is key to reconstructing the sequence of events leading to death and burial. This paper discusses the methods and findings of an ongoing experimental forensic taphonomic research program developed to improve the interpretation of human remains in both traditional and forensic archaeological contexts. This inter-disciplinary program aims to advance and develop archaeothanatological methods and models, as well as study the effects of decomposition and diagenesis on the isotopic composition of different body tissues over time, assess the potential of using biomarkers for post-mortem interval and age at death estimation (proteomics), and research changes in the human microbiome throughout decomposition. The program focuses on replication of two distinct medicolegal/archaeological burial contexts - individual depositions and mass graves - in a series of actualistic experiments at the outdoor human decomposition facility associated with the Forensic Anthropology Center at Texas State University (FACTS).

The actualistic experiments have been designed to collect a body of data suitable for both qualitative and quantitative analysis, distinguishing the effects of specific variables, and replication studies in other environments. An important objective of the experiments is to examine two important taphonomic models used in archaeothanatology 1) the sequence of joint disarticulation, and 2) the relation between spatial displacement of bones and primary and secondary open space (voids) in the burial environment. A pipeline of 3D documentation and analysis was developed specifically to study the spatial relation and movement of human remains throughout soft tissue decomposition and skeletal disarticulation, based on photogrammetry, 3D GIS and animation. This presentation describes the results of the research as well as the 3D documentation pipeline, and outlines important avenues for future development and collaboration in this area of research.

4

## AN EXPERIMENTAL TAPHONOMIC STUDY OF HUMAN DECOMPOSITION AND DISARTICULATION IN COFFINS

**Abstract author(s):** Alfsdotter, Clara (Linnaeus University; Bohusläns museum)

**Abstract format:** Oral

Archaeothanatology offers valuable insights into past corpse treatment. The method heavily relies on the relative timing of joint breakdown. Through in situ observations, interpretations of the space and nature of the deposit can be interpreted from skeletal positions.

Experimental (actualistic) studies of human decomposition can inform archaeological knowledge in regard to human taphonomy. This paper discusses results from a human decomposition study conducted at the Forensic Anthropology Center, Texas State University (FACTS). Two willied donated deceased humans were reserved for the study. They were placed in wooden coffins, one below ground, and one with the lid in ground level. The study addresses the general taphonomy of coffin decomposition, as well as the sequence of joint disarticulation and associated factors.

The disarticulation sequence in the continuously monitored coffin diverges from the sequence proposed in in previous archaeothanatological research. Quantitative actualistic studies are needed in order to deduce if a common disarticulation sequence exists. While interpretations relying on a disarticulation sequence based on archaeological findings are discouraged by the current results, they do not conflict with the more general archaeothanatological principles that movement of bones out of anatomical position in general can be a useful indicator for postmortem manipulation or taphonomic processes, and that archaeothanatology is useful in terms of identifying movement out of the original space of the corpse to deduce if the corpse was placed in an open (such as coffin) or closed (directly in sediment) space. However, the process of decomposition and disarticulation is more complex than can be deduced from skeletal remains, and therefore inferences about decomposition from skeletal remains can be misleading.

The results confirm the importance of a holistic understanding of how dead bodies interact with the surroundings, which is paramount for complex reconstructions of archaeological mortuary treatment.

5

## THE USE OF PHYSICOCHEMICAL CHANGES TO ADDRESS THE LATE POSTMORTEM INTERVAL AND UNBURNT AND BURNT BONES

**Abstract author(s):** Vegh, Emese (University of Oxford) - Marquez-Grant, Nicholas (Cranfield University, Defence Academy of the United Kingdom) - Schulting, Rick (University of Oxford)

**Abstract format:** Oral

Chemical profiles of bones undergoing diagenesis can provide information on the early post-depositional changes to the skeleton. The post-depositional environment and treatment of human remains, such as burial, exposure, or burning, can alter bone chemistry. The trace element content of the mineral phase of bone – bioapatite – is susceptible to changes as soon as it is exposed to the depositional environment. This paper aims to utilise alterations in elemental and structural changes in bioapatite to help determine the post-mortem interval (PMI) prior to burning through an experimental taphonomic approach.

Fleshed pig (Sus scrofa, N=25) tibiae were left exposed in a field in Oxfordshire, UK, and collected at 14, 34, 91, 180, 365 day intervals before being burnt in an outdoor fire (≤750 °C bone temperatures). Fresh tibiae (N=10) acted as unburnt and burnt controls. Samples were spatially analysed for major and trace elements by energy wavelength-dispersive spectroscopy (WDS-EMPA) and Fourier Transform Infrared Spectroscopy (FTIR).

Results show a significant linear decrease in K in both unburnt and burnt bones, while Al and Mg increase in unburnt bones through time. Mn shows a non-linear increase at all PMIs upon exposure in the cortical walls of unburnt bones. Na, K, and Ca could potentially assist in estimating the PMI prior to burning. Lowest variations of concentrations were found further from the outer cortical surface. Elements associated with bioapatite (Ca, P) and the extracellular fluids (Na, K) covaried the least. Carbonates (A and B) decreased while crystallinity index increased in unburnt bones during the first 1 year of PMI.

6

## LET’S MAKE A MESS, MAYBE NO ONE WILL NOTICE. IMPACT OF BIOTURBATION ACTIVITY ON THE URN FILL STRATIGRAPHY

**Abstract author(s):** Haluszko, Agata (Archeolodzy.org Foundation; Institute of Archaeology, University of Wrocław) - Kadej, Marcin (Department of Forensic Biology and Entomology, Institute of Environmental Biology, Faculty of Biological Science, University of Wrocław) - Gmyrek, Grzegorz (Usługi Archeologiczne Grzegorz Gmyrek, Kalisz)

**Abstract format:** Oral

The study of prehistoric cremation burials is an interesting subject of research of taphonomic processes occurring directly in the urn fill. Often these processes have a significant impact on the subsequent interpretation of the data, and to a broader extent, on the reconstruction of the funeral rite of the studied society.

Bioturbation activities are particularly difficult to observe in sandy soil on which urnfields were most often established. This type of soil characterized by macroscopic color uniformity, and therefore it is difficult to catch certain taphonomic processes occurring in the fill of the urn. During standard exploration of mechanical layers, it is complicate to observe layers disturbed by rodents, insects, earthworms or plant roots. Computed tomography (CT), which is a non-invasive imaging method, can solve these problems.

The bioarchaeological examination was carried out at the Wtórek cemetery, Greater Poland, Poland. This cemetery is connected with the Lusatian culture’s society which forms as a part of the Urnfield tradition. It is dated from the Late Bronze Age to the Early Iron Age. Of over 200 graves, 20 urns were CT-scanned and postprocessing analyses were conducted. In this way, 3D reconstructions of archaeological artefacts were obtained, but also information on elusive taphonomic processes. Among the various types of bioturbation, some of them have a significant impact on the interpretation of the anatomical order system in the urn, or the degree of bone fragmentation. Others, may be misleading in the context of the interpretation of plant debris. Another group of identified bioturbators may contribute to the reconstruction of land-use and changes in the landscape.

7

The research was conducted within the National Science Centre, Poland, project no. UMO-2018/29/N/HS3/00887 entitled: Influence of (non)local population on forming crematory burial practices in the Late Bronze Age and Early Iron Age in South-Western Poland.

**THOSE BONES ARE MINE: AN ARCHAEOETHANATOLOGICAL APPROACH TO POSSIBLE DISMANTLED BURIALS FROM COLOMBA AND LES PEDROSES CAVES (ASTURIAS, SPAIN)**

**Abstract author(s):** Drak, Labib (Dpto. Biodiversidad, Ecología y Evolución, Universidad Complutense de Madrid) - Martínez-Villa, Alberto (Centro Ecomuseo de la Fauna Glacial de Onís. Asturias) - Garralda, María Dolores (Dpto. Biodiversidad, Ecología y Evolución, Universidad Complutense de Madrid) - Fano, Miguel Ángel (Dpto. de Ciencias Humanas. Universidad de La Rioja) - Arias, Pablo (IIIPC - Instituto Internacional de Investigaciones Prehistóricas de Cantabria. Universidad de Cantabria-Gobierno de Cantabria-Grupo Santander)

**Abstract format:** Oral

Archaeoethanatological approach is currently used to obtain information about funerary treatment of individuals at a given time in Prehistory or History, and also about processes by which corpses decay (Duday, 2009). The human bones recovered from the caves of Colomba and Les Pedroses (Asturias, Northern Spain) have been studied from both Anthropological and Archaeoethanatological perspectives.

A tibia and a fibula have been found in each cave, as well of some other human bones (a talus in Colomba, and a rib in Les Pedroses). In both cases they have been recovered from Mesolithic shell middens. The tibia from Colomba cave has been directly dated by 14C AMS (T0-10223: 7090 ± 60 BP; 5711-5469 cal BC; Arias et al., 2009). Les Pedroses tibia has been sampled in order to obtain a Radiocarbon date, which is currently in process.

The scarcity of human remains hinders the reconstruction of the possible funerary practices related to those sites. Yet the position of the remained bones supports the hypothesis that both finds might correspond to dismantled late Mesolithic burials. Other examples of burials in a shell midden are known in Cantabrian Spain, such as Molino de Gasparín in Asturias, El Truchiro in Cantabria and J3 in the Basque country.

8

**ARCHAEOETHANATOLOGY AND GIS: A POSSIBLE CONTRIBUTION TO A BETTER UNDERSTANDING OF THE SYNCHRONIC AND DIACHRONIC USE OF COLLECTIVE BURIALS**

**Abstract author(s):** Neves, Maria João (Universidade de Coimbra; CIAS - Research Centre of Anthropology and Health; III - Institute of Interdisciplinary Research) - Silva, Ana (University of Coimbra; CIAS - Research Centre of Anthropology and Healyh)

**Abstract format:** Oral

Although the development of Archaeotanatological approaches in Portugal began in the mid-1990, it's application to collective funerary graves remained largely to be achieved. The large amounts of bones, the lack of field anthropologists before 1999, and the perception by archaeologists that bones weren't particularly informative led to a vast accumulation of poorly contextualized and truncated osteological series.

In 1990 a prospective excavation altered this situation. Excavated by a team composed by archaeologists and anthropologists (before its legal enforcement), the hypogeum of Monte Canelas I (Portimão, Portugal) allowed a retrospective Arqueotanatological and GIS analysis of the processes that led to a vast accumulation of skeletal and archaeological materials. Later the possibility of excavating two other hypogea located in inner Alentejo region, Monte do Carrascal 2 (Ferreira do Alentejo, Portugal), turned possible the development and testing of a field protocol for the recovery of osteological remains, being all data compiled in a GIS project. The results show that these hypogea were used successively, being the corpses of non-adults and adults of both sexes laid directly on top of one another in crouched position, oriented to different cardinal directions. The radiocarbon dates, the complex stratifications, the architectural reformulations, and the amount of individuals evoke long chronologies with persistent memory of burial places for several generations from the 4th millennium until almost the beginning of the 2nd-millennium cal. B.C. Despite the good results obtained, a significant number of collective necropolis are still excavated without this kind of approach, being the financial and time consuming operations the most common criticisms for its application.

In this communication, we intend to discuss our results as well those critics, aiming to develop better ways to disseminate archaeo- thanatological and GIS approaches, indispensable to achieve an accurate interpretation of past mortuary practices.

9

**FORENSIC TAPHONOMY APPLIED TO COMMINGLED COLLECTIVE BURIALS FROM THE NEOLITHIC - CHALCOLITHIC: DIFFERENTIATING MOMENTS OF USE**

**Abstract author(s):** Moreno-Ibáñez, Miguel (Institut Català de Paleoeecologia Humana i Evolució Social - IPHES-CERCA; Universitat Rovira i Virgili, Departament d’Història i Història de l’Art) - Saladié, Palmira (Institut Català de Paleoeecologia Humana i Evolució Social - IPHES-CERCA; Universitat Rovira i Virgili, Departament d’Història i Història de l’Art; Unit associated to CSIC. Departament de Paleobiologia, Museo Nacional de Ciencias Naturales) - Morales, Juan - Cebrià, Artur - Fullola, Josep (SERP, Departament d’Història i Arqueologia, Universitat de Barcelona)

**Abstract format:** Oral

The study of human remains from a taphonomic perspective allows us to approach a holistic understanding of funerary behavior and the individuals present in the sites, especially in the case of the commingled collective burials of recent Prehistory. Through Forensic Taphonomy, we can reconstruct the taphonomic history of burial, from the last moments of the life of the individuals until our days. Consequently, it is possible to carry out a more complete study on the funerary treatment applied to the bodies in a given period, as well as to identify different moments of use of the same sepulchral space. At the Cova Foradada site (Calafell, Tarragona, Spain) we differentiated two accumulations of human remains depending on whether or not they were thermally altered. Our initial objective was to determine whether this was a single accumulation in which some of the material was burned, or whether there were two different assemblages. We studied the surface modifications of a total of 1360 unburned bone remains and 1430 burned remains using a stereomicroscope. In this way, the taphonomic modifications and the characteristics of the cremation allowed us to identify these two accumulations as the result of two different funerary practices separated in time. Firstly, the collective burial of a minimum of 18 individuals was carried out during the Late Neolithic – Chalcolithic period and subsequently, the cremation of a minimum of five individuals was carried out inside the cavity, probably towards the beginning of the Late Bronze Age. There was, therefore, a repeated use of this cavity with the same sepulchral conception for different funerary practices, inhumation and cremation, which has been possible to observe through Forensic Taphonomy.

10

**EXAMINING MORTUARY TREATMENT IN NEOLITHIC CAVES OF SOUTHWEST BRITAIN: A TAPHONOMIC APPROACH**

**Abstract author(s):** Konstantinidi, Eirini - Madgwick, Richard - Mulville, Jacqui (Cardiff University)

**Abstract format:** Oral

Current research has progressed our understanding of burial practices in caves, however, a substantial corpus of funerary remains of prehistoric date, with many dating to the Neolithic, have not been subject to holistic study. Previous research on Neolithic burials has tended to focus on biographic themes such as diet, basic information in catalogues and regional syntheses. Focus on taphonomy and mortuary practice has been very limited. These aspects represent clear gaps in Neolithic cave studies that desperately call for more research, the potential of which can only be realised with a multi-level approach.

This research employs a multi-scalar taphonomic approach to Neolithic human remains from fifteen caves in Wales and one comparative site in North Somerset. By combining macroscopic analysis of bone surface preservation and microscopic analysis of bone microstructure (histology) this research examines pre- and post-depositional treatment of the deceased and the means by which bones became disarticulated. The provision of new dating evidence from ten sites examined in Wales will also maximise the interpretative resolution of the project. Macroscopic taphonomic analysis provides information on the degree and duration of exposure of the remains, the nature of manipulation and/or disturbance and modifying agents that impact the bone. Microscopic analysis (thin section transmitted light microscopy) provides insight into early post-mortem processes and reveals the rate and nature of soft tissue decay by assessing the degree and nature of microstructural bioerosion. This presentation outlines findings from the taphonomic analysis on sites across Wales. Burial patterns and practices revealed from analysis of disarticulated remains will be presented, including some unusual case studies, and future plans for analysis described.

11

**THE CROSS-DISCIPLINARY PARADIGM LAG: ARCHAEOETHANATOLOGICAL ANALYSES AND SOCIOCULTURAL ANTHROPOLOGICAL MODELS IN THE ARCHAEOLOGY OF BRONZE AGE CRETE**

**Abstract author(s):** Finn, Ellen (British School at Athens)

**Abstract format:** Oral

Archaeoethanatological and taphonomic analyses are asking new questions of prominent interpretative frameworks. However, although these approaches are now critical to the archaeology of death, their findings must often contend with entrenched frameworks of interpretation born from sociocultural anthropology. One area in which this is most apparent is in interpretations of engagement with bodily decomposition, a process framed by the conflated models of Robert Hertz (1906), Arnold Van Gennep (1906) and Victor Turner (1967, 1995) as a source of fear, revulsion and pollution.

This paper will discuss the consequences of cross-disciplinarity in the interpretation of the human remains of Prepalatial Crete (c. 3200-1900 B.C.), namely the paradigm lag between recent archaeoethanatological evidence and the extensive application of the anthropological models of Van Gennep, Hertz and Turner. With reference to the recent evidence from the east Cretan sites of Petras and Sissi, it is argued that while these anthropological models have acted as the basis for many influential case studies of funerary practices, conflicting archaeoethanatological data illustrates the urgent need for their clear definition and critical reconsideration.

12 This paper thus highlights that while archaeothantological and taphonomic approaches have much to contribute to our understanding of the past, any attempt at fostering cross-disciplinary approaches must begin with the acknowledgement of such an endeavour’s reliance on clear definition, terminology and theoretical consistency.

12 ONE IS NOT ENOUGH, IT’S TOMB 21: TAPHONOMY AND CHANGE IN THE EARLY MYCENAEAN AYIOS VASILEIOS NORTH CEMETERY, GREECE

**Abstract author(s):** Moutafi, Ioanna (The Malcolm H. Wiener Laboratory for Archaeological Science, American School of Classical Studies at Athens; Center for Hellenic Studies, Harvard University) - Voutsaki, Sofia (University of Groningen)

**Abstract format:** Oral

Social Bioarchaeology and mortuary studies in general have received a new impetus through the emerging fields of funerary taphonomy and archaeothanatology. Multi-dimensional taphonomic analyses enable the reconstruction of funerary acts with unprecedented accuracy, and add depth and nuance to our interpretations. Taphonomic approaches are especially useful for the study of multi-staged burial rites that result in “difficult” funerary assemblages, characterised by multiple interments and commingled remains.

Burial customs in the southern Greek mainland in the Late Bronze Age (or Mycenaean period, ca. 1700-1100 BC) are a characteristic example of this category, showing increased complexity and new funerary practices (new and larger grave types, multiple burials, ‘secondary treatment’, etc). The recent excavation at Ayios Vasileios in Laconia brought to light an Early Mycenaean cemetery (North Cemetery, ca. 1700-1500 BC), in use exactly during the period when these new practices are being introduced. This cemetery therefore offers a unique opportunity to explore changes of mortuary practices by means of an integrated bioarchaeological approach which pays equal attention to biological and cultural evidence (taphonomy, architecture, human remains, artefacts). Our paper focusses on the long history of an exceptionally large tomb (Built Tomb 21) with an unusually large number of burials (MNI:>30) in variable internal contexts (primary and secondary assemblages placed in different levels, pits and bone piles). Using a multi-disciplinary set of taphonomic methods, our main aim is to reconstruct the details of funerary actions and establish the sequence of use. Our ultimate aim, however, is to go deeper: we would like to study the process of change itself, i.e. understand the process of innovation and experimentation which led to the crystallisation of new mortuary practices in the North Cemetery and the southern mainland in general.

13 IRON AGE MORTUARY PRACTICE IN SOUTHWEST BRITAIN

**Abstract author(s):** Bricking, Adelle - Madgwick, Richard - Sharples, Niall (Cardiff University)

**Abstract format:** Oral

This research aims to shed light on the enigmatic Iron Age (800 BC-AD 43) mortuary practices in southwest Britain using a multi-scalar suite of secondary data collection and primary macroscopic and microscopic analyses. The first part of the research explores the various means of corpse disposal by compiling all available human remains data into a coherent database allowing statistical comparison of burial characteristics (site, feature, context, deposit, and associations). However, the dead were subject to various treatments prior to disposal, as indicated by different states of skeletal completion and fracturing in Iron Age sites. Data from secondary analysis alone limits insight into aspects of a complex funerary rite, thus the need for a holistic study incorporating examination of surface taphonomy and microscopic analysis is evident.

Thin section light microscopy of bone diagenesis can be used to identify processes that a body went through prior to disposal (such as burning and rates of exposure to the elements) and, in some cases, what environment decomposition occurred. This PhD research compares diagenetic change from c.200 human bone samples from 17 sites across the region ranging in articulation (from whole inhumations to scattered limbs and fragments) recovered from a variety of environments and features (e.g. ditches, middens, pits, postholes, graves, caves, and cists). This paper presents the results of the analyses and attempts to reconstruct patterns of deposition and early post-mortem treatment in Iron Age Britain.

14 HALTING DEATH IN ITS TRACKS: HISTO-TAPHONOMIC METHODS FOR INVESTIGATING CURATION AND ACTIVE MANIPULATION OF CORPSES IN IRON AGE BRITAIN

**Abstract author(s):** Tollefsen, Emma (University of Manchester)

**Abstract format:** Oral

Recent advances in histo-taphonomic studies have dramatically changed our understanding of the complexities of mortuary treatments during both the Neolithic and Bronze Age periods in Britain. But what about the Iron Age: An era renowned for its naturally curated ‘bog bodies’ and ‘kept’ human remains, sometimes modified into objects?

This paper presents the results of the first cross-regional study of this phenomenon, probing the famously diverse burial practices of Wessex and the inhumation tradition of East Yorkshire. It reveals diverse and intriguing burial assemblages from iconic sites such as Danebury Hillfort and its Environs, reflecting on what this might tell us about mortuary ideology. The ‘Arras Culture’ rites of East Yorkshire is re-evaluated, showing equally complex trajectories of the dead towards final interment. This study demonstrates the merits of using diagenetic data alongside archaeothanatological frameworks to piece together post-mortem treatments of the dead.

This research introduces two new conceptual terms: ‘delayed decomposition’ – indicative of partial cessation of decay – and ‘deferred decomposition’ – reflecting more active anthropogenic intervention to curate a corpse. This paper suggests that these strategies were actively employed to facilitate more complex temporalities of burial and deposition, not just to create ancestral bodies which might linger longer amongst the living or curate enemy relics, but as a response to particular kinds of death and perceived agencies of the deceased. These findings build on new and fascinating research into elusive burial rites in Iron Age Britain (e.g. Booth and Madgwick 2016; Tollefsen 2016).

This paper proposes a contrastive range of practices through which differential curation might be achieved and will resituate them within the wider context of communities actively experimenting with long-term storage in many other ways: bringing both a practical and ideological notion of intervention in time and decay, to transform mortuary practices in this millennium.

15 SAME SAME BUT DIFFERENT – DISARTICULATED IRON AGE HUMAN REMAINS FROM BASEL-GASFABRIK (SWITZERLAND)

**Abstract author(s):** Pichler, Sandra L. - Stopp, Barbara - Brönnimann, David (IPAS University of Basel) - Spichtig, Norbert (Archäologische Bodenforschung Basel-Stadt)

**Abstract format:** Oral

Disarticulated human remains are a regular occurrence in Iron Age sites, especially during the La Tène period. They are usually recovered from inside settlements, both in apparent ritual installations and common features like settlement pits or layers in residential areas or craft zones. These disarticulated bones are interpreted as relics of multi-stage funerary practices including exposure and excarnation and often display traces of perimortem and post-mortem modifications. At the La Tène period Basel-Gasfabrik site, all human skeletal remains were systematically extracted from the hand-collected animal bones in a screening process. The complete sample was then analyzed using largely the same parameters employed in animal bone studies, albeit with special regard to forensic and post-mortem taphonomic indicators. The study found that, even though all skeletal elements are represented among the human remains, bone frequencies do not correspond to their anatomical proportions. While all age groups and both sexes are present, the proportion of young male individuals stands out the sample’s demographic profile. There are also conspicuous differences regarding the frequency and type of intra-vitam and perimortem trauma as well as animal gnawing. A comparative evaluation of post-mortem taphonomic indicators on human and animal bones from the same archaeological features revealed both similarities and discrepancies, yielding insights into the differential treatment of dead bodies. Such differences also emerged in a histotaphonomic analysis of a sub-sample of long bones.

16 BONE FIRE SIGNATURES ON CREMATION BURIALS FROM ROMAN LUSITANIA PROVINCE

**Abstract author(s):** Silva, Filipa (Research Centre for Anthropology and Health - CIAS, University of Coimbra)

**Abstract format:** Oral

The understanding of the cremation practice on past populations, particularly the burning process, is based on bone fire signatures such as color change, deformation and distinct thermal fractures. Through the macroscopic study of cremated human bone from 117 burials (1st-2nd centuries AD) associated to two Roman cities in Lusitania province, namely Augusta Emerita (Mérida, Spain) and Salacia (Alcácer do Sal, Portugal) this work aims to analyze the bone fire signatures observed on these sites according to the biologic profile of individuals and the burials’ characteristics.

The main color per burial indicates the burning process was more efficient among individuals from Salacia, especially adults. Furthermore, no significant differences were noted between males and females from both sites. Regarding the percentages of bone deformation and thermal fractures they are also higher on the Salacia sample, and more common among female individuals. The high values of curved transverse fractures and deformation found on both samples point out to a potential scenario of individuals’ cremation shortly after their death (cadaver phase). Nonetheless, the interpretation of burning signatures on cremated bone from archaeological contexts is quite challenging because their manifestation is multifactorial. It depends on extrinsic and intrinsic variables, whose influence could not be fully acknowledged.

17 MICROTAPHONOMIC APPROACH TO ARCHAEO THANATOLOGY: A CROSS-DISCIPLINARY PERSPECTIVE FROM A VISIGOTHIC FUNERARY CAVE CONTEXT (LA GARMA, CANTABRIAN SPAIN)

**Abstract author(s):** Camarós, Edgard (McDonald Institute for Archaeological Research. University of Cambridge) - López-Gijón, Ramon (Universidad de Granada) - Zurro, Débora (Institució Milà i Fontanals - IMF-CSIC) - Gutiérrez-Zugasti, Igor (Instituto Internacional de Investigaciones Prehistóricas de Cantabria - IIIPC. Universidad de Cantabria) - Sánchez-Moral, Sergio - Martín-Pozas, Tamara (Museo Nacional de Ciencias Naturales - MNCN-CSIC) - Sánchez Carro, Miguel Ángel (Instituto Internacional de Investigaciones Prehistóricas de Cantabria - IIIPC. Universidad de Cantabria) - Gleba, Margarita (Ludwig-Maximilians-University of Munich) - Ontañón, Roberto (Instituto Internacional de Investigaciones Prehistóricas de Cantabria - IIIPC. Universidad de Cantabria; Museo de Prehistoria y Arqueología de Cantabria - MUPAC) - Arias, Pablo (Instituto Internacional de Investigaciones Prehistóricas de Cantabria - IIIPC. Universidad de Cantabria)

**Abstract format:** Oral

The present contribution seeks to untangle the funerary practices developed in the Lower Gallery of La Garma (Cantabrian Spain) during the early medieval period. At different zones of the Lower Gallery (i.e., Zones IV and V), an intact Visigothic deposit including

five skeletons dating to the seventh-eighth centuries AD were discovered. An archaeothanatological approach to two of the five Funerary locus has been combined with the analysis of microsamples from these contexts. We define microsamples as the minimum amount of necessary sample in terms of conservation strategies of this site declared World Heritage by UNESCO. A cross-disciplinary microtaphonomic perspective (e.g., paleobotany: fibers, phytoliths and microorganisms: parasites) has been implemented to analyze the archaeological funerary context, in addition to the use of non-destructive techniques (i.e., photogrammetry and bone surface casting) and integrated in a general taphonomic study.

The results of our research are presented in order to a better understanding of early medieval beliefs and attitudes towards death through an extraordinary snapshot of the Visigothic period, but also with the aim of advancing in the methodological analysis of funerary contexts and human remains from a taphonomic perspective.

18 TAPHONOMY AND ‘ANCIENT’ HUMAN REMAINS IN THE MEDIEVAL MIND

**Abstract author(s):** Nugent, Ruth (University of Liverpool)

**Abstract format:** Oral

While modern archaeothanatology has been advanced by archaeologists in increasingly refined ways in the 21st century, there is perhaps a need to also reflect on the potential long history of taphonomic and pseudo-taphonomic methods which pre-date the (post-)modern period.

The exhumation of the ‘ancient’ dead in medieval Britain (England, Scotland, Wales) and the methods, meanings, and perceptions inherent in this activity, has never before received dedicated study. However, a new UKRI Future Leader’s Fellowship launched in November 2019 is addressing this issue using textual and archaeological evidence from across the period, and analysing this large dataset using complex interrogative tools and methods from Digital Humanities (Corpus Linguistics, Natural Language Processing, Machine Learning).

Using detailed, explicit accounts of investigations into ‘ancient’ burials, written during the medieval period (5th-15th century) in Britain, this paper will explore how the aims and principles of archaeothanatology might be identified in a pre-forensic, ‘pre-archaeology’ society and explores what role taphonomy played in early ‘scientific’ and proto-archaeological interpretations of ‘ancient’ human remains. This is not to argue for direct continuity of approaches and ideas, but to investigate how the remains of archaeological bodies were understood taphonomically, and how taphonomy contributed to their interpretations of the long-dead in medieval Britain, taking our understanding of burial disturbances beyond merely ‘veneration or violation’ of the dead and instead trace how the knowledge, experiences, methods, beliefs and ethics of the medieval period influenced and shaped people’s desire to ‘read’ and ‘reverse engineer’ archaeological human remains, how effective this was in a pre-forensic society, and to what purpose. This in turn may help us as modern archaeologists reflect on the aims, caveats, and influences surrounding our own use and discussion of archaeothanatology in both quantitative and qualitative research today.

A. MAXIMISING SKELETAL DATA COLLECTION IN COMMERCIAL ARCHAEOLOGY

**Abstract author(s):** Chroustovsky, Lubos (Faculty of Arts, University of West Bohemia in Pilsen) - Pruchova, Erika (Faculty of Arts, University of South Bohemia in Ceske Budejovice) - Kacel, Pavel (Archeo Pro o.p.s. Prague)

**Abstract format:** Poster

This paper explores the application of quick, simple and low-cost procedures for data collection in commercial-driven salvage or rescue archaeology and evaluates methodologies to manage complex cemetery excavations from a bio-anthropological perspective. Commercial archaeological excavations operate under numerous constraints, such as limited funding, tight deadlines, demanding developers, and varying degrees of public engagement. In order to be successful, they require unique approaches to data collection that differ significantly from more stable long-term academic projects. This requires the application of tailored field techniques and interdisciplinary collaboration between archaeologists, anthropologists and developers in order to maximise results. The authors examine procedures recently utilised to document and preserve skeletal data in three post-mediaeval cemeteries in Prague, and evaluate their efficacy. The basic methodical steps presented can be easily modified for specific site requirements and combined with more complex (or costly) methods when these are available. Therefore, the findings from this study are applicable to numerous archaeological contexts beyond commercial salvage archaeology.

B. PRELIMINARY TAPHONOMIC EVALUATION OF A BRONZE AGE HUMAN SKELETON DISCOVERED AT RUGINOASA (IASI COUNTY, ROMANIA)

**Abstract author(s):** Petraru, Ozana-Maria - Bejenaru, Luminița (“Alexandru Ioan Cuza” University of Iași, Faculty of Biology; Romanian Academy – Iași Branch, “Olga Necrasov” Center of Anthropological Research) - Simalcsik, Angela (Romanian Academy – Iași Branch, “Olga Necrasov” Center of Anthropological Research) - Tencariu, Felix-Adrian (“Alexandru Ioan Cuza” University of Iași, Interdisciplinary Research Institute, Science Department, Arheoinvest Centre)

**Abstract format:** Poster

Archaeological excavations carried out in 2020, at Ruginoasa (Iași County, Romania), revealed a Bronze Age human skeleton in a burial context. The skeleton was oriented West-East, in a crouched position on the right side, facing South. The tomb was discovered in an alveolar pit, which penetrate in the level of a Chalcolithic Cucuteni settlement. Although the taphonomic process has been

intensely studied on the human bones, the teeth have not been studied with the same intensity. Furthermore, the morphological differences between trauma and taphonomic changes represents occasionally a challenge due to the limits of interpretation. The aim of this study is to assess the taphonomic changes of the human skeletal remains (i.e., bones and teeth) discovered in the above-mentioned archaeological site. The estimations of age at death and sex, along with macroscopic and microscopic analysis were applied. The skeleton belonged to a male with an age at death of 45-50 years. A fracture was identified in the left clavicle, antemortem produced and healed, resulting a deviation from normal bone axis. Several postmortem fractures were identified in ribs, vertebrae, and in the bones of the feet and hands. Subaerial weathering exfoliation was identified on the diaphysis of humeri and tibias, along with traces left postmortem by rodent teeth on the crests of tibias. On the teeth, white sinuous lines of opacity were observed in enamel and dentine, probably produced by hypomineralization. Also “tunnel” like external alterations were observed on the enamel and dental root surfaces. We presume that the lines of hypomineralization existed antemortem, but ones of them were altered postmortem by environmental factors. Considering the limitations of the light microscopy in distinguishing taphonomic and enamel hypomineralization features on archaeological teeth, further research is necessary regarding the alterations of the dental tissues.

C. THANADOS - THE ANTHROPOLOGICAL AND ARCHAEOLOGICAL DATABASE OF SEPULTURES

**Abstract author(s):** Brundke, Nina (Austrian Archaeological Institute) - Eichert, Stefan (Natural History Museum Vienna)

**Abstract format:** Poster

For the area of present day Austria burials are the main archaeological source for the Early Middle Ages ( ~ 600 - 1100 CE ) as in comparison there are hardly any settlements excavated. While only a handful of early medieval settlements are known there are several hundred cemeteries with thousands of graves that are published mostly in a very traditional way in form of printed books with catalogs, maps, figures and plates. Regarding thanatoarchaeological questions they serve as the main source. Although nowadays many publications are open access, the underlying data (i.e. catalogs etc.) are not available as structured digital data that can be used further for digital analyses. Neither is it possible to get a glance at the big picture as mostly only single sites are processed. Cross site publications or homogenous data ranging over more than one site are hardly available.

Within the THANADOS Project (<https://thanados.net>) we developed open source web applications to collect data on burials and their context and to disseminate, query, analyse and visualise the data respecting the FAIR principles based on the CIDOC CRM standard of the International Council of Museums. The area of present day Austria served as a case study and the data pool consists of appr. 500 burial sites with altogether roughly 5000 graves and several thousand finds that are provided as open data under open licences.

The proposed poster wants to present this project and show how it can serve as a hub for cross disciplinary thanatoarchaeological data.

392 IDENTITY POLITICS AND CULTURE(S) IN NEOLITHIC AND BRONZE AGE ARCHAEOLOGY

**Theme:** 6. Material culture studies and societies

**Organisers:** Arponen, VPJ (Kiel University) - Brinkmann, Johanna (Kiel University) - Johannsen, Niels (Aarhus University)

**Format:** Regular session

Identity politics has taken a central place in contemporary political and cultural discourse. On the one hand, the concept can denote a political strategy that uses identity, increasingly weaponising it politically to suggest societal polarisation and social divides. On the other hand, some argue identity politics is a symptom of real socio-economic transformations taking place in modern society.

In Neolithic and Bronze Age archaeology we witness a wide range of material phenomena which frequently have been associated with identities on smaller and larger scales, such as the occurrence of megaliths and the emergence and spread of copper and bronze artefacts as well as phenomena like corded ware or bell beakers, just to name a few.

This session invites contributions to discuss identity politics from an archaeological perspective by means of specific case studies as well as theoretical contributions. Do we have examples of politicised identity in Neolithic and Bronze Age Europe? What kind of social and cultural transformation trajectories do we witness in these cases? Which are the essential triggers and causes of transformation that can be identified in these case studies? What can we learn from prehistory with regard to modern day identity politics, and vice versa?

We also wish to see reflective, theoretical contributions looking at, for example, the relation and/or discrepancy between archaeological concepts of culture and identity. To what extent do these concepts in archaeology reflect the complexity of factors shaping contemporary identity politics? Conversely, do modern (Western) constellations provide a suitable frame of reference for studying these phenomena in prehistory? Can archaeological concepts of identity and culture be weaponised politically today?

- 1

### IDENTITY POLITICS IN AN INTERDISCIPLINARY CONTEXT: A CONCEPTUAL ANALYSIS

**Abstract author(s):** Arponen, VRJ (Institut fuer Ur- und Fruehgeschichte Kiel)

**Abstract format:** Oral

In this talk, the concept of identity politics is approached from an interdisciplinary philosophical and reflective perspective as a theoretical construct calling for an analysis of the concept’s ontological commitments. Intuitively, identity might be thought of as essentially a cognitive process of categorisation, acknowledgment, and belonging. Archaeological work on material culture, architecture, and social memory implies a cognitive concept of identity (even while, per Hawke’s ladder, strictly beyond the reach of archaeological data). From the cognitive concept of identity follows a concept of identity politics as manipulation of those cognitive processes for political ends.

However, the cognitive concept of identity displays certain romantic and conservative aspects. It is romantic, for it casts an emotional “sense of belonging” as central to identity, especially to cultural or social identity —which in archaeological contexts might even be seen as harking back to colonialist concepts of the “primitives” as uncritically cognitively attuned to their prevailing “symbolic orders”. It is conservative, because it implies that a sustainable cultural and social identity can only be a “herd mentality” of a homogeneous, alike thinking and feeling, cognitive community.

Here, the concepts of emergence and capability might offer a plausible extension of the cognitive concept. An emergent identity is a dynamic, “issue specific” identity that is generated and emerges at moments of “reading” or “encoding” of particular socio-cultural, political, economic, and environmental contexts and that may recede and be reshaped again in other contexts. Capabilities denote potential opportunities and perspectives available to members of socio-cultural, political, economic and environmental communities in those contexts. Following David Graeber’s action-based theory of value, identity can be conceived as orientated towards capability-enhancing community building in which, not the emotional and static belonging to the community as such, but the leading of active lives as a recognised member of the community is central.

### CAUSEWAYED ENCLOSURES AND LONG BARROWS AS LANDMARKS OF THE NEOLITHIC RITUAL LADNSCAPE IN BOHEMIA

**Abstract author(s):** Turek, Jan (Center for Theoretical Study, Charles University, Prague) - Kristuf, Petr (Department of Archaeology, Uiversity of West Bohemia in Pilsen)

**Abstract format:** Oral

Main focus of our project is reconstruction concept of ritual landscapesand representatuion of personal and communal identity during the Neolithic Period and Copper Age in Bohemia. Specifically we focus on the possibilities of reconstruction of the ritual landscape and settlement areas in relation to funerary monuments and ancestral monuments, such as causewayed enclosures. The death as a social event was never isolated from social, economic and symbolic life of farming communities. The ceremonial level of funerary events connected to ancestral worship is reflected in the landscape with variety of monuments and their intra and extra territorial relations. The ritual landscape was constructed in long tradition symbolic system. The cultural landscape of prehistoric farmers was divided and structured in a continuous diachronic development and the archetypes of landscape divisions and monuments (enclosures; hill-top sites; long barrows) as landmarks was part of the cosmological legacy for generations.

We attempt to explore the palimpsest of funerary and ceremonial land use in order to reconstruct the long term perception of the farmer’s world and its structure. In this approach some monuments, seemingly isolated, fit into much wider spatiotemporal structure of prehistoric community areas. Spatial studies of 5th - 3rd Millennium BC will be presented from the territory around the Vltava and Elbe confluence and the mythical mount of Říp.

### FRAMING PAST IDENTITIES

**Abstract author(s):** Mlekuž Vrhovnik, Dimitrij (University of Ljubljana; Institute for the protection of the cultural heritage of Slovenia)

**Abstract format:** Oral

Contemporary identity politics refers to political stances rooted in experiences of injustice shared by excluded social groups. It is marked by multiplication of overlapping identities and their use in fighting various forms of oppression. This seems to be a relatively novel phenomenon. How to frame past identities?

I will approach past identities using the Lacanian psychoanalysis.

Identities can be framed within two registers. The first is the “imaginary axis”; this is the domain of inter-subjectivity that functions to support and consolidate the images subjects use to substantiate themselves. This is the register of identity politics and it is usually invoked when we approach past identities (individual identity, visible through personal adornment and ornaments). This kind of identity is most fluid and prone to change.

The second register of identity occurs along the “symbolic axis”. This axis provides the subject with a symbolic framework, and it ties them into a variety of roles and social contracts. Importantly, it entails the radical alterity of what Lacan refers to as ‘the big Other’;

### A WARRIOR IDEOLOGY IN LATE NEOLITHIC CENTRAL EUROPE?

**Abstract author(s):** Schultrich, Sebastian (Institut fuer Ur- und Fruehgeschichte Kiel)

**Abstract format:** Oral

In northern Central Europe, a male warrior ideology often is associated with the Final Neolithic concepts of Corded Ware and Bell Beakers. This ideology is particularly reflected in burials, where individuals were buried according to specific and gender related rules and males exclusively were accompanied by artefacts with warlike connotations. This burial custom and the ideological, binary social roles associated with it are seen as an opposition to the egalitarian burials of the Late Neolithic (3300–28/2700 BC) societies.

In Southern and Eastern Europe, however, corresponding burials can be traced back to the fourth millennium. On closer examination, many of the attributes that contribute to the assumption of warrior ideology there can also be observed in Central Europe at the same time. In particular, shaft-hole battle axes are to be understood as an outstanding symbol. They represent a symbol that became a common burial gift at the end of the fourth millennium. Before that, they were mainly isolated finds. Moreover, battle axes were articulated in copper, stone as well as in pictorial art and thus they were associated with ideology in a particular way. They reflect the symbolic value that daggers and halberds had in southern Europe.

Although it will never be possible to reconstruct to the actual ideology, it is clear that Central Europe was an active participant in these novel ideas already in the fourth millennium BC. Thus, the assumed distinction between Late and Final Neolithic societies must be abolished. The historical significance of the Beaker cultures must be put into perspective.

However, it should be noted that the general concept of a warrior ideology must be viewed critically, and the implicit assumption of a gender distinction is to be doubted. Supposedly warlike attributes cannot be clearly equated with a masculine symbolic world.
- 5

### POTS AND PEOPLE? THE IMPLICATIONS OF THE CONCEPTS OF ARCHAEOLOGICAL CULTURE AND POLITICISED IDENTITY IN THE NORTHERN EUROPEAN NEOLITHIC

**Abstract author(s):** Brinkmann, Johanna (Institut fuer Ur- und Fruehgeschichte Kiel)

**Abstract format:** Oral

At least since Childe (1925, 1929) classic definition of archaeological culture as a complex of recurring types of remains (pots, implements, burial sites, houses) that form the material expression of a (homogenous) group of people, the concept of culture has been used in archaeology to divide material culture into entities which are fixed in time and space. Alternatively single artefact types or features such as particular forms of megalith tombs are used as “type fossils” which in many cases are also viewed as social entities („passage tomb people”). Several scholars have remarked that such uniformity is hardly ever questioned, because the idea of a corresponding social group, has already been imposed itself on the classification process (see e.g. Furholt 2014). Arguably, this form of implicitly imposed circular reasoning, where the result is taken as a premise, causes an emphasis on division of material culture rather than on continuity and fusion. The uncritical use of the concept of archaeological culture therefore cements the division of the past into homogeneous social groups. In a similar way the concept of identity has been used to describe fixed social entities, sometimes implying a “clash” of identities i.e. of different groups of people. In this way both concepts often neglect the variability in the archaeological material. Despite of the increasing use of absolute dating methods, a detachment of the chronology from the archaeologically defined cultures/entities does often not take place. It is shown, that such a detachment is very beneficial and allows for the structured comparison of the material culture in a particular area, in this case the British Isles, Scandinavia and Northern Germany, without an overemphasis on cultural division.

### WHO WERE THE FIRST POTTERS? CURRENT RESEARCH IN EARLY POTTERY PRODUCTION IN WESTERN EURASIA. PART 1

**Theme:** 6. Material culture studies and societies

**Organisers:** Spataro, Michela (The British Museum) - Dolbunova, Ekaterina (The State Hermitage Museum) - Mylnikova, Liudmila (Siberian Branch Institute of Archaeology and Ethnography of the Russian Academy of Sciences)

**Format:** Regular session

Pottery appeared throughout this huge territory, between Western Siberia, the Mediterranean and the Atlantic Ocean, between c. 8000 and 4000 cal BC, following different trajectories, cultural choices and needs.

We are interested in how the first pottery was made throughout western Eurasia, and particularly in links between technological, morphological and decorative traditions in different regions. We welcome contributions based on interdisciplinary research, using archaeological evidence, ethnoarchaeology and archaeological science, and addressing questions including:
- 597

- Was the first pottery always technologically unelaborated?
- Was the chaîne opératoire of the first pottery determined by environmental constraints, economic and demographic factors, or the historical trajectory of the spread of pottery?
- Were early pottery forms based on existing container shapes or new functional requirements?
- How significant is decoration in explaining the spread of the earliest pottery in Eurasia?
- How were different aspects of ceramic production (technology, morphology and decoration) changed or maintained while pottery was dispersed?

ABSTRACTS:

1 EMERGENCE OF POTTERY IN THE NENJIANG RIVER BASIN (NORTHEAST CHINA) DURING THE EARLY NEOLITHIC: UNDERSTANDING TECHNIQUE THROUGH THIN-SECTION ANALYSIS

**Abstract author(s):** Duval, Pauline (Ecole Pratique des Hautes Etudes - EPHE; Jilin University, School of Archaeology) - Keute, Jennifer (Oxford University, School of Archaeology) - Sebillaud, Pauline (CNRS-CRCAO UMR8155; Heilongjiang University) - Wang, Lixin (Jilin University, School of Archaeology)

**Abstract format:** Oral

Since the early 2000's archaeological excavations in the Nenjiang river basin have led to the discovery of some of the oldest pottery assemblages in Northeast China, notably at the sites of Houtaomuga and Shuangta (13.000 – 7.500 cal BP). These ceramics are important as they present the emergence of ceramic technology in the region. It has been hypothesized that this is the result of a dietary shift which relies more on fishing.

This research provides a comparative analysis of pottery from the two sites in question using thin-section petrography. The aim of this work is to characterize practices of pottery production for each phase by considering technological and morpho-stylistic evidence in order to highlight cultural transmission. Preliminary results show Houtaomuga phase I (13.000 – 11.000 cal BP) pottery is plant-fiber tempered, while Shuangta phase I (11.000 – 7.500 cal BP) and Houtaomuga phase II (8.000-7.500 cal BP) sherds are shell tempered. The selection and the processing of raw materials seem to significantly vary with the form and decoration of ceramics. The long-term cultural sequence of these sites offer insight into transmission of ceramic technology during the early Neolithic in a hunter-gathering society.

2 EMERGENCE OF POTTERY IN THE NENJIANG RIVER BASIN (NORTHEAST CHINA) DURING THE EARLY NEOLITHIC: UNDERSTANDING THEIR USE THROUGH RESIDUES

**Abstract author(s):** Keute, Jennifer (School of Archaeology, University of Oxford; Research Laboratory for Archaeology and the History of Art) - Duval, Pauline (Ecole Pratique des Hautes Etudes - EPHE; Jilin University, School of Archaeology) - Sebillaud, Pauline (CNRS-CRCAO UMR8155; Heilongjiang University) - Wang, Lixin (Jilin University, School of Archaeology) - Deviése, Thibaut (School of Archaeology, University of Oxford; Research Laboratory for Archaeology and the History of Art) - Hein, Anke (School of Archaeology, University of Oxford)

**Abstract format:** Oral

Since the early 2000's, archaeological excavations in the Nenjiang river basin have led to the discovery of some of the oldest pottery assemblages in Northeast China, notably at the sites of Houtaomuga and Shuangta (13.000 – 7.500 cal BP). These ceramics are important as they present the emergence of ceramic technology in the region. It has been hypothesized that this is the result of a dietary shift which relies more on fishing.

One way to approach this hypothesis and the issue of the relationship between pottery use and changes in subsistence and food preparation methods is through the analysis of organic residues trapped in these sherds. The research presented here examines absorbed lipid residues from 200 total pottery sherds from the Houtaomuga and Shuangta sites to shed light on pottery use among hunter-gatherers in this region. These samples come from Houtaomuga phase 1 through 4 and Shuangta Phase 1 and 2, in an attempt to understand pottery use over an extended period of site occupation. Residues have been extracted from the sherds using a method that does not require the sherds to be damaged and allows for more organics to be recovered. Extracts obtained have been subsequently characterized and quantified using gas chromatography-mass spectrometry (GC-MS). This paper will discuss the results of these analyses, focusing in particular on what they can tell us about changes in subsistence and food preparation practices over time.

3 EARLIEST POTS: SHAPES VARIABILITY (EAST ASIA AS A CASE STUDY)

**Abstract author(s):** Zhushchikhovskaya, irina (Institute of History, Archaeology & Ethnography of Peoples of Far East FEBRAS)

**Abstract format:** Oral

The research area discussed in this paper includes the Japanese archipelago, southern and northeast China, southern Russian Far East. The first pottery appeared in these regions between 20,000/18,000 and 10,000 BP. Ceramics assemblages are not numerous containing mainly small-sized fragments. The database for pottery shapes examined is very restricted allowing preliminary estimated observations.

Earliest ceramic containers of all regions are characterized by basic morphological complexity. There is no structural distinction between main pot's functional parts – body and orifice. Morphological diversity is caused mostly by the modeling of pot's bottom part. Three kinds of bottom part contour can be distinguished – conical-shaped, roundish-shaped and flat line-shaped. Flat bottoms are characteristic for the earliest pots of Russian Far East and areas of northeast China. Conical-shaped and roundish-shaped bottoms occur in southern China area and partially in northern China. Among the earliest pottery of the Japanese islands all kinds of shapes bottoms are presented. So, the oldest ceramics assemblages of East Asia show almost synchronic appearance of different bottom models – conical/roundish one and flat horizontal one.

The earliest shapes of ceramic containers are quite similar to the shapes of traditional containers made of various organic materials (plants, fibers, leather). Many kinds of these containers having very old technological routes are survived in East Asia until present. Hypothetically, the process of imitation of shapes of organic containers by the shapes of the earliest clay containers might have various social and technological patterns.

4

EARLY POTTERY IN WESTERN SIBERIA: CHRONOLOGICAL AND TYPOLOGICAL ASPECTS

**Abstract author(s):** Dubovtseva, Ekaterina (Institute of History and Archeology of the Ural Branch of the Russian Academy of Sciences - IIAA UB RAS) - Piezonka, Henny (Institute of Pre- and Protohistorical Archaeology, Christian Albrecht University Kiel) - Klementieva, Tatyana (Institute of History and Archeology of the Ural Branch of the Russian Academy of Sciences - IIAA UB RAS)

**Abstract format:** Oral

Western Siberia is a key region for understanding early hunter-gatherer pottery dispersals in North Eurasia. Located halfway between the earliest Late Glacial cores of pottery production in East Asia, and Eastern Europe, Western Siberia plays a prominent role in various dispersal scenarios currently under discussion. In the study region, the early pottery horizon coincides with a unique set of innovations and intensification in the socio-economic sphere. Recently published results of a thorough AMS dating programme show that the earliest reliable evidence for pottery stems from the south and west of the area, dating to the second half of the 7th millennium cal BC. Over the following centuries, the innovation spread rapidly north into the taiga.

The talk will present new typological, contextual and chronological data from across the region. At least two major styles dominate the earliest ceramics in the taiga zone in the 7th millennium cal BC: flat-based vessels with incised ornamentation, and pointed-based vessels with comb stamp decoration. The first type is dominating on sites in the middle and southern taiga and in the forest steppe to the south, whereas the second type is concentrated in the northern taiga north of the West Siberian land ridge and in the Lower Ob' region. However, at some sites both styles are present in the same contexts, as is the case e.g. at the fortified settlement of Amnya I. In the first half of the 6th millennium calBC, the stylistic diversity, especially concerning decoration, is further increasing.

In our talk, we will compare selected early pottery complexes, including new materials from the Middle and Lower Ob' regions, and from the Konda area. We will also provide insights on dispersal trajectories, roles and functions of these early wares within the dynamic socio-economic system of the hunter-gatherer-fisher communities.

5

TECHNOLOGICAL CHARACTERISTICS OF THE EARLY NEOLITHIC CERAMICS IN VOLGA-KAMA

**Abstract author(s):** Vybornov, Alexander - Vasilieva, Irina (Samara State University of Social Sciences and Education)

**Abstract format:** Oral

One of the most relevant issues in studying the Neolithic in Volga-Kama is to determine the particular qualities of emergence and spread of the ceramics traditions at this territory. This is due to the very early age of the Neolithic complexes: 6500 BC. This presupposes the existence of centres where the ancient crockery emerged. Our study of the pottery technology attaches particular importance to the ideas about the initial plastic raw material and the traditions of composing molding materials. They remain unchanged for a long time even when different population groups intermingling. The difference in the types of plastic raw materials of the earliest ceramics points to belonging of the ancient pottery to different areas of ceramics origin. The technical and technological analysis of the pottery revealed three areas of the emergence and development of ceramic traditions in the Volga-Kama: the north of the Caspian Sea, the Middle Volga and the Kama. The main mechanism of spread of the early Neolithic ceramic traditions was direct contacts and intermingling processes of culturally different groups of the ancient population. As a result of intermingling of early Neolithic traditions from the north of the Caspian Sea and the Middle Volga (Elshanskaya culture), a syncretic Middle Volga culture formed with a specific technology of making pottery. In conditions of intercultural intermingling outwardly similar vessels could be made by different technological methods. Thus, the ceramics with comb stamp decoration and made of natural clay, that was dry crushed and chamotte admixed, was predominant at the early stage of the development of the Kama area with Neolithic pottery. At the late stage (as a result of interaction with the societies of the Middle Volga area), the ornament remained the same, and the technology for production of vessels changed and became mixed with the Middle Volga traditions.

6 THE FIRST POTTERS OF EASTERN EUROPE: TECHNOLOGICAL TRADITIONS AND CULTURAL CHOICES

**Abstract author(s):** Dolbunova, Ekaterina (The State Hermitage museum) - Kulkova, Marianna (Herzen State Pedagogical University of Russia) - Mazurkevich, Andrey (The State Hermitage museum)

**Abstract format:** Oral

One of the oldest groups of pottery in Eastern Europe date back to the 6th millennium BC. Early ceramics appeared in different regions in the steppe, forest-steppe and forest zones, mainly around tributaries of major water basins - the Volga, Don and Dnieper River. They belong to different local archaeological cultures. The striking similarity of certain features, and the proximity of the chronology, may point to some networks that existed at that time. However, the peculiarity of the ‘chaînes opératoires’ preserved in these different complexes may point to local technological traditions that might have been shaped by certain cultural choices. It becomes particularly clear when comparing it with complexes from other regions. This paper will present reconstructed ‘chaînes opératoires’ for some of the earliest ceramic assemblages of the steppe zone - Lower Don basin and forest zone - Dniepr-Dvina basin. The results of petrographic analysis of ca. 300 vessels will also be presented. The study of the raw material used for the production of vessels allows us to suggest cultural choices and certain adaptation to local raw material sources, which manifested in a change of raw material sources selection or in the search of paste recipes closest to customary recipes.

7 THE EARLIEST POTTERY ON THE TERRITORY OF SOUTH-EAST BELARUS: MAIN FEATURES AND WAYS OF PENETRATION

**Abstract author(s):** Tkachova, Maryia (Institute of History NAS of Belarus)

**Abstract format:** Oral

The beginning of the Neolithic period in Eastern Europe is associated, mainly, with the advent of ceramic production. For this reason, the earliest pottery, which carries information about the ways of penetrating new ideas, and, sometimes, the population in the region, has a particular importance for research. A comprehensive multistage analysis of the ceramic allowed distinguishing the most ancient vessels in South-East Belarus.

Technological features, morphology and ornamentation made it possible to classify this pottery as the pottery of the Strumel-Gastiatin type. Such ceramic was found on the settlements in the interfluve of the Dnieper and Desna.

Among researchers there is no consensus about the origin of the Strumel–Gastiatin type. However, it is still possible to talk about the origin of ancient pottery in the territory of South-East Belarus from the “south pottery centre” that has developed in the south-western region of Eastern Europe - in the area of the Bug-Dniester culture.

The data may indicate the penetration of the bearers of the early pottery making traditions on the territory of South-East Belarus by the “southern” way (by the Dnieper River from the south to north). The “eastern” way (by the Desna River from the east to west) seems less possible.

8 FROM THE MOMENT OF CREATION TO THE FUNERAL RITE - CERAMICS FROM NEOLITHIC CEMETERIES ON THE MIDDLE AND LOW DNIEPER

**Abstract author(s):** Andriiovych, Marta (Institut für Archäologische Wissenschaften)

**Abstract format:** Oral

Neolithic ceramic is one of the areas of big research interest. First pottery production caused a big influence on everyday humans’ lives... Including the last funeral ritual.

The Neolithic ceramic from Azov-Dnieper, Dnipro-Donetsk, Surska styles impresses with rich ornamentation made on full vessels body including the inner part of the rim and bottom. The variability of the ornamentation shows the interaction between social groups in the region. The same pottery was following the human throughout his life and probably was a valuable and respectful thing. The comparison of the pottery from settlements and cemeteries would give us a more complete understanding of the place of Neolithic vessels in the society, as well as how pottery was developed and change. The analyses of the main vessels’ types, styles, and correlation with different ornamentation techniques and ornamentation plots present us a full picture of the pottery development and human interaction in the region.

9 POTTERY IN THE ERTEBOELLE CULTURE – ORIGINS, PRODUCTION AND IMPACT ON MESOLITHIC DAILY AND SOCIAL LIFE

**Abstract author(s):** Meyer, Ann-Katrin (University of Hamburg)

**Abstract format:** Oral

The earliest pottery in Northern Germany and Denmark appeared between 4700 and 4500 BC within the late Mesolithic Erteboelle Culture.

Until today it has been subject to many typological analyses and to extensive studies of food crusts. However, a detailed analysis of the role of pottery within the development of Mesolithic society and economy or its influence on the Neolithisation process has been lacking.

This contribution, based on a recent PhD completed at Hamburg University, aims to shed light on the reasons behind the initial adoption of pottery technology as well as on use and function of the first pots and the ways the new technology spread. Using entanglement and agency theory, the paper addresses how form and function of the containers are connected to each other, if the function of pottery changed over time and if the technology arrived fully developed or underwent some “re-invention”. Another focus lies on the impact pottery had on Mesolithic daily life as well as on a development towards a complex society and on the Neolithisation process.

The results show that Erteboelle pots are characterized by a distinct shape, decorations and manufacturing techniques showing close proximity to (Eastern) Baltic hunter-gatherer groups in Poland. The pots are mainly connected to domestic activities with a strong emphasis on cooking aquatic resources whereas there a very few indications for functions related to prestige and status.

However, the newly created dependences and dependencies between people, pots and aquatic (marine) resources shaped Erteboelle life at various (social, cultural, economic etc.) levels and influenced patterns of mobility as well as formerly established structures of social complexity which paved a way to a Neolithic mode of subsistence.

10 KNOWLEDGE TRANSFER IN NEOLITHIC CERAMICS OF THE BALKANS AND EUROPEAN RUSSIA – A PATTERN

**Abstract author(s):** Spataro, Michela (British Museum) - Vybornov, Alexander (Samara State University of Social Sciences and Education) - Bacvarov, Krum (National Institute of Archaeology & Museum of the Bulgarian Academy of Sciences, Sofia)

**Abstract format:** Oral

Systematic archaeometric analyses have shown a variety of ceramic chaîne opératoire systems present in European Neolithic societies, but it is not always easy to detect craft transmission between neighbouring areas. Some natural barriers, such as mountains and

rivers, seem to act as boundaries for different cultural groups, e.g. the early Neolithic Impressed Ware communities of the Adriatic and the Starčevo-Criș-Körös and Karanovo groups in the Balkan peninsula. However, in the middle/late Neolithic, the pottery

produced throughout this region was superficially similar, although the technological choices were different. In some cases, previous traditions were maintained, and in others, most of the steps of the chaîne opératoire were replaced.

In this paper, a variety of ceramic chaînes opératoires will be discussed, emphasising the correlation between places, social structures and craft knowledge transfer. By the 6th

millennium BC, pottery production in the Middle East was standardised, and had nothing in common with contemporaneous ceramic production in south-eastern Europe. By contrast, 6th millennium BC hunter-gatherer communities in European Russia made ceramics using multiple techniques, which varied geographically, and appear unrelated to those of the first farmers in the Middle East and south-eastern Europe. Is technological

exchange possible only when similar social systems are in place? Do different social/economic structures prevent the exchange of knowledge?

11 EARLY NEOLITHIC POTTERY AND POTTERS IN THE EASTERN BALKANS: EXPLORING THE BEGINNINGS

**Abstract author(s):** Dzhafvezova, Tanya (University of Oxford)

**Abstract format:** Oral

The precise starting point of incipient technologies is not necessarily always clear in many regions, including the Eastern Balkans. This territory provides an excellent opportunity to examine pottery beginnings and dispersal, the conformity to traditional approaches and the introduction of innovative pathways while spreading the new ceramic technology.

However, complexity arises from: missing links to known pre-ceramic predecessors; scanty data about the earliest sites; disparate perceptions regarding the reasons, the trajectories and the dynamics of Neolithisation, and so forth. Understanding Early Neolithic pottery production is thus inextricably intertwined with the analytical approaches towards the accessible ‘earliest’ materials and, essentially, the interpretations of results.

In this paper, the questions how the first pottery was made in the Eastern Balkan region and who the first potters were, are tackled by the application of thin section analysis and scanning electron microscopy. The clay fabrics and inclusions, surface treatment and especially the decoration are considered within cultural, social and environmental context, thus widening the research horizons.

12 EARLY POTTERS IN GREECE: THE CASE OF MAVROPIGI-FILLOTSAIRI

**Abstract author(s):** Bonga, Lily (unaffiliated)

**Abstract format:** Oral

The Early Neolithic site of Mavropigi-Fillotsairi in Western Macedonia, Greece is one earliest ceramic sites in Southeastern Europe, and its location at a natural geographic crossroads makes understanding how and why ceramic choices were made all the more important as they relate to surrounding areas (local and extralocal). Both the technological details of vessel construction (e.g., tempering choices) and decoration (e.g., plastic, painted) demonstrate extensive and sustained interaction with surrounding communities. These choices demonstrate both external influences as well as independent innovation. Like most sites, the first ceramic forms

are technological simple and unelaborated, but unlike some early pottery in Western Eurasia, Early Neolithic pottery in Greece is not considered to be used for cooking or even food processing.

The ceramics from Mavropigi-Fillotsairi demonstrate that the choices in the production and uses of ceramic vessels were primarily driven by social and cultural needs. These choices, however, were also a result of historical trajectory of the spread of pottery, particularly the environmental constraints encountered by people moving further into the continent. Mavropigi-Fillotsairi provides an excellent opportunity to investigate how different aspects of ceramic production (including technology, morphology, and decoration) were changed or maintained as pottery was dispersed both in Northern Greece.

395 **WHO WERE THE FIRST POTTERS? CURRENT RESEARCH IN EARLY POTTERY PRODUCTION IN WESTERN EURASIA. PART 2**

**Theme:** 6. Material culture studies and societies

**Organisers:** Spataro, Michela (The British Museum) - Dolbunova, Ekaterina (The State Hermitage Museum) - Mylnikova, Liudmila (Siberian Branch Institute of Archaeology and Ethnography of the Russian Academy of Sciences)

**Format:** Regular session

Pottery appeared throughout this huge territory, between Western Siberia, the Mediterranean and the Atlantic Ocean, between c. 8000 and 4000 cal BC, following different trajectories, cultural choices and needs.

We are interested in how the first pottery was made throughout western Eurasia, and particularly in links between technological, morphological and decorative traditions in different regions. We welcome contributions based on interdisciplinary research, using archaeological evidence, ethnoarchaeology and archaeological science, and addressing questions including:

- Was the first pottery always technologically unelaborated?
- Was the chaîne opératoire of the first pottery determined by environmental constraints, economic and demographic factors, or the historical trajectory of the spread of pottery?
- Were early pottery forms based on existing container shapes or new functional requirements?
- How significant is decoration in explaining the spread of the earliest pottery in Eurasia?
- How were different aspects of ceramic production (technology, morphology and decoration) changed or maintained while pottery was dispersed?

**ABSTRACTS:**

1 **EARLY NEOLITHIC POTTERY AT SCHELA CLADOVEI. A COMPARATIVE STUDY OF ARCHAEOLOGICAL AND EXPERIMENTAL VESSELS FROM THE PERSPECTIVE OF COMPUTED TOMOGRAPHY**

**Abstract author(s):** Opris, Vasile (Bucharest Municipality Museum) - Boroneant, Adina ('Vasile Pârvan' Institute of Archaeology) - Petruñeac, Marta - Focsaneanu, Marin - Sirbu, Robert - Constantin, Florin ('Horia Hulubei' National Institute of Physics and Nuclear Engineering) - Bonsall, Clive (University of Edinburgh) - Golea, Mihaela ('Vasile Pârvan' Institute of Archaeology)

**Abstract format:** Oral

Traditionally, studies of Early Neolithic pottery in the Iron Gates region have focused on relative chronology based on shape and decoration characteristics. In recent years, technological approaches have become more common, reflecting the growing interest among archaeologists in the processes underlying the transition from hunting and gathering to farming.

However, many technological questions remain unanswered. Our paper offers a fresh insight into the Starčevo-Criş pottery from Schela Cladovei based on the application of computed tomography (CT) to obtain cross-sectional images of both archaeological and experimental vessels. The pottery experiments were conducted in the summer of 2019 at Schela Cladovei, while the CT scans were performed at the Horia Hulubei National Institute of Physics and Nuclear Engineering in Bucharest. The key feature of this study is a comparison between the characteristics of the archaeological and experimental pottery as observed in the CT images. The study takes into account the quantity and quality of technological variables such as voids, natural inclusions, vegetal tempers, forming techniques and surface finishing.

2 **DIVERSIFICATION OF POTTERY STYLES AS A RESULT OF MULTICULTURAL CHANGE DURING THE MID-6TH MILLENNIUM BC IN THE SOUTHERN CARPATHIAN BASIN**

**Abstract author(s):** Botic, Katarina (Institute of Archaeology, Zagreb)

**Abstract format:** Oral

Relative uniformity of the early Neolithic pottery stiles in the southern Carpathian Basin by the mid- 6th millennium BC saw a swift change. This change occurred in all the aspects of pottery production, from vessel shaping and decoration to the techniques of firing, recognized as various pottery styles in the archaeological records. Change in pottery styles accompanied diversification of other aspects of archaeological cultures such as house construction, husbandry, agricultural practices, flint production, etc. On some sites degree of hybridity in pottery styles is noticed.

3 **TECHNOLOGICAL CHARACTERIZATION OF NEOLITHIC POTTERY FROM THE SITE OF LUGO DI GREZZANA (VERONA – ITALY)**

**Abstract author(s):** Ciela, Marika - Tavella, Andrea - Pedrotti, Annaluisa (LaBAAF - University of Trento)

**Abstract format:** Oral

This summary reports the results of the ceramic paste and manufacturing analysis related to the Neolithic site of Lugo di Grezzana (Verona, Italy). The site is located in the Lessini Mountain and dated between 5400 and 4900 – 4800/4700 BC cal, which material culture is principally attributed to Fiorano culture and Vhò group. The aim of the study is to reconstruct part of the chaîne opératoire of XIII area of the site.

The ceramic paste analysis was initially carried out through the macroscopic observation of the inclusions with the aid of a stereomicroscope. Subsequently, 27 potsherds were selected, which thin-sections were observed under petrographic microscope. The evaluation of the nature and higher frequencies of the inclusions allowed to classify the fabrics into four groups. About manufacturing analysis, fashioning and finishing techniques were observed by low-angled light in order to detect diagnostic traces on surfaces, sections and in the fracture networks. The interpretation of the ceramic record was obtained by comparing with experimental and ethnographic data.

The results were compared to typological classification and stratigraphic evolution of the site. The ceramic paste and manufacturing analysis highlighted, in the last phases of frequentation, some technological changes such as bone tempered fabric and handle with tenon. Both confirm what has already been observed in the typological classification, with a partial contemporaneity between the Fiorano and early phase of Square Mounted Pottery culture (5000 – 4800/4700 BC cal). The results of the technological analysis provide new research data, not only for the site of Lugo di Grezzana, but in general for Early Neolithic ceramic production in northern Italy.

4 **YOU WILL KNOW THEM BY THEIR POTTERY... THE POTTERY OF THE EARLY NEOLITHIC (5700- 4700 BCE) IN THE WESTERN MEDITERRANEAN**

**Abstract author(s):** García-Martínez De Lagrán, Íñigo (UNED) - Molina, Lluís - Bernabeu, Joan (Universitat de Valencia) - Manen, Claire (CNRS - Université de Toulouse-Jean Jaurès) - Rojo, Manuel A. (Universidad de Valladolid) - Arcusa, Héctor - Laborda, Rafael (Professional Archaeologist)

**Abstract format:** Oral

This paper presents the first data on the ceramic style of the main sites located in the south of France, and in Spain in the Ebro Valley, Catalonia, the Northern Plateau and the Valencian Country. This research is part of an R+D+i project (PGC2018-100007-A-I00) of the Spanish government and aims to give a new vision of the Neolithisation and early Neolithic process of this wide area through the ceramic style as the main interpretative tool. This paper will present an overview and preliminary data from a study that is still in progress. For this reason, we will focus on certain global aspects such as techniques and the zonation of the decoration on the vessels, without analysing the specific cases of each site. We will also provide a general chronological framework of the main styles defined at this time and in this geographical framework. These styles will also be analysed from the perspective of the different types of archaeological sites and contexts.

5 **ORIGIN AND SPREAD OF ANTHROPOMORPHIC-POT FROM THE NEAR EAST TO EUROPE BETWEEN THE 7TH-6TH MILLENNIUM BC**

**Abstract author(s):** Bersani-Pancheri, Monica - Pedrotti, Annaluisa (University of Trento)

**Abstract format:** Oral

Through the analysis of anthropomorphic-pot (face-vessels and vessels with anthropomorphic depiction) our aim is to contribute to the understanding of the spread of this phenomenon from the Near East to Europe, with a particular focus on the Italian Peninsula, between 7th-6th millennium BC. Most of the data presented in this paper arise from a PhD project, completed in 2019. The research has taken advantage of important summary works that have studied human representation, both on vase and in the round, over vast areas, among which the works of Svend Hansen (2007), Valeska Becker (2011) and Heiner Schwarzberg (2011) stand out for their systematicity and breadth. The survey has concerned the examination of 927 specimens from 229 sites, belonging to the cultures attested between Mesopotamia, the Rhine river and Italian Peninsula. Starting from Anatolia, the obtained results allowed us to establish two distinct 'routes' of dissemination, reconstructed by the absence or presence of certain iconographic patterns, according to a hypothesis that would be confirmed by the chronological sequencing of the 14C dates of the finds:

- a 'continental route' to the north which, through waterways flowing into the Aegean, reaches first western Bulgaria, between 6000 and 5900 BC (Karanovo I), and then the heart of Europe, arriving in Serbia (Starčevo) and central Hungary (Körös) around 5800-5500 BC;
- a westward 'sea route' involving first Thessaly, between 6200 and 6000 BC (Protosesklo), and then Apulia (Guadone),

around 5800-5650 BC.

In the Italian Peninsula anthropomorphic-pots are not evenly spread, they do not cross the boundary defined by the Apennine Range, and their diffusion from south to north occurs only in the eastern part of the peninsula, arriving in northern Italy around 5300 BC. Face-vessels are mainly concentrated in south-eastern Italy, while anthropomorphic depiction on vase characterize the early Neolithic in the Po Valley.

### ADDED TEMPERS AND WAYS OF DOING IN THE FIRST POTTERY PRODUCTIONS

**Abstract author(s):** Clop García, Xavier (ARCHAEOM, Department of Prehistory, Autónoma de Barcelona University)

**Abstract format:** Oral

The treatment of clays is one of the first work processes carried out in the pottery production process. Once the clays have been transported to the place where the ceramics are made, they are treated by developing various operations (fragmentation or crushing of the clay; granulometric selection to homogenize, to a certain extent, the size of the minerals components; elimination of large mineral elements or visible plant elements; etc.) in order to obtain an optimal raw material for carrying out the rest of the work processes necessary to produce pottery.

In the treatment of the raw material there is also an optional operation: the possible addition of some type of added temper. In many cases in different parts of the world and in different periods, characterisation studies show the deliberate addition of temper to pottery in the form of minerals/crushed rocks (e.g. talc, calcite, chert), organics (e.g. vegetable matter, bone fragments, shells) or anthropogenic materials (e.g. grog).

This communication presents a systematized view of the added tempers documented in the framework of the first pottery productions in the Near East and the Mediterranean basin. Carrying out a large number of archaeological characterization studies allows us to start proposing global visions that allow us to know the specific characteristics of the use of added temper in the first productions of this entire area and to raise and discuss issues such as specific chronological frames the use of the different types of added temper, their role in the context of the ways of doing and their transmission, the relationship between their use and the functionality of the pots, etc.

7

### TECHNOLOGICAL TRANSFER IN PRODUCTION OF MAJIAYAO-STYLE POTTERY BETWEEN NEOLITHIC COMMUNITIES IN NORTHWEST CHINA

**Abstract author(s):** Dammer, Evgenia (University of Oxford; The British Museum, Department of Scientific Research)

**Abstract format:** Oral

The present paper discusses the transfer of technological knowledge for making the Majiayao-style pottery in Neolithic China (5300-4000 BP). The Majiayao-style is known for its elaborate painted designs in monochrome black or in black and red on large globular vessels made of fine clay, and for the coarse pottery decorated with cord impression and appliqué. The Majiayao-style pottery was widely distributed in prehistory across different river valleys located hundreds of kilometres away from each other. This study investigates whether there are similarities in making technology of the Majiayao-style beyond the shape and decoration and addresses communication and connectivity of prehistoric people living in different river valleys.

The methods of macroscopic examination, ceramic petrography and experimental firing of raw materials were used to reconstruct the chaîne opératoire of the Majiayao pottery from four sites. The results of this study revealed parallels in materials and techniques for making this pottery in different locations indicating common technological knowledge that could have been disseminated among potters. Furthermore, the combination of macroscopic and microscopic analysis has shown that there are patterns in connection between the coarse and fine clay fabrics with specific decoration and firing atmospheres. The observations suggest that beside the technological knowledge, the making of Majiayao-style pottery also required specific social knowledge to connect outer appearance of the Majiayao-style with the production materials and techniques. This paper concludes that the two contrasting fabrics - coarse and fine, and surface textures - rough and smooth - need to be considered together in order to address issues of prehistoric technology and shared social knowledge in Neolithic northwest China.

8

### COMPARATIVE ANALYSIS OF CERAMICS THE VOLOSOV CULTURE OF THE UPPER AND MIDDLE VOLGA REGIONS (BASED ON TECHNICAL AND TECHNOLOGICAL ANALYSIS)

**Abstract author(s):** Andreeva, Olga (Samara State University of Social Sciences and Education)

**Abstract format:** Oral

The Volosov Eneolithic culture was identified in the Middle and Upper Volga regions at the beginning of the 20th century. Its chronological framework falls within the interval from 4100 to 2800 BC. Vessels with a rounded and flat bottom are ornamented over the entire surface, less often along the outer and inner sides of the rim with large non-ornamented zones. The ornamental elements presented are toothed and comb impressions, frame stamp; rope and pits. The study of the ceramics manufacturing technology was carried out according to the method developed by A.A. Bobrinsky, based on the study of skills (stable methods of performing work) with the help of which the dishes were made.

The ceramics of the Volosovo culture of the Middle Volga region (121 vessels) and the Upper Volga region (28 vessels) were analyzed. For the manufacture of dishes, silty clay was used as the initial plastic raw material: Middle Volga region 98%, Upper Volga region

100%. The following artificial additives were used: chamotte (CH), organic solution (OS), crushed shell (CS), and down-feather of a bird(F). The potters of the Upper Volga region made up the molding mass according to two recipes: OS+F 29%; OS + CS + F 71%. The population of the Middle Volga region applied six ones: OS+F 55%; OS+CH+F 20%; OS 11%; OS+CS+F 10%; OS+CH 3%; OS+CH+CS 1%.

For the Volosov population, the admixture of organic solution is persistent while the introduction of chamotte and crushed shell into the molding mass is the most archaic tradition associated with the early stage of culture. The admixture of down-feathers of birds might be due to the mixing of the population at the later stages of the development of the Volosov culture.

The research has been carried out with the grant from the Russian Science Foundation (project 19-78-10001).

9

### TECHNOLOGICAL VARIABILITY IN THE EARLY CHALCOLITHIC POTTERY PRODUCTION FROM EASTERN ROMANIA

**Abstract author(s):** Matau, Florica (ARHEOINVEST Center - Science Department, Interdisciplinary Research Institute, Alexandru Ioan Cuza University of Iasi)

**Abstract format:** Oral

The aim of this study is to identify how the Precucuteni ceramic artefacts (5050-4600 cal BC) were produced in order to diagnose the imposed constrains caused by the selected raw materials. Further, we will explore the solutions advanced by the potters both at the level of raw material selection and at the paste preparation and vessel firing.

The morphological analysis based solely on visual inspection and complemented only with typological and stylistic analysis is not sufficient to determine the variation present in the paste recipes and in the raw materials. In order to address the above-mentioned issues a combination of archaemetric techniques is necessary.

Until now, only two studies were dedicated to the investigation of technological features of a small number of Precucuteni pottery identified at Târgu Frumos (Ellis, 2005) and Târpești (Mățău et al., 2019). Both studies mentions the existence of at least two recipes for pottery making and the constant experimentation with reducing conditions combined with a tendency to experiment firing in oxidizing atmosphere.

This study aids five more sites located in the eastern part of Romania aiming to evaluate the pottery chaîne opératoire and examine the correlation between pottery production, chronological and regional variability. We undertook visual examinations of the manufacturing techniques combined with thin-section petrography and X-ray powder diffraction (XRPD) for a more accurate estimation of the firing variability.

### EARLY NEOLITHIC CERAMICS OF THE BARABA FOREST-STEPPE: INSTRUMENTAL ANALYSIS

**Abstract author(s):** Mylnikova, Liudmila - Molodin, Vyacheslav (Siberian Branch Institute of Archaeology and Ethnography of the RAS)

**Abstract format:** Poster

At the multilayer sites Tartas-1, Ust-Tartas-1, Vengerovo-2, Avtodrom-2/2, a new complex of the Early Neolithic era (late VIII-early VI millennium BC) was identified, which was named the Barabinskaya culture. These are the earliest objects in Western Siberia containing pottery. The ceramic collection has undergone binocular, petrographic and thermal analyzes. Low-sand ferruginous loams of montmorillonite-hydromica composition were used as a raw material. Revealed the use of two sources of raw materials, which, in addition to the above, included chlorite-hydromica medium sandy loam. One recipe for molding materials is fixed: loam + sand + chamotte + organic solution. The vessels were molded on a base mold using a capacitive filling. An ordered two-three-layer flap acts as a building element. The upper part of the vessel was molded separately with two strips composed of a two-layer flap. A thin twisted cord was superimposed on the upper edge, which was then covered with a ribbon of patches bent inside the vessel. Channels from the burnt-out strapping cord are fixed on the fracture of all the rim fragments. The bottom - the cake was also made using patchwork technique, inserted into the finished form and attached to the body with small patches, as a result of which a roller was formed around the perimeter. The ornament is represented by a complex subject composition covering the entire surface of the vessel including the bottom. The assignment to this culture of similar in appearance sites of modern Kazakhstan and the Ishim region requires additional research, since in these territories there could also be local cultural groups that had their own specifics, but made flat-bottomed dishes.

With a high degree of probability it can be assumed that the origins of this culture can go back to the culture of the local Pleistocene.

**Theme:** 1. Widening horizons through human-environment interconnections  
**Organisers:** Panagiotakopulu, Eva (School of GeoSciences, University of Edinburgh) - Sigl, Johanna (Kommission für Archäologie Außereuropäischer Kulturen - KAAK)  
**Format:** Discussion session

Environmental change either as a result of human impact or climate change has a long history in the Nile valley. From the much discussed Old Kingdom collapse to a variety of apparently catastrophic events and more nuanced incremental change, the archaeological record, with unique information from organic remains, resulting from optimal preservation, provides a detailed body of data. These allow refined interpretations for past events, including societal change. The session aims to present case studies from archaeological and palaeoenvironmental research, combining novel techniques and established approaches, theories and data in an attempt to engender a holistic approach to change in the Nile Valley during the Holocene, in particular during the last 10.000 years. We shall look into results on environmental change from different research methods in order to obtain a multidisciplinary perspective. The session will range from detailed site interpretations to key events and moments in time, from droughts, extinctions and changes in agriculture, famine, disease, trade networks and biogeographic change. We shall approach the problems and datasets with a view to using knowledge of the past to understand also present change.

**NILE FLOODS DURING THE LAST AFRICAN HUMID PERIOD: A SEASONAL RECORD FROM THE DEEP-SEA FAN**

**Abstract author(s):** Blanchet, Cecile - Arne, Ramisch - Rik, Tjallingii - Achim, Brauer (GFZ Potsdam)

**Abstract format:** Oral

Seasonal floods are life-supporting events in the Nile Valley and have been crucial to the development of complex societies. Present populations depend on their occurrence but the alteration of fluvial dynamics under climate change remains elusive. In order to better understand how fluvial dynamics respond to climatic changes, we explore past flood dynamics of the Nile River using a unique finely laminated sequence from the Nile deep-sea fan.

Today, floods occur during the summer, when monsoonal rainfall hits the Ethiopian highlands and feeds the Blue Nile. Core P362/2-33 covers the past 9.5 ka BP and is ideally located to record changes in fluvial dynamics during periods of stronger monsoon activity such as the Saharan Humid Periods. The absence of oxygen in the Mediterranean bottom waters during the last Saharan Humid Period (during sapropel S1 deposition) allowed to preserve the laminated structure between 9.5 and 7.5 ka BP.

We focus here on examining the nature of the laminations in order to 1) understand the deposition mechanism and 2) obtain a reconstruction of past fluvial dynamics at seasonal resolution.

Microfacies analysis and elemental micro-XRF scanning indicate that couplets of alternating dark- and light-coloured layers represent seasonal deposits of Nile discharge and marine hemipelagic sedimentation, respectively. Preliminary lamination counts suggest that couplets were deposited at an annual rate for most of the record. Increases in layer thickness is observed around 9.5 and 9.1 ka BP, followed by a gradual decrease until 8 ka. Careful examination of lamination structure and time-series analysis of layer counts will permit to further explore sub-annual changes in flood dynamics during the Saharan Humid Period. Finally, due to its high temporal resolution, our record has the potential to link reconstructions of Nile discharge to other regional archives of hydrological changes (e.g., speleothems, lakes) and thereby identify overarching forcing mechanisms.

**CHANGING DESERT LANDSCAPES: PAST AND PRESENT LAND USE IN THE NORTHERN DONGOLA REACH, SUDAN**

**Abstract author(s):** Sevara, Christopher (Newcastle University) - Minor, Elizabeth (Wellesley College) - Fera, Martin (University of Vienna) - Oliver, Kalei (Wellesley College) - Schellinger, Sarah (Ohio State University) - El-Hassan (Sokhari), Ahmed (National Corporation for Antiquities and Museums, Sudan)

**Abstract format:** Oral

Social and environmental changes had significant impacts on lifeways of Nilotic communities as the African Humid Period came to an end. Since that time, people have employed various strategies to cope with climate change, population increase, and shifting socio-political influence. Adaptations in Human Landscapes Along the Nile (AHLAN) is a new multidisciplinary landscape research project focused on understanding how people developed such strategies through a study examining the development of rural agricultural and transport infrastructures in the region near modern-day Dongola, Sudan. Prior research indicates infrastructure development occurred around former river channels as climate and social change necessitated innovative strategies for sustainability. AHLAN is investigating these traces using data from new remote sensing technologies, geospatial analysis, and community engagement to better understand how these developments contributed to the growth and decline of local and regional settlement networks over time. In this paper, we present our initial work with AHLAN, discussing the new contributions analysis of remote sens-

ing data can make to our current understanding of the regional archaeological and paleoenvironmental record, including the impacts from recent rapid modern agricultural development on archaeological resources.

3 CLIMATE CHANGE, HUMAN IMPACT AND INSECT FAUNAS FROM THE NILE VALLEY

**Abstract author(s):** Panagiotakopulu, Eva (School of GeoSciences, University of Edinburgh)  
**Abstract format:** Oral

The scale of human impact in the Nile Valley has accelerated with intensification of settlement and increasing population from the pharaonic period onwards and at least since the Roman period human impact significantly altered natural environments. Such impacts, from grazing pressure to storage loss and disease can be traced in changes in the insect fauna, and the frequent survival of fossil assemblages in archaeological contexts as a result of desiccation provides one source of this information.

Based on ongoing insect research from sites in the Nile Valley this paper will discuss changes in the insect fauna during the pharaonic and the Roman period and how these may relate to climate change and human impact. Results so far indicate environments different to the contemporary desert one further away from the Nile, with presence of dung beetles associated with large herbivores and perhaps large herds, including scarabaeids, even from urban contexts. Taxa representative of pests of stored products increase during the New Kingdom. Their diversity further increases during the Roman period, when new species are introduced in the Nile Valley, a direct result of movement of armies and long distance trade networks. Although insect results are context and site specific, current data indicate that there is a change in diversity of the assemblages over time and past environments differ significantly from modern ones.

**Theme:** 5. Assembling archaeological theory and the archaeological sciences  
**Organisers:** Kreiser, Jane - Lang, Franziska (TU Darmstadt) - Grobe, Lars (Lucerne University of Applied Sciences and Arts) - Brünenberg, Clemens - Noback, Andreas (TU Darmstadt)  
**Format:** Regular session

Digital methods and tools in analyzing archeological data, complemented by computational simulation, offer new opportunities in the research of the interdependence of humans and buildings. We will focus on the intangible building environment and its effects on human practices, namely in the domains of

- building physics, e.g. heat transfer, lighting and daylighting, and acoustics,
- perception, e.g. visual, tactile, and spatial perception,
- changes in building practices, e.g. the advent of new technologies.

The question arises whether and how e.g. simulation, mixed realities, algorithms, and artificial intelligence change scientific processes and impact the archaeological epistemology. For example, complex human-thing relationships, which are theoretically anchored in concepts such as agency (affordance, entanglement etc.) are suitable for testing the effects of extensive data and computational simulations of building environments on the knowledge process.

We invite researchers working with a genuinely digital approach in the field of architecture and/or building environment to discuss and to critically evaluate how the use of digital methods reflects, extends or changes the objectives, practice, and theory formation in archaeological research.

The aim of this session is to achieve a deeper understanding of the new opportunities – and challenges – in digital research and to sharpen up the interdisciplinary archaeological objectives in theory, terminology, methodology and technology.

**AFFORDANCE-BASED ANALYSIS OF DAYLIGHT IN ANCIENT HOUSES BY MEANS OF SIMULATION**

**Abstract author(s):** Lang, Franziska - Kreiser, Jane - Hollaender, Julian (Department of Classisal Archaeology, TU Darmstadt)

**Abstract format:** Oral

Previous scholarship on ancient housing addresses furnishing, function, and activities within houses. Widening the primary focus on architecture and finds from individual rooms leads to questions regarding the social structuring of houses. Light, sound, smell & other aspects of the sensory perceptions of space are considered only recently. Due to their immateriality, these cognitive phenomena can be analysed through new technologies. Computational simulation techniques and methods lend from computer graphics in particular now enable researchers to approach the immaterial phenomena of the past.

Our project complements such investigations by taking account of daylight and its role in ancient houses. Daylight is a variable phenomenon affecting visual perception; it is therefore a particularly potent parameter of interaction enabling, causing or limiting social, technical and cultural activities. The availability of daylight structures and determines multimodal options of usage (affordance) of the built environment in the course of a day or a year. Daylight thus takes on an object-like character. To reconstruct daylight as an agent connected with possible uses and social interactions in houses and make it measurable in the architecture context, we use

digital reconstruction methods and computer simulation in an interdisciplinary project approach. In this multidisciplinary project, the significance of daylight for the ancient inhabitants is also recorded by evaluating ancient written sources and compared and validated with archaeological-architectural results and computer simulation. Analytical-empirical and experimental methods are networked in a complementary way.

## 2 MODELLING KNOWLEDGE. ON INTRODUCING DYNAMIC RECONSTRUCTION AS A TOOL TO INVESTIGATE THE USE AND PERCEPTION OF BUILT ENVIRONMENT

**Abstract author(s):** Brünenberg, Clemens - Mächler, Claudia (TU Darmstadt, Faculty of Architecture, Institute of Classical Archaeology)

**Abstract format:** Oral

The determination of the scientific value of 3D reconstructed architecture is a controversial and widely discussed topic. In most cases, however, this discussion is based on individual, fixed reconstructions or at most a small number of variations. At the same time, extensive 3D models are usually only created at a very late stage of the project or even after the end of a research project, which suggests that their scientific value is still primarily within their visual effect. Therefore, in most cases the reconstruction does not directly influence the scientific objectives itself.

This paper discusses a novel practice to linking the process of modelling directly to the knowledge process with a parametric approach. Thereby, our starting point is neither the visualisation of an ideal reconstruction nor a final research result, but rather examine how built environment could be used and perceived depending on a large range of reconstructed situations. Within the reconstruction process and therefore the knowledge process we seek to generate dynamic variations of the reconstruction (e.g. room height, number of windows, etc.) by defining parameters of which this dynamic reconstruction is based on. We will discuss the general approach of finding, defining, and describing these parameters for this novel method of reconstruction and present a case study in which it is examined how daylight influences the dynamic reconstruction of built spaces and vice versa.

## 3 A MODEL CHAIN TO SIMULATE DAYLIGHT IN HISTORIC BUILT ENVIRONMENTS

**Abstract author(s):** Noback, Andreas (Technical University of Darmstadt) - Grobe, Lars - Schuetz, Philipp (Lucerne University of Applied Sciences and Arts)

**Abstract format:** Oral

The simulation of daylight in buildings of the past, based on archaeological record, and its interpretation in the context of human history is a field of interdisciplinary research. It relies on a consecutive combination of models, that emerge from different disciplines and are possibly based on diverging assumptions. Each of these models comes with its particular capabilities, limitations and uncertainties. This contribution distinguishes four major model domains: 1. Architectural reconstruction reflects historic practice and provides a geometric representation of the evaluated building in the past. 2. Models of building materials describe their interaction with light, e. g. scattering and absorption. They cannot just mimic the characteristics of an archaeological find but must deduce its state in the past, taking into account physical material properties and historic production methods. 3. Environmental conditions are defined by sky models. They must reflect the luminance distribution of the sky hemisphere and can integrate effects of external occlusion and reflection. 4. Perception models bridge the gap between the results of light simulation, e. g. in terms of radiometric or photometric quantities, and the subjective response of a human observer for the interpretation in the context of historic research. For each of these four model domains, an example is introduced and critically discussed. Structuring the interdisciplinary research along a chain of distinct models is proposed to foster the discourse between the disciplines. This shall provide a better understanding of the potential and uncertainties of daylight simulation in the research of production and perception of historic built environments.

## 4 LIGHT OF REASON: USING LIGHT SIMULATION TO INVESTIGATE A POMPEIAN HOUSE

**Abstract author(s):** Campanaro, Danilo (University of Lund)

**Abstract format:** Oral

Light played a key role in the Roman house, where daylight and flames were the only sources of illumination and warmth. Importantly, light (and darkness as its counterpart) deeply influenced other aspects of Roman society, effectively acting as a social agent. In this regard, the “social atmosphere” of domestic space was certainly affected by the lighting conditions. The owner might have intentionally leveraged on these aspects to bolster messages of wealth and power delivered to the guest. By means of historically based and physically accurate lighting simulations and analyses, this study investigates the intertwining of spatial and social patterns, in order to get new insights into social and spatial behavior in the Roman house under the influence of light. Notably, the adoption of such digital methods calls for new epistemological duties to ensure transparency of the processes. In this light, a point is also made that a pattern of reasoning, known as inference to the best explanation (IBE), can proficiently be used to build unitary hypotheses from complex and multifarious sets of data in a transparent way. Specifically, the proposed inquiry focuses on the case study of the House of the Greek Epigrams (V 1,18.11-12), located in the northern part of Insula V 1 in Pompeii.

## 5 ACOUSTICS AND PROXEMICS OF ROMAN ‘CONTIONES’

**Abstract author(s):** Kopij, Kamil (Institute of Archaeology, Jagiellonian University) - Pilch, Adam (AGH – University of Science and Technology in Krakow) - Drab, Monika - Popławski, Szymon (Wrocław University of Science and Technology) - Głomb, Kaja (Institute of Applied Psychology, Jagiellonian University)

**Abstract format:** Oral

In our paper, we present the results of an acoustic and proxemic analysis of selected speaking platforms from which Romans have spoken publicly at Forum Romanum. Our main goal was to determine the maximum number of recipients that were able to hear speeches intelligibly as well as see the gestures of an orator. Given that at the turn of the Republican and Imperial periods significant changes in the rhetorical landscape of the Forum took place, our goal was to study and compare speaking platforms in two periods: Late Republic (ca. 55 BCE) and Early Imperial (Augustan).

The analyses were conducted based on 3D virtual reconstructions of the structures taking into account the acoustic properties of the materials from which they were built. Using Catt-acoustic software we run simulations in order to establish Speech Transmission Indexes (STIs) for different background noise levels (between 36dBA and 55dBA). At the same time, we established maximal visibility of three different classes of rhetoric gestures based on the results of experiments we conducted.

Based on the results of acoustic and proxemic simulations (the areas of audibility and visibility) we estimated the crowd sizes using two different methods based on modern observations of the behaviour of crowds. As a result we:

1. estimated the number of people that could intelligibly hear a speaker and see his gestures for all case studies,
2. established what percentage of attendees (taking into account the maximum capacity of the available spaces) could hear the speaker intelligibly and see his gestures.
3. by comparing results for different rostra we showed that they had different acoustic properties depending on the level of background noise, which affects the maximum number of recipients. This in turn leads us to consider the awareness of speakers’ choice of rostra depending on the circumstances.

## 6 AURAL EXPERIENCES IN THE ARCHAEOLOGICAL SPACES: APPROACHES, METHODS, AND PERSPECTIVES

**Abstract author(s):** Bellia, Angela (Institute of Heritage Science - National Research Council of Italy)

**Abstract format:** Oral

The aural experience is a fundamental process in the development of human beings, which is shaped by architecture and the environment. Sensory experience has rarely been considered in the study of public spaces in antiquity. As Barry Blesser and Linda-Ruth Salter (2007) pointed out, aural architecture is that aspect of real and virtual spaces that produces a sensorial and behavioural response in inhabitants. For example, a performative space in antiquity related to a sanctuary can produce feelings of connectedness and a sense of numinous.

This paper aims to investigate new insights and a radical reappraisal of antiquity’s sounds and sights in a performative space. Furthermore, this paper will explore the visual and acoustic experiences in the performative spaces “as sensory artefacts” (Eleonor Betts, 2017), developing a new theoretical basis and linking digital heritage and acoustical techniques.

Through the acoustic analysis of particular case study in Italy, this paper will intend to explore a new approach to the development of the relationship between space, sound, and environment and a novel method to decipher geophony, biophony, and anthropophony, as a sort of “sonic fabric” (Steve Mills, 2015) of the performative spaces and their immediate surroundings, taking into account the relationships between the different and interactive sonic components of a landscape, thanks to digital technology.

## 7 SPACE SYNTAX AS A PRIMARY TOOL IN (RE)SHAPING OUR PERCEPTION OF THEIR PERCEPTION, AND INTENTION: THE CASE OF TURÉGANO CASTLE

**Abstract author(s):** López Lillo, Jordi A. (Institute of Heritage Sciences, National Research Council - Incipit-CSIC) - Yuste Burgos, L. Miguel (Caminos del Románico)

**Abstract format:** Oral

Despite its main theoretical body was developed several decades ago, the use of Space Syntax techniques and software in archaeological research on built environments only started to gain strength lately. In short, this approach poses that, if inhabiting a space is a way of segmenting it in culturally meaningful terms, then systemic analyses could be practiced in order to reveal the underlying non-discursive, mathematical structures of such “semantics”. Node analysis in particular constitutes a readily applicable tool for understanding circulation flows within buildings, while providing robust means to compare different layouts and distinguish genotypes. In the case of Turégano castle, originally a Romanesque church in Segovia Province (Spain) that underwent various fortification processes ranging from the 13th to 16th centuries, node analysis was implemented together with visibility graphs and agent-based movement simulations. The primary goal of this study was to experimentally test the feedback between stratigraphic reading of preserved wall faces and Space Syntax, as a way to approach the shape of the building following the last massive remodeling works. However, in doing so, not only specific functional areas and subsystems were detected –guest chamber vis-à-vis the main one, possible garrison location, visitor paths framed by multidimensional expressions of power, etc.–, but an extremely consistent defensive plan arose. The latter is particularly significant since the military intention of such remodeling has been discussed to a certain

extent, given its conspicuous representative function, and, foremost, its apparent obsolescence in a context of growing use of firearms. These results evidence therefore that simple computational tools placed in hands of Archaeology, and interpreted through its lens, can make a big difference in comprehending spatial perception from the point of view of historical agents. Sometimes even against our current experimentation of the very –only apparently– same spaces.

8 DIGITAL APPROACHES IN EXPERIMENTAL LEARNING. MARBLE AS A CASE STUDY

**Abstract author(s):** Miznazi, Diana - Stroth, Fabian (University of Freiburg)

**Abstract format:** Oral

The project MARBLE has been conceived to develop and test three-dimensional visualisation methods in archaeology higher-education teaching over the next three years. Using the smart augmented-reality glasses, students are able to virtually walk around and examine monuments, architectural elements and archaeological sites in the classroom and virtually visit sites that are normally not accessible e.g. due to their fragile state of conservation. New technologies used in the smart glasses offer the chance to perceive the model in an interactive, mixed-reality scenario. Thus, creating new conditions for teaching and research.

Although space has been tightly linked to human existence, digital representations of space are, in contrast, a fairly new medium, which is still developing its qualities of perception. This new medium has been adapted for the communication of historical architecture and archaeology. Current archaeological research has been intensively devoted to the development of digital tools and the produced large 3D data sets for the documentation heritage sites. However, archaeological university teaching is still characterized by a reduction of the investigated 3d objects to 2d images. In MARBLE, we focus on the potentials offered by technologies such as VR and AR in regard to a didactic integration into the object-related university teaching.

The latest AR technology offers to view objects in their spatial complexity, hence enhancing the learner’s perception and understating of archaeological and cultural heritage assets. The project MARBLE also aims at assessing the efficiency of using 3d models of cultural heritage sites, in the perception of archaeology and aspires to suggest best practice examples for future research. Moreover, MARBLE has the potential to make significant contributions to the current phenomenological aspects of architectural/archaeological research such as spatial perception.

During the course of this project, we aim to assess our innovative digital approach and identify its advantages and challenges.

409 ARCHAEOLOGISTS, SITES AND METHODOLOGIES: PROFESSIONAL AND PERSONAL NETWORKS IN MID-20TH-CENTURY EUROPE (PART 2)

**Theme:** 6. Material culture studies and societies

**Organisers:** Gramsch, Alexander (Römisch-Germanische Kommission - RGK) - Mytum, Harold (University of Liverpool) - Babić, Staša (Faculty of Philosophy, University of Belgrade)

**Format:** Regular session

At the EAA Virtual Annual Meeting in 2020 part 1 of our session addressed the professional and academic exchange in the decades before and after World War 2. In the follow-up session we want to – in accordance with the EAA 2021 conference motto – widen the horizon and to include further aspects and expand the time period under investigation. The post-war generations were indeed widening horizons and increasingly put the socio-political implications of archaeological interpretations on the agenda and discussed how archaeological results became used for political ends. This awareness culminated in archaeology losing its innocence. This conforms to Theme 6, seeing the changes in understanding of material culture and how it could be interpreted to reveal insights about past societies. Part 2 of our session on the 20th century history of archaeology thus addresses the rise and challenge to culture history in the mid-century and the attempts to develop New Archaeologies. We suggest considering on the one hand whether these developments lead to a split of research traditions across Europe into Western, Northern, Central, and Eastern European schools of thought or whether diverse traditions already existed before, and on the other hand whether or to what extent personal connections and institutional international links circumvented a split. Communication and exchange surely existed – but what was communicated: methods, theories, or results? And how far were these taken up? Did the 1960s and 1970s experience a loss of the previous European perspective, regained only in the 1990s? We encourage addressing individual biographies, institutional level networks, and trans-national to trans-continental research agendas.

ABSTRACTS:

1 AN INTRODUCTION TO PROFESSIONAL AND PERSONAL NETWORKS IN MID-20TH-CENTURY EUROPE

**Abstract author(s):** Gramsch, Alexander (RGK - Romano-Germanic Commission DAI)

**Abstract format:** Oral

With the political changes of the 1990s the interest in the history of archaeology increased, leading to a number of conference presentations and collected volumes. Two of the main issues debated were the impact of nationalism on the establishment of archaeology as a discipline in Europe in the late 19th century and the impact of the post-war political tensions in Europe on its development in the mid-20th century. Contemporary witnesses reported that personal networks were kept alive across the Iron Curtain,

while at the same time academic exchange was impeded by reduced travel opportunities and reduced exchange of publications on an institutional level. Introducing our session on the professional and personal networks in mid-20th-century Europe we want to take a fresh look on the development of new ideas and approaches in Western, Central and Eastern Europe, and on how post-war generations were increasingly putting the socio-political implications of archaeological interpretations on the agenda and discussed how archaeological results became used for political ends. We want to address the challenges to “culture-historical archaeology” in the mid-century and the attempts to develop New Archaeologies within various schools of thought. Opening the session we want to take a look at the schools of thought that existed before and after World War II, and on whether or to what extent personal connections and institutional international links circumvented a split along the Iron Curtain.

2 REVOLUTION OR MYSTIFICATION? REFLECTIONS ON ATTEMPTS AT SPREADING NEW ARCHAEOLOGY IN 1970S ENGLAND

**Abstract author(s):** Mytum, Harold (University of Liverpool)

**Abstract format:** Oral

The appearance of new archaeological theories can be stimulating or threatening. The conflicts in North America between culture historians and New Archaeologists were played out partly in print, and some of the venom is clear to read in journals and edited collections. In contrast, the British and European interactions largely remain undocumented in the public sphere. This paper takes an autobiographical approach to examine the New Archaeology challenge to culture history in Britain through the viewpoint of a young observer, not at that time strongly attached to a particular mode. Active in field archaeology and attending a variety of evening classes by University of Birmingham extra-mural staff whilst at school, the author experienced diverse views about what culture historical archaeology was about, and how it should be carried out. Attempts to spread David Clarke’s ideas regarding New Archaeology from Cambridge to the Midlands of England in the early 1970s exposed a young mind to an alternative paradigm. This presentation recalls and analyses this dissemination through the reading of Analytical Archaeology (1968) and a seminar at the University of Birmingham. The reactions of Birmingham University staff to the seminar, and the impact of the book and event on the presenter’s intellectual development and career path, are considered in the light of conservatism and innovation within UK academic and ‘Rescue’ archaeology through the 1970s. Archaeological fieldwork in the UK was not immediately transformed by New Archaeology, but a historical perspective now allows shifts in policy and practice to be seen in an evolving intellectual landscape. This established a fusion of processualism and culture history that became the dominant mode of discourse that is still reflected in many aspects of Historic England’s regional and national research frameworks.

3 INTERNATIONAL NETWORKS AND GEOGRAPHIES OF KNOWLEDGE IN EUROPE BEFORE AND AFTER WORLD WAR II

**Abstract author(s):** Díaz-Andreu, Margarita (ICREA; Universitat de Barcelona)

**Abstract format:** Oral

Since the late 1980s, sociologists and historians of science have drawn attention to the key role played by contingent historical factors in the creation of scientific knowledge. Science is seen not only as a cultural formation inserted into wider networks of social relations and political power, but, significantly, as also being shaped by the local environments or geographical locations in which it is produced. In this light this paper will analyze how scholars may be affected not only by ideas in their learned environment, but also by the social networks of their academic milieu in their close geographical area and beyond. To date, most of the studies that have investigated this issue have focused on the academic and personal links formed by colleagues who are frequently in contact. In contrast, this paper will critically explore the impact on science of the exchanges between scholars living in distant geographies, i.e., the impact of wider, international networks in the discipline.

The international scholarly networks established before and after World War II will be explored on the basis of the information gathered from several archives containing correspondence by three university professors, Luis Pericot (University of Barcelona), Gordon Childe (UCL) and Christopher Hawkes (University of Oxford). The information contained in letters exchanged between some of the main prehistorians after World War II up to the 1970s will be analyzed in order to reconstruct networks. Ultimately, the aim is to assess how these networks affected the development of archaeology from the 1940s to the 1970s.

4 THE ‘SWINGING SIXTIES’: NETWORKING ARCHAEOLOGY IN PORTUGAL

**Abstract author(s):** Martins, Ana Cristina (IHC - Polo da Universidade de Évora; UNIARQ - Universidade de Lisboa)

**Abstract format:** Oral

The 1960s and 1970s were of particular importance for the history of Portugal. It was then that the transition took place between the totalitarian regime of the ‘Estado Novo’ and the process of democratisation of the country brought about by the ‘Carnation Revolution’.

But despite such a complex political context, scientific production in the territory is deepened and expanded through state and private support, as well as following the implementation of international projects.

Archaeology was no exception. In fact, although in a reduced number, when compared to other areas of knowledge, we verify the public and private financing of research centres and projects, scholarships in the country and abroad, exhibitions, congresses, and publications.

More than that, there is a growing tendency of presence of foreign archaeologists in Portugal, under protocols established between different entities and respecting the necessary legal procedures. But we are also witnessing the inverse process, that is, the presence, even if limited in time, of young Portuguese in foreign archaeological institutions and excavations.

It is in this sense that we propose to identify, to know and to understand the influence exerted by this new generation that, returning from their short-term internships abroad where they establish new networks of personal and institutional contacts, influences, directly and indirectly, the course of archaeology in Portugal in the period under analysis.

5 **PRE- AND PROTOHISTORIC STUDIES IN THE DAWN OF NEW WAVES IN ARCHAEOLOGY – THE GERMAN ARCHAEOLOGICAL INSTITUTE IN MADRID 1954-1994**

**Abstract author(s):** Sasse-Kunst, Barbara (Albert-Ludwig-Universität Freiburg, Institut für Archäologische Wissenschaften)

**Abstract format:** Oral

The first part of this study about methodology and concepts of investigations of the German Archaeological Institute's department in Madrid dealt with the conceptions for this new institution in the time of its first foundation during the World War II under fascistic governments in Germany and Spain. It showed the intend to avoid investigations with political explosiveness in favour of mean explosive themes and methods, and a preference of humanism and art history in spite of empirical excavation archaeology. The second part of this study, concerning the period after the reopening of the institute in 1954 until the end of the "era Hermanfrid Schubart" in 1994, should widen the horizon in four directions: 1. to the new pre- and protohistoric section of the institute, beginning to work 1955 with empiric positivistic excavation methods, interdisciplinarity and historic-archaeological interpretation method and diffusionism; 2. to the involved German schools of Marburg and East Berlin; 3. to the interaction between Iberian and German investigators and if conceptions and methods were accepted, and 4. to the question of methodological change within this period, its nature and its periodization. To find answers I shall examine selected theoretical and practical works of the main investigators.

6 **‘SLAVIC ARCHAEOLOGY’ AND ITS IDEOLOGICAL AND POLITICAL INTERPENETRATIONS IN POLAND AND EAST GERMANY AFTER 1945. A COMPARATIVE-BIOGRAPHICAL CASE STUDY**

**Abstract author(s):** Kluger, Anne (Leibniz-Institute for the History and Culture of Eastern Europe - GWZO; University of Münster)

**Abstract format:** Oral

After 1945, the term 'Slavic archaeology' was used in the Eastern Bloc to describe the archaeological and historiographical research on the early 'Slavs' from prehistorical and early medieval times. Examining 'Slavic' roots, migrations, and material culture(s) as well as the origins of 'Slavic' statehood, which were traced back to the ancient past, represented one of the main branches of archaeology and prehistory within the Soviet sphere of influence.

This research focus, which at times received particular support by the communist rulers, was all the more remarkable in light of the fact that the underlying idea of 'Slavic archaeology', that a 'Slavic entity' had existed throughout history, technically contradicted the Marxist-Leninist world view (focusing on 'classes' as the relevant historical categories). Based on this observation, which seems contradictory only at first sight, I aim to discuss the role of 'Slavic archaeology' under these circumstances and its political and ideological interpenetrations. I therefore focus on communist Poland and East Germany, as I take two leading figures of Polish and East German 'Slavic archaeology' as case studies: Witold Hensel (PPR) and Joachim Herrmann (GDR), who headed the prehistorical institutes at the Academies of Sciences in their countries and were considered experts on the early 'Slavs' within the respective national and international scientific community. By analysing the archaeological interpretations and narratives, which Hensel und Herrmann presented in their scientific publications, I aim to draw conclusions about the archaeological and historical discourses of their time concerning the early 'Slavs' and their relation with the political and ideological environment. Furthermore, the comparative-biographical approach enables to identify transnational developments, networks, and interactions between communist Poland, East Germany, and other members of the Eastern Bloc as well as Polish and East German specifics.

7 **TRENDS IN THE DEVELOPMENT OF SOVIET RUSSIAN PROVINCIAL ARCHEOLOGY**

**Abstract author(s):** Shcherbakov, Nikolai - Shuteleva, lia - Leonova, Tatiana (Laboratory of Methodology and Methods of Humanitarian Research M.Akmullah Bashkir State Pedagogical University)

**Abstract format:** Oral

In 1960–1980 Soviet archaeology began its transformation from Marxism to Neo-Marxism. Archaeology in the USSR had a special aspect: development of theory, methodology and methods of research was determined by peculiarities of publication and keeping of manuscripts. The first direction is an official historical doctrine based on the formation approach to history. The development of archaeology in the USSR was similar to that of archaeology in Czechoslovakia as described by Eduard Krekovic and Martin Baca in 2013. Theoretical constructions of Soviet archaeologists of 1960–1980 were dedicated to the matter of archaeology and the nature of archaeological sources, structure of archaeological knowledge, the basic category of "archaeological culture", etc., but could not bring to life issues such as formation scheme and discussion on pre-capitalist modes of production and on "Non-Historic

Nations". Second, alternative direction of archaeologic theory in the Soviet Union was represented by doctrines of "samizdat". In 1980's quite often such works were created under the influence of "bourgeois" archaeologic theory. In 1980's "samizdat", a form of dissident activity, was represented by deposited manuscripts containing discussions of different approaches to the theory of archaeology. At the end of 1980's – beginning 1990's theoretical archaeology in the USSR experienced significant impact of western theoretical constructions. This impact manifested in correlations of ethnographic and archaeological sources. Weakening of Soviet ideology resulted in Russian scientists' moving off the principles of Marxism in archaeologic theory and in attempts to lean on Neo-Marxism. In the provincial archaeology of the USSR in the 1960's – 1980's national archaeology began to develop. The role of women archaeologists in the provinces has grown. M. Sadykova became the first Bashkir woman archaeologist. In difficult conditions, she investigated the sites of the early Iron Age and the Middle Ages.

8 **BETWEEN AMBITION AND REALITY – THE FEDERALIZATION PROCESS OF THE ARCHAEOLOGICAL SOCIETY OF YUGOSLAVIA (1959–1972)**

**Abstract author(s):** Lorber, Crtomir (University of Ljubljana)

**Abstract format:** Oral

European archaeological communities were forced to contend with the aftermath of WW2. An interesting example can be seen in Yugoslavia, where the war's aftermath led to the reorganization of the archaeological discipline, beginning with the 1st Consultation of the Yugoslav archaeologists in Niška Banja (1950) and followed by the formation of the Archaeological Society of Yugoslavia (ASY) (1953–1972). Its purpose was to lead a unified development of Yugoslav archaeology. A problematic concept since there never was a Yugoslav archaeology, rather there was a mix of national archaeologies that differed in organisation and development levels. This idea of a unified development of archaeology in Yugoslavia was soon replaced by an idea of federalization, embodied in a process of the transformation of the ASY, from a unified society towards an Association of Archaeological Societies of Yugoslavia (AASY) (1972–1991).

We will show the goals of the Archaeological Society of Yugoslavia, focusing on its' unifying ambition. We shall discuss why did ASY relatively quickly accept the concept of federalization – the formation of the ASY's Slovene section (1959) represents the beginning of this process – focusing on the 1963–1972 period, during which ASY was transformed into an association of equal national archaeological societies. We formulate a thesis society's reorganization was a consequence of self-critical realization by different Yugoslav archaeologists, who realized that their ambition of integrating different national archaeological traditions into a coherent whole was an unworkable project. Although this project was unrealistic, we can say it widened the horizons of national archaeologies in Yugoslavia and integrated them into the wider European environment. We conclude with an overview of the consequences of said federalization, as shown by the coexistence of the AASY with Slovene and Croat archaeological societies (1972–1991), emphasizing similarities, trends of continuity from the ASY and differences in their outlook.

9 **HURRYING UP SLAVS: INTRODUCTION OF SLAVIC ARCHAEOLOGY IN YUGOSLAVIA (1945 – 1960)**

**Abstract author(s):** Novakovic, Predrag (University of Ljubljana)

**Abstract format:** Oral

Except in Croatia, Slavic archaeology did not exist in other Yugoslav national/regional archaeologies before the WW II. This may be surprising since the development of 'national' archaeologies was already long ago closely connected with national movements and politics. While this was the case in Croatia where archaeology of Early Croats was institutionalized at the end of the 19th century, the archaeology in Slovenia, Serbia and Bosnia and Herzegovina did not follow the same steps. Besides other things, there were simply not enough local Slavic finds and sites in these lands to create more robust 'national' archaeological corpora. The situation radically and rapidly changed after 1945 when in the new, Communist-ruled Yugoslavia, Slavic archaeology became the top priority but had to be established literally from scratch, also to refute the 'imperialist and racist' interpretations of the German, Italian and Bulgarian archaeologies which were deeply engaged in changing the past of the Yugoslav nations.

The initial phase took some fifteen years in which the elementary conceptual apparatus, databases and major interpretative models were designed and canonized. All this was done by a handful of archaeologists of the new post-war generation manoeuvring between the then-dominant historical interpretations, Yugoslav Socialist-Marxist concept of brotherhood-and-unity, requirements for national emancipation of the Yugoslav nations, and archaeological standards of the time. By the early 1960s, the Yugoslav archaeologists started to participate at the Slavic archaeology international conferences in Europe gradually building up a respectable reputation. This process could not go without international cooperation in very challenging political circumstances in the early Cold War years. At first sight, the task was accomplished. Still, a deeper analysis reveals a series of shortcomings, 'shortcuts' and simplifications in this process, which started to be corrected only later, from the 1970s onwards; this process is still underway, but now, in new political circumstances.

**Theme:** 4. Globalisation and archaeology

**Organisers:** Rose, Helene (Centre for Baltic and Scandinavian Archaeology) - Christensen, Lisbeth (Department of Archaeology, Museum of Southern Jutland) - Møller, Niels (Museum Thy) - De Mulder, Guy (Department of Archaeology, Ghent University) - Louwen, Arjan (Faculty of Archaeology, Leiden University)

**Format:** Regular session

This session explores the current state of research into the North and West European urnfield phenomenon in the last millennium BC. The urnfields occur slightly later in the northern and western European coastal plains than in the central European core areas of the Urnfield Culture. The introduction of urnfields as large collective burial monuments was a very distinct cultural development, though across much of North and West Europe the urnfields were incorporated into the various local burial traditions.

The urnfields have traditionally played a major role in constructing the typo-chronological frameworks of the Late Bronze Age and Early Iron Age. In later years, the reinvestigation of urnfield materials shows the potential for in further in-depth studies of burial rites, artefacts and osteological material in the study of e.g. absolute chronology, cultural identity, networks of exchange, demography and cosmology. We invite papers that present the urnfield phenomenon in different regions, reviews of existing typo-chronological systems using relative or scientific dating methods and applications of scientific methods on urnfield material (e.g. strontium isotopes and radiocarbon dating). We especially welcome papers that ask new questions of existing urnfield collections or explore interconnectivity in Northern Europe in the last millennium BC as expressed through the urnfield burial practices.

This session is part of the network project 'URNFIELD - The urnfield phenomenon in Denmark and Northern Germany', funded by Interreg Deutschland-Danmark.

ABSTRACTS:

1 LATE BRONZE AGE URNFIELDS IN BELGIUM : A CROSSROADS OF FUNERARY TRADITIONS

**Abstract author(s):** De Mulder, Guy (Ghent University)

**Abstract format:** Oral

During the Bronze Age, present-day Belgium was oriented to two cultural areas: the Scheldt basin to the Atlantic complex and the Meuse basin towards Central-Europe. The funerary ritual of cremation, which is associated with the spread of the urnfields, was already present during the Early and Middle Bronze Age. From 1500 BC onwards, the first indications of isolated flatgraves and small urnfields appears already in the archaeological record, but they become only dominant from 1200 BC on. Diversity in these urnfields can vary from small cemeteries with a few cremation deposits to large urnfields with 100's of graves. Also the way in which the cremation remains are deposited can be very different. During the Late Bronze Age central-European influence becomes more pronounced during the phase Ha A2-Ha B1 (1100-900 BC) with the spread of the group Rhin-Suisse-France orientale (RSFO). The group RSFO is prominent visible in the southern part of Belgium, especially in the material culture. However, the dominant funerary practice in this region seems to be inhumation in caves. Group RSFO influence is also visible in the Scheldt basin but one a limited scale. One of these elements is the adaption of its ceramic repertory in the funeral practices. Next to the Atlantic and Continental cultural aspects, contact with northwestern Europe is visible in the funerary ceramics at certain urnfields which forms are related to the Westphalian region in Germany.

2 THE CEREMONIAL WAGON AND URNFIELD IDEOLOGY – AN EXPORT HIT?

**Abstract author(s):** Pankau, Claudia (Goethe-Universität Frankfurt, Abt. III Vor- und Frühgeschichte)

**Abstract format:** Oral

A rare but central element of the Urnfield Culture, closely linked to cremation and waterbird-sun iconography, is the horse-drawn ceremonial wagon. The oldest evidence of these complex "high-tech products" of their time, which can be dated in BzD, originates from the Carpathian Basin and southern Central Europe, while in the late Urnfield period the focus is clearly in the west of Europe. On the one hand, this phenomenon is due to the fact that most of the wagon fittings were found in hoards - and the rise of the hoarding practice in Late Bronze Age Europe can also be described as a time-shifted spread from southeast to northwest. On the other hand, it is probable that these wagons conveyed a central religious message, which had to do closely with the Urnfield Culture's new concept of the afterlife. Can the spread of ceremonial wagons to the north and west of Europe thus also be seen as a side effect of the obvious attractiveness of the "Urnfield ideology"? Did this ideology have a collective core, and was the ceremonial wagon used as ritual vehicle of an entire group, while its successor in the Hallstatt period can primarily be interpreted as status symbol of elitist individuals?

The aim of this contribution is to analyze the spread of the ceremonial wagon to the north and west of Europe in the course of the Late Bronze Age, either as real imported goods or as an idea, and to discuss the possible ideological reasons for this. Basis of the study are the bronze fittings that can be addressed more or less safely as parts of wagon and horse harness. The meaning of ceremonial wagons in the social and religious systems of their vast distribution area is considered in a differentiated way according to time and space.

3 BREAKING AND MAKING THE ANCESTORS

**Abstract author(s):** Louwen, Arjan (Leiden University, Faculty of Archaeology)

**Abstract format:** Oral

The Lower-Rhine-Basin is literally dotted with Late Bronze Age and Early Iron Age cremation grave cemeteries. In the Netherlands alone, more than 700 sites have been documented that produced cremation graves dating to these successive periods. Traditionally, these cemeteries are seen as the product of local adaptations of burial customs famous for the Central European 'Urnfield Phenomenon.' However, a recent study of the Dutch dataset suggests that funerary traditions in the Lower-Rhine-Basin developed much more autonomously over the course of the second millennium BC than was until recently thought. Not only do the funerary practices observed seem to tie into much older notions about ancestry and senses of belonging the land but the destructive and transformative qualities of the cremation process also provided the perfect means for emphasising these notions. Based on an extensive dataset of more than 3,000 cremation graves dating to the second and last millennium BC this paper will showcase how in the Lower-Rhine-Basin the dead were believed to relate to each other, how plain and simple objects could be used as metaphors in the creation of relational and ancestral identities and how the dead were inextricably linked to the land.

4 THE OCCURENCE OF THE URNFIELD-PHENOMENON AT THE CEMETERY OF MANG DE BARGEN, SCHLESWIG-HOLSTEIN (NORTHERN GERMANY)

**Abstract author(s):** Schaefer-Di Maida, Stefanie (Institute of Pre- and Protohistoric Archaeology, CAU Kiel; CRC 1266) - Kneisel, Jutta (Johanna Mestorf Academy Kiel)

**Abstract format:** Oral

At the Mang de Borgen site (Bornhöved, district Segeberg, federal state Schleswig-Holstein) we were able to find a burial ground with barrows, which were used in the Late Neolithic and the Older Bronze Age. Since the transition from Older to Younger Bronze Age (around 1300 BCE) the barrow areas were used for urns burials, which were interred in the immediate vicinity of the grave mounds. In the Iron Age, an extensive urn cemetery was built in the close proximity of the burial ground. With the help of extensive radiocarbon dating, which is available in this amount for the first time for a site in Schleswig-Holstein, it is possible to determine not only the enduring use beyond the various time periods, but also the different sequences of burial types (inhumation, cremation) and grave furnishings (grave goods, grave vessels, grave construction), which also seem to show a connection to the age of the occupants, as anthropological investigations made clear.

Furthermore, the dating was extended to other sites in Schleswig-Holstein. The data so obtained allowed us to come up with new explanations for the distribution of the cremation burial customs: for example, their distribution patterns appears to be independent from those of the urnfield phenomenon, at least in Schleswig-Holstein. This and other considerations regarding the distribution and influence of the urnfield phenomenon will be further discussed for the North of Germany.

5 DANISH IRON AGE URNFIELDS - A COMMUNITY OF ANCESTORS

**Abstract author(s):** Møller, Niels (Museum Thy)

**Abstract format:** Oral

This paper will present the results of an in-depth study of two Preroman Iron Age Urnfields in South-Western Jutland, Denmark as a starting point for a wider discussion of the late urnfield phenomenon in Western Denmark. The project applied the first major study of osteological materials from Danish urnfields revealing a large proportion of interred children and post-interment curation of bones from some graves, suggesting a prolonged interaction with the deceased. Urns show signs of ritual dismantling during burial. All burials adhere to strict regulatory principles of burial rites. Cremations are all done at approximately the same temperature, burial goods are kept at a minimum and all individual expression minimized. Size of urns and burial monuments on the other hand vary with the age of the individual suggesting that both urn and burial monument is an embodiment of the individual buried. The Danish urnfields, their monuments and the treatment of the deceased show similarities with urnfields from Northern Poland, Northern Germany and the Netherlands.

6 INVESTIGATING URNFIELD ARTEFACT ASSEMBLAGES WITHIN A BAYESIAN CHRONOLOGICAL FRAMEWORK

**Abstract author(s):** Rose, Helene (ZBSA - Centre for Baltic and Scandinavian Archaeology; CRC 1266 Scales of Transformation)

**Abstract format:** Oral

The chronological frameworks of the Pre-Roman Iron Age in Southern Scandinavia (c.500-200 BC) have traditionally been based on typo-chronological analysis of artefact assemblages from the large urnfield cemeteries located in Southern Jutland in Denmark. Carl Johan Becker's influential chronology from 1961 was primarily based on his excavations of Aarre urnfield, and more recently, both Aarre and Aarupgaard urnfields contributed significantly to Claus Kjeld Jensen's chronology from 2005. This paper presents a continuation of this urnfield research tradition with a re-investigation into the chronology of the urnfield tradition based on artefact assemblages from three urnfield cemeteries, Aarupgaard, Aarre and Søhale. The project presents the first large-scale 14C dataset in support of the chronological framework of the Pre-Roman Iron Age, in contrast to earlier work that has been largely unconstrained by scientific dating because the period coincides with a major plateau in the radiocarbon calibration curve (c.750-400 cal BC). Re-

cent methodological advancements now allow the cremated bone to be radiocarbon dated, thus offering an indirect date of the associated burial and artefacts. Having multiple dates on the same type of artefacts enables their currencies, i.e. the period a type was in production, to be modelled dynamically within a Bayesian chronological framework. There are demonstrated difficulties in correlating metalwork and pottery, which can be a challenge when comparing funerary and settlement evidence, but the artefact currency models provide an absolute correlation of metalwork and pottery as a mean to overcome this challenge. The currency models also provide new insight into the temporal processes of change in material culture by demonstrating periods of both rapid and slower change in the material culture. The chronological frameworks of the Pre-Roman Iron Age are evaluated based on the independent radiocarbon evidence and absolute estimations of key transformation points will be offered.

7 **LATE BRONZE AGE MOBILITY AND INTERACTION AT SIMRIS II (SCANIA, SOUTHERN SWEDEN)**  
**Abstract author(s):** Sabatini, Serena (University of Gothenburg) - Ladegaard-Pedersen, Pernille (National Museum of Denmark) - Kristiansen, Kristian (University of Gothenburg; Globe Institute, GeoGenetics Centre, Denmark) - Frei, Karin (National Museum of Denmark)

**Abstract format:** Oral

The Late Bronze Age urnfield phenomenon in southern Scandinavia, when seen as an attempt to create large collective burial monuments may play a significant role to widen our understanding of the social and cultural dynamics within local communities. An in-depth analysis of given contexts may unveil significant information not only about the single individuals buried in them, but about the whole community using the site. Northern European Late Bronze Age communities adopted different types of burial monuments that at times show strong similarities with practices common in other European regions. Each burial is likely to have been an event that groups of various sizes attended, following norms, rituals, and customs, or eventually also transforming them and/or introducing new ones.

In order to unveil possible patterns of mobility and interaction with the outside world in the community burying its dead at the Simris cemetery we have carried out strontium isotopes analyses on the six individuals whose bone remains were preserved well enough to allow such investigation. The number of samples is too limited to make statistics reliable. However, the results suggest that the complexity ‘at display’ in Late Bronze Age urn burials from Southern Scandinavia is far from being fully understood and invite to reassess the methodological approach when investigating mobility in communities practicing cremation.

412 **PEOPLE ON THE MOVE: CHANGING GENES, CULTURES AND LANGUAGES**  
**Theme:** 5. Assembling archaeological theory and the archaeological sciences  
**Organisers:** Torv, Mari (Department of Archaeology, Institute of History and Archaeology, Faculty of Arts and Humanities, University of Tartu) - Tambets, Kristiina (Institute of Genomics, Institute of Genomics, University of Tartu) - Vesakoski, Outi (Department of Finno-Ugric Languages, University of Turku) - Moilanen, Ulla (Department of Archaeology, University of Turku) - Kask, Silvia-Kristiin (Department of Archaeology, Institute of History and Archaeology, Faculty of Arts and Humanities, University of Tartu)

**Format:** Regular session

Population encounters - migrations, dispersal and admixtures - have brought about changes in cultures, languages, genes, and landscape through history. Recently, ancient DNA studies pointing to considerable temporal changes in the European gene pool have resurged migration as an explanatory model for cultural change in prehistoric societies. These scientific findings, however, have rarely been discussed in a more theoretical framework to demonstrate the complex relation between material and immaterial cultures, and genes. Instead, the biochemical and -molecular data produced under the umbrella of the 3rd Scientific Revolution in archaeology have been suited to old models in explaining cultural changes in the past. We have far less acknowledged the conceptual discussions from the beginning of the 21st on the matter of social identities (see Furholt 2019).

In this session we discuss the theoretical challenges in bringing together humanities and natural sciences. We invite case studies and wider theoretical contributions to discuss the interplay between archaeological/anthropological theories and archaeological sciences in the context of piles of data obtained with a variety of laboratory methods during the last decade. We welcome researchers combining archaeology, and linguistics with genetics and other biomolecular analysis, and archaeological/anthropological theories to study changes caused by (pre)historic population contacts. The presentations could focus either on i) the state-of-the-art methodologies in any of these fields or in interdisciplinary studies of human past, ii) challenges of bringing together archaeology, genetics, linguistics and other disciplines in the study of cultural change in (pre)historic societies and/or iii) to the challenges and threats in communicating the novel results to the wider non-academic audiences.

Furholt, M. 2019. Re-integrating Archaeology: A Contribution to aDNA Studies and the Migration Discourse on the 3rd Millennium BC in Europe Proceedings of the Prehistoric Society 85, 2019, pp. 115–129.

ABSTRACTS:

1 **GENETIC ANCESTRY CHANGES IN STONE TO BRONZE AGE TRANSITION IN THE EAST EUROPEAN PLAIN**  
**Abstract author(s):** Saag, Lehti (University of Tartu) - Vasilyev, Sergey (Russian Academy of Sciences) - D’Atanasio, Eugenia (Italian National Research Council) - Kivisild, Toomas (University of Tartu; KU Leuven) - Scheib, Christiana Lyn (University of Tartu; University of Cambridge) - Tambets, Kristiina - Kriiska, Aivar - Metspalu, Mait (University of Tartu)

**Abstract format:** Oral

The transition from the Stone to the Bronze Age in Central and Western Europe was a period of major population movements originating from the Ponto-Caspian Steppe. Here, we report new genome-wide sequence data from 30 individuals from the territory north of this area – from the under-studied Western part of present-day Russia.

We present genetic data from three Stone Age hunter-gatherers (10,800–4,250 cal BCE), including an on average 5x covered shotgun sequenced genome. Furthermore, we have sequenced the genomes of 26 Bronze Age farmers associated with the Fatyanovo Culture (2,900–2,050 cal BCE). Fatyanovo Culture is the easternmost extension of the Corded Ware cultural complex that was spread over a large area in Western Russia and introduced animal husbandry and probably crop cultivation into the forest belt.

We show that Eastern hunter-gatherer ancestry was present in Northwestern Russia already from around 10,000 BCE. Hence, we present the highest coverage whole genome and oldest individual with this ancestry published so far. Furthermore, we see a change in ancestry with the arrival of farming – Fatyanovo Culture individuals were genetically similar to other Corded Ware cultures, carrying a mixture of Steppe and European early farmer ancestry. We propose that the possible origin of the migration leading to the formation of the Fatyanovo Culture and of the Corded Ware cultures in general could be modern-day Ukraine, which is the closest area where these ancestries coexisted from around 3,000 BCE.

2 **THE ORIGIN AND GENOMIC LEGACY OF THE ETRUSCANS**  
**Abstract author(s):** Posth, Cosimo (Archaeo- and Palaeogenetics group, Institute for Archaeological Sciences, University of Tübingen; Achaeogenetics Department, Max Planck Institute for the Science of Human History, Jena) - Zaro, Valentina (Department of Biology, University of Florence) - Spyrou, Maria (Archaeo- and Palaeogenetics group, Institute for Archaeological Sciences, University of Tübingen; Achaeogenetics Department, Max Planck Institute for the Science of Human History, Jena) - Vai, Stefania (Department of Biology, University of Florence) - Gneccchi-Ruscone, Guido (Achaeogenetics Department, Max Planck Institute for the Science of Human History, Jena) - McCormick, Michael (Initiative for the Science of the Human Past, Department of History, Harvard University) - Bondioli, Luca (Bioarchaeology Service, Museum of Civilizations, Rome) - Bos, Kirsten (Achaeogenetics Department, Max Planck Institute for the Science of Human History, Jena) - Caramelli, David (Department of Biology, University of Florence, Italy) - Krause, Johannes (Achaeogenetics Department, Max Planck Institute for the Science of Human History, Jena)

**Abstract format:** Oral

The Etruscan civilization occupied a large area of central Italy known as Etruria during the Iron Age. The history and legacy of this population remain enigmatic as well as its extinct language, a non-Indo-European language not fully interpreted until today. Two main competing hypotheses have been proposed for the origins of the population associated with the Etruscan civilization: an autochthonous development or an Anatolian birthplace. Here we report an ancient genomic time transect across Etruria alongside a historical and linguistic synthesis of our findings through time. During the Iron Age, we identify a mismatch between ancestry composition and the non-Indo-European Etruscan language challenging previous hypotheses on the recent Anatolian origin. The documented genetic make-up is stably maintained in Etruria across the first millennium BCE, despite the arrival of migrants as shown by the presence of several genetic outliers. However, this broad genetic continuity is overturned during the Roman Imperial period due to a large-scale spread in the region of eastern Mediterranean ancestries. This suggests that the Roman Empire might have left a long-lasting demographic contribution to the genetic profile of central Italian populations resulting in a vast displacement of the Etruscan-related gene pool.

3 **CONNECTIONS IN LATE IRON AGE BALEARIC COMMUNITIES: THE CASE STUDY OF THE STAGGERED TURRIFORM OF SON FERRER**  
**Abstract author(s):** Salvador, Paloma - Calvo, Manuel (University of the Balearic Islands) - Santos, Cristina (Autonomous University of Barcelona) - García, Jaume (University of the Balearic Islands)

**Abstract format:** Oral

In the last decades, ancient DNA studies have proven to be a very powerful tool for studying mobility and kinship in prehistoric communities. Thus, we aim to present a case study of a Balearic archaeological site that uses Palaeogenetics to better understand Late Iron Age Balearic communities.

The Staggered Turriform of Son Ferrer is a Postalaitic (Late Iron Age) archaeological site (650/550-123 BC) located in the Calvià peninsula in southwestern Majorca (Balearic Islands). During the Postalaitic period, this site worked as a necropolis. As a result of the study of the ceramic materials recovered there, we hypothesized that the individuals buried there came from different archaeological sites in this area.

This necropolis remained as a closed context until the time of its excavation. Hence, it is an ideal place to carry out an anthropological study at both osteological and molecular levels. This study is also allowing us to delve into the study of communities from Postlalaotic period, a time of great social, economic, and ideological changes. Furthermore, it is a moment in which the presence of the Punic (settled in Ibiza since the 6th century BC) in the Mediterranean Sea becomes stronger.

Through this project we aim to: i) examine the patterns of mobility and isolation, ii) analyse what insularity implies at a genetic level, iii) explore the regional connectivity of the prehistoric communities of this moment, iv) assess the intensity of the contact between the indigenous people and the Punic communities and v) contrast the hypothesis that the Staggered Turriform of Son Ferrer worked as a meeting place.

We intend to present the first results of the osteological analysis of this archaeological site and how we will address future aDNA analysis. We will also approach the state of the art of Palaeogenetic studies in the context of Balearic prehistory.

#### 4 MIGRATION PERIOD ELITES FROM LITHUANIA – LOCALS OR MIGRANTS? NEW INSIGHTS BASED ON ARCHAEOLOGICAL AND NATURAL SCIENCES DATA

**Abstract author(s):** Kurila, Laurynas - Simčėnka, Edvardas (Lithuanian Institute of History; Vilnius University) - Piličiauskienė, Giedrė - Miliauskienė, Žydrūnė (Vilnius University) - Lidén, Kerstin (Stockholm University)

**Abstract format:** Oral

In the Migration period, Europe saw a turbulent era of movement of nomads and Germanic peoples, rise and collapse of the Hunnic Empire and fall of the West Rome, and complete reshape of the social landscape. Hypotheses are suggested that these events also touched the then remote periphery of the Barbaricum in the present-day Lithuania, i.e. that warrior or marauder bands from the Carpathian basin, Central Europe, or Black sea coasts reached the region, or that Balt warriors returned home after distant military campaigns. These people are related to new elites: males buried with prestigious non-local ornaments, weapons, and horses of exceptional body size, and females buried with rich non-local adornments. Hypotheses of savage invasions and immigration of elite dominate Lithuanian archaeological narratives, which, however, lack solid empirical background.

The results of <sup>87</sup>Sr/<sup>86</sup>Sr and <sup>180</sup>/<sup>160</sup> stable isotopes analysis and AMS dating of Migration Period humans (both the elites and commoners) and horses from Lithuania will be presented, as well as isotopic measurements of faunal remains serving as local baselines. The results demonstrate that most of the individuals are of local origin, except of only several humans and horses with a higher degree of mobility. New insights will be proposed: first, individuals of possible non-local origin are those from the elite group, second, this applies to both males and females, and third, different regions of provenance can be hypothesized for individuals from different parts of Lithuania.

However, interpretation of the isotopic results and combining these results with archaeological data appeared more complicated than expected. Several “migrants” were not representatives of local communities, but their place of origin may be either a nearby settlement or the provinces of the Roman Empire. In our presentation, we will discuss the challenges we met bringing together archaeology and natural sciences, and perspectives in this field.

#### 5 MIGRATION AND ADMIXTURE EVENTS ON THE EURASIAN STEPPE AND THEIR IMPACT ON THE EARLY MEDIEVAL POPULATIONS OF THE VOLGA-URAL REGIONS

**Abstract author(s):** Gyuris, Balázs - Szeifert, Bea (Institute of Archaeogenomics, Research Centre for the Humanities, Eötvös Loránd Research Network; Department of Genetics, ELTE-Eötvös Loránd University, Budapest) - Ringbauer, Harald (Department of Archeogenetics, MPI for Evolutionary Anthropology, Leipzig) - Türk, Attila (Faculty of Humanities and Social Sciences, Institute of Archeology, Pázmány Péter Catholic University) - Mende, Balázs (Institute of Archaeogenomics, Research Centre for the Humanities, Eötvös Loránd Research Network) - Reich, David (Department of Genetics, Harvard Medical School; Department of Human Evolutionary Biology, Harvard University) - Szécsényi-Nagy, Anna (Institute of Archaeogenomics, Research Centre for the Humanities, Eötvös Loránd Research Network)

**Abstract format:** Oral

Ancient Hungarians are considered to originate from the Ural region of Russia. During their westward spread they reached the Middle-Volga and Kama regions, and later the Dnieper and Dniester regions from where in the late 9th century AD, they settled in the Carpathian basin. The location of the ancient homeland of the Hungarians is debated, although archaeological and fresh genetic evidence show parallelism between Hungarian conquerors in the Carpathian basin and the population of the southern Trans-Ural region, associated with the Kushnarenkovo and Karayakupovo cultures (6-10th century AD). These uniparental results suggest that people of the Kushnarenkovo culture may have taken part of the formation of the later Hungarian conquerors or have a common genetic source. Here we focus on the main migration events that shaped the Western Siberian-Ural region in the Late-Iron Age and the Western-Eurasian steppe from the Migration Period to the early Medieval Era. In our whole genome analysis we use enrichment for 1.24 million single nucleotide polymorphisms (SNPs). Understanding the distribution of the ancestry proportions in this wide area should help us to detect possible source populations of the Kushnarenkovo and subsequent cultures of the Volga-Ural region and the later Hungarian conquerors in the Carpathian Basin. Moreover, modeling population transformations in the Ural region has the potential to answer fundamental but highly debated questions about the origins not only of proto-Hungarians and later conqueror Hungarians but also closely related populations. In this talk, we will discuss admixture events leading to the formation of these populations, discuss the extent of genetic continuity, and provide insight into the dynamics of complex migration patterns. We will also

discuss the challenges of joining and presenting scientific evidence from archaeological, historic and genetic results on a politically charged topic.

#### A. ANCIENT DNA ANALYSIS OF EARLY MEDIEVAL ALAN POPULATIONS OF THE NORTH CAUCASUS

**Abstract author(s):** Dzhaubermezov, Murat (Institute of Biochemistry and Genetics - Subdivision of the Ufa Federal Research Centre of the Russian Academy of Sciences, Ufa; Department of Genetics and Fundamental Medicine, Bashkir State University, Ufa) - Gabidullina, Liliia (Department of Genetics and Fundamental Medicine, Bashkir State University, Ufa) - Ekomasova, Natalia - Khusnutdinova, Elza (Institute of Biochemistry and Genetics - Subdivision of the Ufa Federal Research Centre of the Russian Academy of Sciences, Ufa; Department of Genetics and Fundamental Medicine, Bashkir State University, Ufa) - Atabiev, Biyaslan (Ltd. Institute for Caucasus Archaeology) - Chagarov, Ongar (Laboratory of Contextual Anthropology at the Institute of Archaeology of the Russian Academy of Sciences) - Aybazon, Akhmat (Director of the Archaeological Museum of the Umar Aliev Karachay-Cherkess State University) - Metspalu, Mait - Villems, Richard - Tambets, Kristiina (Estonian Biocentre, Institute of Genomics, University of Tartu)

**Abstract format:** Poster

The earliest existing written evidence about Alans – people of Ponto-Caspian steppes and Caucasus region of I-XIII century AD – is found in the works of Chinese authors who mention the politonym “Yancai” in the “Records of the Grand Historian” and in the “History of the Former Han”, and of European antique authors in the middle of the 1st century AD.

Genetic data of the early Middle Ages Alans and their affinities to the Scythian-Sarmatian tribes, traditionally considered as their ancestors, as well as to the modern population of Europe and the Caucasus have not yet studied thoroughly, the whole genome data exists for only 6 individuals [1].

In this study we have analyzed ancient DNA of 70 individuals from 12 burial complexes belonging to the Alan culture from the III-XIII century AD, from the territory of the North Caucasus (Russian Federation). DNA was extracted from the archaeological material (teeth, temporal bone) of 70 individuals. We produced low-coverage Illumina whole-genome shotgun sequencing data for 63 individuals and will analyze these in a context of ancient and modern genetic variation of the region. The coverage of the genomes was 0.0004-0.3X (median coverage 0.045X and content of endogenous DNA 21,45%). The preliminary analysis allows us to assume close contacts of the Alans with the populations of the North Caucasus. The Y-chromosomal palette of Alans consisting of 5 different haplogroups (R, Q, J, G, I) started to be similar to that of present day autochthonous North Caucasus populations only in the later phase of Alan culture.

This study is supported by the Ministry of Science and Higher Education of the Russian Federation (grant № FZWU-2020-0027), the Russian Foundation of Basic Researches (№ 19-04-01195 and №20-29-01018) and by the EU through the European Regional Development Fund (№ 2014-2020.4.01.16-0125).

#### 415 NORTHERN EURASIA IN THE LATE PLEISTOCENE-HOLOCENE: PERIPHERY OR TRANSIT ZONE? (PAMJ)

**Theme:** 6. Material culture studies and societies

**Organisers:** Ponkratova, Irina (North-Eastern state University, Magadan) - Lbova, Liudmila (St. Petersburg Polytechnic University) - Davis, Loren G. (Oregon State University)

**Format:** Session with precirculated papers

Modern research in the field of stone age archaeology shows that the Northern territories of Eurasia began to be actively developed by humans during the upper Paleolithic (MIS3-MIS2). For a long time, there was little interest in the development of the peoples of the North, their ethnogenesis and cultural, low visibility of archaeological materials, and the limited set of research topics compared to tropical or Mediterranean territories. Material practice of northern populations, the agency of things and the social interpretation of the impact of material culture are increasingly defining the contours of social archaeology.

Paleogenetic studies confirm the distribution of populations from Scandinavia to Alaska as wave - like process in Northern latitudes. Numerous archaeological and ethnographic collections obtained in recent years, have presented the cultural mosaic of the North. These have become available due to the unique special taphonomic conditions of burials of ancient hunters and fishermen. The stable preservation of this autochthonous population and traditional way of life allows us to employ ethnographic materials as correct analogies.

The section will consider the following issues:

- features of geological processes and taphonomy of cultural remains.
- variability of late Pleistocene and Holocene archaeological cultures.
- cultural traditions and innovations of societies of hunters, fishermen, and gatherers of the North.
- specifics and forms of adaptation strategies to low-temperature conditions.
- methods and means of transportation in the conditions of northern latitudes in the Prehistory.

ABSTRACTS:

1      **DISPERSAL OF THE LAMINAR INITIAL - EARLY UPPER PALEOLITHIC TECHNOLOGY: DEFINING OF NORTHERN BOUNDARY**

**Abstract author(s):** Rybin, Evgeny - Khatsenovich, Arina (Institute of Archaeology and Ethnography SB RAS)

**Abstract format:** Oral

The territory of the mountain belt in the Southern Siberia and Central Asia, ranging from 53 to 40 degrees north latitude, is the main region where distinctive MIS-3 laminar industries of early stages of Upper Paleolithic have been spread.

In the high latitudes of northern Eurasia, there are of several blade assemblages - Kolpakov Ruchey on the Northern Angara river, Makarovo-4 in the upper reaches of Lena river, Ust'-Chirkuo in Viliuy valley in Yakutia and Ust'-Maltat-2 and Derbina-4 sites on the Middle Yenisei. All these sites, located within 55-63 degrees of north latitude in the valleys of giant Siberian rivers still insufficiently studied, and situated in disturbed stratigraphic conditions. The technological and typological features of these assemblages indicate that they belong to the Initial Upper Paleolithic laminar industries entity. The distribution of these industries in high latitudes demonstrates the adaptation plasticity and marks the northern limits to the dispersal of Initial Upper Paleolithic populations.

This study was supported by the Russian Science Foundation grant No. 19-18-00198.

2      **WITH NO ANALOGUES: IUP ENGRAVED BEADS OF BELEMNITE ROSTRA**

**Abstract author(s):** Stepanova, Ksenia (Institute for the History of Material Culture, Russian Academy of Sciences; Saint-Petersburg State University, Institute of History, Archaeological Department) - Giryа, Evgeny - Bessudnov, Alexander (Institute for the History of Material Culture, Russian Academy of Sciences)

**Abstract format:** Oral

Assemblage of Kostenki 17, layer II (41 ka cal BP) is an eponymous and seems to be a single site for the "Spitsynian" – an Initial Upper Palaeolithic local taxon in the Middle Don basin which is characterized by the predominance of different types of burins, including special "Spitsynian" one. Kostenki 17, layer II is an important point to trace the paths of the initial settlement of Eastern Europe by anatomically modern humans. Assemblage includes quite unique personal ornaments made from perforated fossils, small pebbles and polar fox canines, among which 4 pendants from belemnite rostra have gained special attention in publications since the 1950s, but some questions of processing techniques remain unresolved. And the most controversial - how was the ribbed translucent surface obtained? For the IUP and EUP it is common to use personal ornamentation in the form of natural materials (tooth, shells etc.) with rare additional treatment as simple linear ornaments. In the case of Kostenki 17, layer II rostra were not only perforated by double-sided drilling, but also symmetrically engraved with a very sharp edge and specially mechanically and chemically treated, as we suppose according to micro traces on the rostra surfaces. Also, pendants were worn for quite a long time, and they were not broken before deposition in the cultural layer. As can be concluded, in this case we see a unique example of the prehistoric jewelry art, which does not yet have an analogue of comparable age, not only in the shape of pendants, but also in a wider range of technical methods of shaping and decorating the surface.

This work was funded by RSF grant №20-78-10151.

3      **TECHNOLOGICAL CHARACTERIZATION OF LATE PLEISTOCENE-AGED STEMMED PROJECTILE POINTS FROM THE USHKI LAKE SITE, LAYER VII, KAMCHATKA, RUSSIA**

**Abstract author(s):** Ponkratova, Irina (North Eastern State University) - Devis, Loren (Oregon State University, Department of Anthropology)

**Abstract format:** Oral

We provide the first 2D and 3D digital characterizations of stemmed projectile point technologies from the late Pleistocene-aged Layer VII at the Ushki Lake Site, located in Kamchatka, Russia. Our focus on the site's earliest cultural component is intended to more fully explore cultural elements of technological design, manufacture, and use reflected in the morphometric form of projectile weaponry. These characterizations are derived from photographs and photogrammetric models that are processed through the Geographic Information Systems Lithic Morphometric Research (GLiMR) approach to geometric morphometric measurement. This approach harnesses the analytical abilities of geographic information systems (GIS) software in order to render quantitative measurements of stone tools in ways that far exceed traditional manual techniques. Moreover, since these measures are derived from digital 3D models of artifacts, the results are highly detailed and replicable by other researchers who are provided virtual access to the Ushki collection items. This approach not only leverages the empirical power of GIS but represents a new approach to sharing archaeological information. Based on the results of the GLiMR measures, we seek to establish patterns of traditional technological practice shared among the late Pleistocene peoples who lived at the Ushki Lake site. We consider how these cultural patterns relate to other early projectile point technologies discovered in North America and what they may tell us about the initial lithic technological patterns employed by the First Americans. We hope that this study demonstrates an approach to the study of artifact collections that promotes an increase in international collaboration and fosters greater insight into the Pleistocene record of the northern Pacific Rim.

4      **SURVIVING TURBULENT TIMES: CLIMATE CHANGE, CULTURAL CONNECTIONS AND SHIFTING ADAPTATIONS IN HOKKAIDO-SAKHALIN DURING THE PLEISTOCENE-HOLOCENE TRANSITION**

**Abstract author(s):** Jordan, Peter (Department of Archaeology and Ancient History, Lund University; GSI, Hokkaido University) - Vasilevski, Alexander (World and Russian History, Sakhalin State University) - Kato, Hirofumi (GSI, Hokkaido University) - Grishchenko, Vyacheslav (Archaeological Museum, Sakhalin State University)

**Abstract format:** Oral

The Pleistocene-Holocene transition brought turbulent times to human societies confronted by rapid climatic fluctuations, shifts in biogeographic zones and the flooding of continental shelves. While the disappearance of Doggerland's inhabited landscapes under the grey waters of the North Sea marks the culmination of these changes for European Archaeologists, our aim is this paper is to draw parallels with Northeast Asia, where the islands of Hokkaido and Sakhalin once formed a major terrestrial extension of the vast Eurasian landmass. During the LGM, this terrestrial corridor offered an "escape route" from the harsh glacial conditions of Siberia, but as temperatures gradually warmed, prehistoric societies faced a growing subsistence crisis as landscapes flooded and faunal resources declined. Our goal is to understand how these societies responded to a warming – yet frequently unstable – climate in an ever-shrinking terrestrial world. Late Glacial warming witnessed to a brief expansion of Incipient Jōmon traditions into Hokkaido, cut short by the Younger Dryas. As Holocene warming accelerated, a broader suite of innovations including house pits, plant use and pottery expanded across Sakhalin and Hokkaido. The onset of the 8.2 cal. BP cold event partly reversed this trend, and brought Siberian lithic traditions (Blade Arrow Culture) back down through Sakhalin and into Hokkaido, signalling the temporary return to more mobile sub-arctic lifeways and a growing reliance on coastal resources. Understanding human- and community-scale responses to these major shifts is challenging because the region's acidic soils mean that bone material is not preserved, other than at a few shell-midden sites in Hokkaido. At the same time, the region's extended hunter-gatherer pottery traditions offer rich scope for undertaking biomolecular reconstruction of changing cooking practices across major cultural and environmental transitions. We report recent results, examine remaining gaps in knowledge, and present ideas for future research.

5      **FROM CONTINENT TO CONTINENT: PROPOSED PATHWAYS OF HUMAN TRAVEL FROM KAMCHATKA TO AMERICA IN ANCIENT TIMES**

**Abstract author(s):** Ponkratova, Irina (North Eastern State University)

**Abstract format:** Oral

The processes of both internal and external human migrations took place on the Kamchatka Peninsula during the Pleistocene – Holocene transition. This appears to have resulted in the replacement of existing populations during this time. The causes of human population displacement during this time period appear to be linked to general processes of environmental instability associated with catastrophic volcanic eruptions resulting in linked alterations of landscape, hydro-networks, floods, fires, earthquakes, tsunamis. These catastrophic volcanic eruptions may have resulted in the displacement of existing populations and migrations to safer regions. This may have resulted in the abandonment of interior regions and the occupation of coastal areas. This would have resulted in the passage of people along the northern coast of the Asian continent, along the coast of Beringia and ultimately to the west coast of America. Under these conditions the technological means of individual mobility would have played an important role to permit expeditious movement along rivers, across coastal waters and circumvent sea ice played an important role for the migration of human populations. Included among such technological innovations may have been the construction of seaworthy boats and dog sledges. It is critical that we develop testable hypotheses that permit the reconstruction of possible means of transportation to convey people across Asian to the American continent. An examination of existing archaeological collections and ethnographic descriptions of the peoples of Kamchatka and America can serve to inform the development of testable hypotheses.

6      **FINAL PALAEOLITHIC OSSEOUS TECHNOLOGIES IN THE EASTERN BALTIC: OVERVIEW OF DATA AND TAXONOMY ISSUES**

**Abstract author(s):** Rimkus, Tomas (Centre for Baltic and Scandinavian Archaeology - ZBSA)

**Abstract format:** Oral

The chronology and cultural periodization of the Final Palaeolithic in the Eastern Baltic was entirely formed on the basis of traditional typological-technological methods, studying lithic tools, tanged points in particular. In this way, by comparing the archaeological material with the analogous data of the adjacent regions, a chronological and cultural periodization of this period was formed, covering the period between the end of Bølling and early Preboreal. The vast majority of the studied sandy type settlements do not contain AMS dates, nor any dated organics and prehistoric tools made from them. Recent research intensification on stray prehistoric bone and antler artefacts in the Eastern Baltic has revealed the Final Palaeolithic working and hunting implements here, as well as early mobile art scenes on their surface. Current data show that the Final Palaeolithic communities in this region produced and used bone and antler products within a chronology of ca. 11 500 – 9 200 cal BC. On the basis of these researches, it became possible to a more precise chronology of the Final Palaeolithic, to typologize specific technologies and to observe technological development and transformations of such artefacts. Unfortunately, data on the cultural attribution of these tools are still lacking. However, by examining their chronology and linking them to the typological-technological aspects of the available lithic material, it became possible to link some groups of these implements to separate taxonomic units.

PALEOART OF NORTHERN EURASIA IN EARLY UPPER PALEOLITHIC: MATERIALS, TECHNIQUE, IMAGES, SEMANTICS

**Abstract author(s):** Lbova, Liudmila (Peter the Great St. Petersburg Polytechnic University; Novosibirsk State University)

**Abstract format:** Oral

The Initial and Early Upper Paleolithic in Siberia is represented by a mosaic combination of stone reduction technologies, bone and antler processing, as well as an amazing variety of anthropological fossil finds representing various species within of the Homo. Forms of symbolic behavior appear to be rather stable in the archaeological context of the Early Upper Paleolithic of northern Eurasia between 40,000-50,000 years ago. In the Middle to Upper Paleolithic transition in southern Siberia, surviving Middle Paleolithic technology forms converge with the appearance and evolution of Aurignacian elements. Here we use microscopic, technological, use-wear, and spectral analyzes to explore the manufacture and meaning of personal ornaments during these periods.

Based on studies of various Early Upper Paleolithic objects, a preliminary classification is proposed, presented in the form of a typological scheme of features incorporating forms and techniques for manufacturing items of personal adornment. In addition, to standard archaic forms (pebbles, bones, teeth, and drilled shells) we push new types such as “C-image” or “horned pendant”, figurative (geometric) forms and figurines with decoration and painting.

The system of joint meanings ensures the effectiveness and success of communication in human culture. Items of personal ornamentation can be defined as the material form of symbolic communication, endowed with qualitative characteristics of personal and cultural identity and expressed through a system of signs. It is possible that such items could play the role of exchange equivalents or prestige items. Based on the presence of exotic raw materials, teeth of unusual animals, or ostrich eggshell and seashell in the collections some items may be imported.

This work is supported by the Russian Science Foundation (project 18-78-10079).

VISIBLE TO THE EYE? TRANSMISSION OF IDEAS THROUGH EVERYDAY VISUAL CULTURE

**Theme:** 6. Material culture studies and societies

**Organisers:** Kurisoo, Tuuli (Tallinn University) - Sirkin, Annika (Centre for Baltic and Scandinavian Archaeology - ZBSA)

**Format:** Regular session

The material and the visual are combined in the archaeological record. Design and style of artefacts, but also different technological choices (e.g. materials, tools, and methods) participate actively in the production, reproduction and transformation of sociocultural meanings and values. These aspects become more pronounced when we consider long-term trends and developments.

The study of visual culture is closely related to the study of art objects and images, but we seek to expand the discussion on portable material culture that is not necessarily perceived as ‘art’. Decorated everyday items, dress accessories, and weapons can be named as examples of such objects. These items were often locally produced and can be seen as indicators of everyday visual culture. We would like to discuss the changes in the social, cultural and religious environments that affect design, style and iconography of portable material culture. We are interested in the dynamics of transformation, whether the changes took place gradually or rather abruptly and what was the scale of the changes in the visual culture (e.g. restricted to certain artefact types or used as a cross-reference between different artefact categories).

We welcome contributions that examine these topics and we would be particularly interested in papers that focus on a long-term perspective. This view helps to see a bigger picture, which is necessary for more balanced narratives about specific ideas (e.g. the spread of Christianity). The aim of this session is to bring together a wide range of case studies across all periods and places in Europe that enables insights into how the concept of visual culture can be expanded and explored in archaeology.

ABSTRACTS:

1

INTRODUCTION: EVERYDAY VISUAL CULTURE

**Abstract author(s):** Kurisoo, Tuuli (Tallinn University)

**Abstract format:** Oral

This paper introduces the general topic of visual culture with the focus on everyday material culture from Estonia. The movement of ideas, styles and designs are examined in a long-term perspective with the aim to understand the change in the visual culture that was stimulated by the spread of Christianity. The latter is still one of the most debated topic in Estonian prehistory, but visual culture has received only a little attention in the archaeological context. Moreover, most of the studies tend to focus on a single theme (mainly cross symbolism) or a specific time period around the Baltic Crusades in the beginning of the 13th century. It will be demonstrated that widening not only the temporal scale but also material base by including everyday items then new insights can be obtained how we tackle this problem. Therefore, visual culture is seen as a useful tool for revisiting old debates and introducing new lines of inquiries.

2

TIMELESS DESIGN - BIRD SHAPE LADLES FROM THE STONE AGE TO SOUVENIR SHOPS

**Abstract author(s):** Iršenas, Marius (Vilnius Academy of Arts)

**Abstract format:** Oral

The bird motif is one of the most important in the Stone Age in the Baltic region. A wooden ladle with a bird-shaped handle is reminiscent of a stylized water bird sculpture. Perhaps because of the suitability of this function and shape for depicting a bird, the tradition of such ladles does not end with the Stone Age. They are found in the archeological layers of medieval cities in the Baltic Sea region, in the jewellery collections of rulers, in the collections of 19th-20th centuries ethnography in museums, and in the souvenir shops of today.

What supports the longevity of such a design solution? The simplicity of the form and its constant rediscovery? The importance of the image of the bird in the worldview or other reasons that are difficult to see?

We will try to answer these questions in a presentation dedicated to the ever-young design of bird-shaped ladles.

3

MIGRATION PERIOD PICTURE STONES FROM GOTLAND – COMPARISONS TO OTHER STONE MONUMENTS AND METALWORK

**Abstract author(s):** Strehlau, Hannah (Centre for Baltic and Scandinavian Archaeology - ZBSA)

**Abstract format:** Oral

The Gotlandic picture stones are a unique find group that is limited to the Swedish island of Gotland. The carved stone slabs occur in various sizes and forms between 400 and 1000 CE. The Swedish researcher Sune Lindqvist divided the monuments in five different groups, A to E. The oldest group is, thus, group A (400-600 CE) and is central to this PhD project.

The so-called A-stones appear in trapezoidal or axe-shaped form and show a rather abstract ornamentation of geometric motifs, in combination with anthropomorphic and zoomorphic figures and border decorations. The sudden appearance in perfectly elaborated form and without previous development phase gives reason to explore their parallels and possible predecessors in Scandinavia and the Roman provinces. A possible connection exists to Roman Imperial tombstones from remote Spain and Portugal where both the choice of motifs and their arrangement on the stone resemble the Gotlandic monuments. Likewise, parallels exist to portable objects, such as Late Roman chip-carved metalwork, and artefacts decorated in the Nydam- and the Sösdala style. The task of this PhD project is, therefore, to collect material that is similar to the Gotlandic A-stones regarding style and motif. It aims to understand processes of idea transfers and to shed light on the long unanswered research question of the origins of these monumental stones.

4

TO SEE AND BE SEEN: ADOPTION OF ROMAN VISUAL CULTURE INTO FEMALE RELIGIOSITY OF DALMATIA

**Abstract author(s):** Mech, Anna (University of Warsaw)

**Abstract format:** Oral

Female religiosity in Roman Dalmatia represents a most interesting case study, as it is the province with the highest proportion of finds related to public cult activity of women among all the provinces of the Empire. This may be related to pre-Roman local customs and peculiarities of social organisation (Liburnia, the northern part of the province, was even described as “ruled by women” – which is a classic literary topos, but may be in some part based on reality) which gave women more religious agency than in other provinces. It is however precisely the adoption of Roman ways of visual and material expression of piety which allowed those women to produce the most permanent and visible manifestations of their religious activities. Votive monuments set up by women in this province follow mostly foreign, Roman patterns in their form and iconography, in their cultic purpose, in the customs associated with their erection, and in their public, social importance; as well as in the use of Latin as the language of religious communication. This is true even when the dedicants bear Illyrian, Celtic or other local names and use those objects to address local gods, pointing to an emergence of hybrid provincial religion. The paper will discuss not only the ways in which the inclusion of elements of Roman visual culture allowed the expression of female religiosity within the context of a provincial religion, but also the strategies used by Dalmatian women to visually mark their agency and complex cultural identities.

5

VISUALISING IDEOLOGIES: MANIFESTATIONS OF MODERNITY AND CONSERVATISM IN BRITISH PERIOD CYPRIOT DRESS

**Abstract author(s):** Hadjittofi, Petroula (University of Cyprus)

**Abstract format:** Oral

The post-Medieval history of Cyprus is defined by its successive subjugation to the Ottomans (1571-1878) and the British (1878-1960). The island’s integration in two expansive and diverse empires of the Early Modern and Modern world influenced in a decisive manner the quotidian life of its people. In the last decades of the Ottoman period (ca. 1830 onwards), and especially during the British period, Cyprus underwent a series of complex political, economic, social and cultural transformations, which led to modernisation and laid the foundations for the development of the contemporary Cypriot society and identity. Yet, despite their significance, these processes are not yet adequately studied, nor cohesively explored. Given the potential of a material culture approach to the analysis of social phenomena, this study wishes to focus on dress in order to explore issues of sociocultural change and negotiation

of modernity in Cyprus during the British Period. Dress, which has been aptly characterised as a form of “social skin” and as part of the “technologies of the self”, comprises one of the strongest visual, self-communicative mechanisms, and as such it is considered especially suitable for studying and understanding sociocultural processes and the construction of identity through material culture. Drawing on evidence from an array of primary sources (extant dress items, archival and press material, photographs, and oral testimonies), the analysis focuses on matters of dress typology and use in order to study the material culture mechanisms through which social agents, from the level of the individual to the level of regional and/or island-wide social groups, choose to negotiate their identity in a transitional period.

6 EVERYDAY AESTHETICS: SENSORY EXPERIENCE AND MEDIEVAL MATERIAL CULTURE

**Abstract author(s):** Friedrich, Matthias (University of Vienna, Department of Prehistoric and Historical Archaeology)

**Abstract format:** Oral

Aesthetics, broadly defined as the evaluation of sensory experience and perception, is often limited to the study of art appreciation. In this line of thought, ordinary and ‘everyday’ objects—which constitute most of the archaeological record, such as pottery—are excluded from aesthetic consideration. Recent debates in contemporary aesthetics, however, also emphasized ‘everyday’ aesthetics as part of human responses to sensory experience. This paper tries to blur such boundaries through a comparative approach, exploring the concept of everyday aesthetic experience for the archaeological study of material culture.

This includes an assessment of relevant theoretical approaches within and outside of archaeology. The focus lies, however, on exemplifying aesthetics of the ‘everyday’ through a range of brief case studies, ranging mostly from late Antiquity to early modern Europe: this includes, for example, the shininess and visual reflection of early medieval dress accessories, the texture of medieval pottery, the warmth of late medieval stove tiles, and the smell of clay tobacco pipes.

417 CONNECTIVITY IN LATER PREHISTORIC EUROPE: MOBILITY, TRADE AND INTERACTION FROM THE 2ND MILLENNIUM BCE TO THE 1ST MILLENNIUM AD

**Theme:** 4. Globalisation and archaeology

**Organisers:** Gorgues, Alexis (University Bordeaux Montaigne) - Büster, Lindsey (Department of Archaeology) - Črešnar, Matija (University of Ljubljana) - Melheim, Lene (University of Oslo; Museum of Cultural History) - Poigt, Thibaud (UMR 5607 Ausonius - Bordeaux; UMR 5608 Traces - Toulouse)

**Format:** Regular session

Recent scientific and methodological advances have reshaped our understanding of ancient mobility. Although patterns of far-reaching contact have long been hypothesised, DNA and isotope analyses have demonstrated that mobility was much more widespread than has traditionally been supposed, and that these networks were complex and diverse. Furthermore, artefact studies (including the more routine implementation of materials science and provenance studies) are demonstrating the ubiquity of long-distance trade networks, and the different ways trade (here defined as any peaceful way of exchanging materials, commodities or services) was made.

Such strong and sustained levels of connectivity between different regions for varying durations could only have been achieved with a certain degree of agreement over common social and economic rules, which must have been achieved on the basis of an enduring shared practice, particularly in pre-literate societies where written laws did not exist. As such, informal institutions – i.e. those not enforced by law but based on a common sense of honour and trust – must have been sufficiently strong to allow for swift travel and convenient interaction, within or outwith a formal economic framework.

This session invites contributions examining the materiality of long-distance networks across Continental, Atlantic, Northern and pre-classical Mediterranean Europe, from the beginning of the Bronze Age until the appearance of written law. Papers examining patterns of trade, exchange and mobility through systems of material exchange or distribution, the transmission of ideas (related to, for example, technological or symbolic activities) and bioarchaeological methods are welcome, as are those which consider these processes from a range of perspectives: theoretical models, case studies, regional synthesis, etc.

ABSTRACTS:

1 THE “MOVING LANDSCAPE” OF THE AEGEAN LATE BRONZE AGE IN THE ARGOLID, GREECE

**Abstract author(s):** Brysbaert, Ann (Leiden University, Faculty of Archaeology)

**Abstract format:** Oral

In past pre-industrial societies featuring large-scale building projects, extensive manual labour was invested during the entire chaîne opératoire of construction. This synthesis focuses on the cost of a range of labour activities during the 13th century BCE in the Aegean Late Bronze Age. Following Janet DeLaine’s (1997) example, this paper aims to move “beyond the calculation of average and peak overall man-power requirements to consider the workforce as individuals, thereby allowing a closer estimation of the size and nature of the man-power”. Prehistoric people in the Argolid were interconnected through their multiple daily tasks while remaining resilient before the accumulation of adverse events around 1200-1190 BCE. In doing so, I investigate labour costs required for mon-

umental and domestic house building, infrastructure provision, tomb digging, pottery production, and several agricultural activities. Next, their joint implications to society are compared and discussed in light of the entire taskscape which mobilised large groups of people on a daily basis, and far beyond the regional scale, if both elites and commoners are taken into the equation.

This research highlights that rural landscapes and their populace formed the backbone connector of these Late Mycenaean pre-industrial Argolid-based societies. Understanding energy expenditure from a bottom-up perspective suggests large levels of responsibility in the hands of farmers and workers rather than allowing elites to rule the scene continuously. Since most ancient societies were based on subsistence economies, important decision-making was a daily balancing act between building work, agriculture and many craft activities, thus invoking multiple scales of connection. The enduring long-term labour practices in which human and other energy was expended as sustained levels of interconnected work tasks, there is no doubt that the completed structures, but also the process of making them, exuded power that would have rippled throughout the entire society and through the individual people.

2 THE HOARD FINDS OF THE LATE BRONZE AGE OF CYPRUS IN THEIR EASTERN MEDITERRANEAN CONTEXT

**Abstract author(s):** Bartelheim, Martin (Universität Tübingen) - Kızılduman, Bülent (Eastern Mediterranean University) - Müller, Uwe (Universität Tübingen)

**Abstract format:** Oral

From the Late Bronze Age in Cyprus we know an unusually large number of hoards compared to other Eastern Mediterranean regions. They were mostly found in settlement areas and often contain high-quality bronzes. In the past decades, there has been an intensive discussion about how these deposits should be interpreted. In addition to being understood as hiding places for precious possessions in times of crisis, they have above all been regarded as deliberate deposits in the sense of sacrifices. On the basis of a new comprehensive treatment of the Cypriot hoard finds of the Late Bronze Age and against the background of the current discussion on the characterisation of the phenomenon of Bronze Age hoards, their interpretation will be debated in this lecture. The characteristics of the Cypriot hoards and their cultural embedding in Cyprus will be compared with the situation in other regions of the Eastern Mediterranean. This forms the basis for addressing the question whether they are visual manifestations of trans-regional cultural connectivity in the East Mediterranean and markers for the existence of networks with similar rules and ideas, or are rather expressions of similar and possibly also simultaneous behaviour in times of crisis.

3 THE ORIGINS OF METAL: STRATEGIES FOR SOURCING SUPPLIES AND CONNECTIVITY IN THE BALEARIC ISLANDS DURING THE BRONZE AGE

**Abstract author(s):** Perelló Mateo, Laura - Llull Estarellas, Bartomeu - Calvo Trias, Manuel (University of Balearic Islands)

**Abstract format:** Oral

The Balearic archipelago is the westernmost group of islands in the Mediterranean. Archaeological data shows that the communities that inhabited the islands were well connected during the Bronze Age. One of the clearest indications of this is the existence of local bronze metallurgy, even though there was no tin in the Balearics. At the same time, based on the available lead isotope data for minerals and bronze metals, this paper explores the different links that the islands may have had with other geographical regions during this period.

Hence, three levels of connectivity can be established: 1) among the communities of the different islands that make up the archipelago; 2) between the islands and the nearest Mediterranean regions, such as the south, east and north-east of the Iberian Peninsula and the south of France; 3) long distance links, with the existence of objects whose metal is possibly of Sardinian, Alpine and Central European origin.

4 METAL EXCHANGE AND CONNECTIVITY: EVIDENCE FROM NEW MULTIDISCIPLINARY RESEARCH

**Abstract author(s):** Melheim, Lene (Museum of Cultural History University of Oslo) - Ling, Johan (University of Gothenburg) - Grandin, Lena (Arkeologerna, Statens Historiska Museum) - Hjärthner-Holdar, Eva (Independent researcher)

**Abstract format:** Oral

Few areas in temperate Europe exhibit such accumulated densities of bronze as southern Scandinavia, with an estimated yearly consumption of c. 1 ton, and yet, recent lead isotope and chemical analyses have established that metals were imported in large amounts from distant regions in Europe despite local availability of copper. Thus, a key issue in current research is how the peripheral polities in northern Europe were able to attract so much metal from distant regions. Recent research has argued that southern Scandinavia became integrated into European long-distance trading networks during the 2nd millennium BCE, and that this development had a profound impact on the evolution and complexity of local societies in Scandinavia.

This paper will present and sum up the results of a research programme using lead isotope and chemical analysis to establish the provenance of c. 250 Scandinavian bronzes. The interpretation of the dataset suggests a complex picture of possible connections between Scandinavia and Europe 1700-1000 BCE. Overall, the varied compositions and origins of copper identified in artefacts dated to the earliest phases indicate a dynamic diffusion of metals across Europe with a variety of sources. It is indicated, however, that trade networks became more stable around 1500 BC, when the sea-based supply of copper from Great Orme in Wales into Scandinavia declined, and suppliers in the southeastern Alps gained in importance. This paper addresses questions related to the

social mechanisms behind the trading networks. It is argued that the participation of Nordic groups in the metal trade was a result of their ability to organise and capitalise on a maritime mode of production reliant on trading and raiding. In this system, surplus production from agriculture enabled chiefs to invest in boats and crew for long-distance exchange.

5 **ISOTOPIC AND GENETIC EXPLORATIONS OF CROSS-CHANNEL CONNECTIVITY IN BRONZE AGE AND IRON AGE KENT**

**Abstract author(s):** Bleasdale, Madeleine - Fischer, Claire-Elise - Büster, Lindsey (University of York) - Evans, Jane (National Environmental Isotope Facility, British Geological Survey) - McKinley, Jacqueline (Wessex Archaeology) - Reich, David (Department of Genetics, Harvard Medical School) - Armit, Ian (University of York)

**Abstract format:** Oral

Persistent long-distance networks of connectivity between Britain and the Continent have been evidenced archaeologically through shared aspects of material culture. During the Middle and Late Bronze Ages, cross-channel exchanges resulted in the formation of a broad, common cultural entity on both sides of the Channel: the “Manche—Mer du Nord (MMN) complex”. Such interactions persisted during the Iron Age, becoming more visible in the Late Iron Age, when new continental imports (e.g. Mediterranean pottery) reached southern Britain. Lastly, as the Roman provinces expanded, textual sources frequently evoke resources originating from northwestern France and southern Britain.

Existing sources demonstrate that, rather than being a barrier, the channel was a dynamic maritime axis during the Bronze and Iron Age. Nevertheless, reconstructing the nature of cross-channel interactions remains challenging. In recent years, aDNA has confirmed movements between the Continent and Britain (Fischer et al., 2018), and strontium (<sup>87</sup>Sr/<sup>86</sup>Sr) and oxygen ( $\delta$ 18O) isotope measurements of tooth enamel have identified potential migrants in southern Britain (McKinley et al., 2014).

This paper synthesizes existing and new multiproxy data at a regional-scale, focusing on sites from Kent, including Margetts Pit and Cliffs End Farm. Given its proximity to the Channel, Kent is an important locale for exploring cross-channel connections. Indeed, several individuals from Cliffs End Farm have already yielded isotope measurements demonstrating they spent their childhood outside of Britain. New aDNA analysis targeting individuals from Cliffs End Farm and elsewhere has now identified the continent, and perhaps France as a potential point of origin for incoming individuals.

The revaluation of pre-existing data, combined with new analysis demonstrate that Kent was an important crossroads between continental Europe and Britain throughout the Bronze and the Iron Ages. Our study also highlights the strength of multi-proxy approaches for reconstructing the timing and tempo of mobility, and individual life histories.

6 **PERFORMING ENCOUNTER: THE INSTITUTIONS OF CONNECTIVITY IN BRONZE AND IRON AGE EUROPE**

**Abstract author(s):** Gorgues, Alexis (University of Bordeaux Montaigne)

**Abstract format:** Oral

Data on human mobility and commodity exchange have clearly demonstrated that Bronze and Iron Age European societies experienced high levels of connectivity, and that long-distance interactions were frequent. Patterns of interaction were shared across large geographical areas, with supra-local institutions providing later prehistoric societies with a framework of mutual trust. Using a series of case studies, this paper will discuss the nature of these institutions. It will first distinguish between different spheres of interaction (trade, diplomacy, education, craftworkers mobility, etc.), before demonstrating that most of them were embedded in a institutional frameworks that regulated interpersonal relationships. It will then propose that rejection or denial of these interactions was also governed by institutionalized processes responsible for regulating mobility.

Such institutional frameworks allowed for the creation and maintenance of multi-directional networks of interaction, in which people rather than places were the nodes. The paper will conclude by highlighting the importance of long-range connectivity in late prehistoric societies as a competitive process which was central to identity building at a number of scales.

7 **WIDESPREAD ELEMENTS OF SOLAR SYMBOLISM FROM THE LATE BRONZE AND EARLY IRONAGE. TRACING CONNECTIONS BETWEEN SOUTHERNSCANDINAVIA AND THE CIRCUM-ALPINE AREA**

**Abstract author(s):** Wirth, Stefan (Université de Bourgogne)

**Abstract format:** Oral

Over a long period, distant regions of prehistoric Europe have shared specific elements of an iconography centering on solar symbolism. In the search for a cosmological narrative underlying this material evidence, we aim to bring together fragments reflecting what seems to have been a widespread and long lasting oral tradition. In order to do so, we will consider selected objects and assemblages potentially embodying mythologems, dating to the late Bronze and early Iron Age.

The well-known Bronze Age burials at Skallerup (Sjælland) and Peckatel (Mecklenburg) will serve as the starting point of our survey. These famous discoveries show early evidence of a distinctive arrangement combining a large movable metal vessel with bird imagery. At Skallerup, the wheeled cauldron was destined to accommodate the ashes of the deceased. We will follow this phenomenon of extraordinary burials, additionally qualified by the presence of rare gold ornament, until the transition from the late Bronze to the early Iron Age. Examining in a complementary way other characteristic assemblages, including metal hoards, we will focus on the ritual use, which was at that time made of decorated metal vessels.

Finally, we will also point out a fundamental change perceivable in the shape and decoration of a number of types of bronzes occurring north of the Alps around 900 BC and entailing a new fashion of expressing the same eternal subject matter while certain features of traditional form persist. By analyzing the success of the basic structure of the two- and three-dimensional images in question, we hope to get closer to understanding the pertinent point that is the wide acceptance and longevity of what we intent to define as a unique configuration related to cognitive representation.

8 **PEOPLE ON THE MOVE: EARLY IRON AGE ENCOUNTERS ACROSS THE ALPS**

**Abstract author(s):** Moetsch, Angela (Max Planck Institute for the Science of Human History; Max Planck Institute for Evolutionary Anthropology)

**Abstract format:** Oral

Evidence for contact and exchange between the Westhallstattkreis and Northern Italy has been documented for a long time. Traditionally, it is described by either the import of southern artefacts or by locally made artefacts or features that show Mediterranean influence in shape, design, and/or technique found in archaeological contexts north of the Alps. The view from the south, implicating the more active role of the agents of Mediterranean cultures, often still prevails. Scenarios describing the nature of such exchange include institutionalized long distance trade via commercial settlements and/or middlemen, but also the travel of individuals, e.g. craftspersons, who left their home and came in direct contact with a foreign cultural environment. However, reliable evidence for direct encounter is only rarely attested and the nature of interactions often has to remain a theoretical consideration. In my presentation I will highlight the presence of people who actually crossed the Alps in a southward direction to live within Northern Italian communities.

9 **ANATOMY OF AN EARLY IRON AGE GRYPHON**

**Abstract author(s):** Czifra, Szabolcs - Kreiter, Attila - Viktorik, Orsolya (Hungarian National Museum - Magyar Nemzeti Múzeum)

**Abstract format:** Oral

More than a decade ago fragments of a decorated large clay object were unearthed in a settlement feature of the Early Iron Age Hallstatt culture during a preventive excavation at Báticasék (W Hungary). After restoration, the artefact reborn as a large clay seal, characteristic of the Scythian influenced Vekerzug culture. In addition to the fact, that the artefact’s size is much larger than similar clay seals, it has a unique decoration in the form of two mythical animals. Based on the form of diagnostic parts of the animals, e.g.

the head, body, legs and tail the large winged animals can be determined as gryphons. This paper aims to explore the origin and meaning of the unique artefact by traditional formal and stylistic investigations, which is supplemented by thin-section petrographic analysis. As the origin and meaning of the gryphon image lead us far beyond the Carpathian Basin, the orientalising motif is studied within broader time and geographical frames. Nevertheless, the formal overview of the object will largely focus on the Carpathian Basin, as similar clay seals are primarily associated with Vekerzug women. Concerning the fact that these items had a characteristic role in constructing female identity, special attention will be dedicated to the communication networks in the Carpathian Basin in the 7th-5th centuries BC. Thin section petrography is used to analyse the fabric of the seal and compare it with local sediments, collected at the site, to reveal valuable information on its provenance.

10 **MEETING AROUND THE CAULDRON: CONNECTIONS BETWEEN SCANDINAVIA AND CONTINENTAL EUROPE DURING MID-FIRST MILLENNIUM BC EXPLORED THROUGH THE HASSLE HOARD, SWEDEN**

**Abstract author(s):** Sörman, Anna (Stockholm University) - Ojala, Karin (Stockholm University; Uppsala University)

**Abstract format:** Oral

In 1936 an intriguing deposition dating to the Bronze Age-Iron Age transition (c. 500 BC) was found in a river bed in Hassle in south-eastern Sweden. It contains a rare combination of foreign metalwork: two bent Hallstatt swords of Mindelheim type, two rippenzisten/ciste a cordoni buckets, two small hooks and twelve ornamental bronze discs, along with some unidentifiable fragments - all found inside a reworked and heavily repaired cauldron, possibly originating from Italy or Greece.

While the discs could be of either local Nordic or Central European production, the other items clearly belong to a high-status sphere of exotic goods, linking Scandinavia to the Continent. The origin and trajectory of these objects are now being examined by means of chemical composition and lead isotope signatures as well as renewed comparative studies.

This paper presents the working hypotheses and preliminary results concerning these objects’ possible areas of production and history of use. A special focus is placed on the buckets and cauldron as equipment for communal meals or drinking ceremonies. Sacrifices of metal bowls and cauldrons appeared in Scandinavia from the mid Bronze Age and up into the Iron Age. The wide-spread distribution and geographical displacement of hammered metal vessels testify to far-reaching exchange.

This paper highlights feasting as an arena where travelers were exposed to foreign objects. Conspicuous metal containers upheld a meeting culture in which they were highly visible and easily recognizable elements. The serving vessels can be understood as ‘encounter material’, brought to Scandinavia due to its familiar form and role in shared socio-political practices rather than as a foreign exotica.

RITUAL MOBILITY, NETWORKS AND INTERACTION IN IBERIAN IRON AGE SANCTUARIES (3RD-1ST CENTS. BC)

**Abstract author(s):** Grau, Ignacio (Institute of Archaeology and Historical Heritage. University of Alicante)

**Abstract format:** Oral

This paper present recent archaeological, typological and archaeometrical studies on the votives offered in sanctuaries of the Eastern Iberia Iron Age, in modern Valencia Region, Spain. The analysis had proved the existence of clearly established groups of local and non-local offerings. According to these results we can trace the influence of the sanctuaries in their local landscape but also to expand the scale of interaction to some larger regional areas. This opens up opportunities for analysing ritual mobility, networks and interactions at different scales. The data show that there is a clear evidence of ritual practices shared within the communities of different territories in the region. The offering of identical objects that circulated and were deposited in diverse sanctuaries opens new prospective for the interpretation of the cult places sites and their role in building local and regional identities. At the same time, the data is employed to trace social interactions between specific places and regions according to this ritual mobility and encounters at the cult places.

MAPPING MIDGARD. RECONSTRUCTING MENTAL GEOGRAPHIES OF VIKING AGE SEAFARERS

**Abstract author(s):** Jarrett, Greer (Lund University)

**Abstract format:** Oral

Conventional representation techniques in archaeology have proven to be less than ideal for exploring the experiences and world-views of cultures distinct from our own. Over the last few decades a range of alternative methods have received scholarly attention, originating both in the rise of digital technologies and in the efforts of subaltern communities to illustrate their beliefs, histories and land claims. Drawing on this creative diversity, this project explores the mental geographies of Viking Age seafarers, proposing a series of alternative approaches for representing these using experimental archaeology, critical cartography, and digital mapping techniques. It is hoped that alternative representations will give rise to new interpretations and new possibilities for Viking Age archaeology, contributing to debates about sailing routes, geopolitical relationships, settlement and migration patterns and the relationships between seascapes and cosmologies.

The project draws on the wealth of experimental scholarship conducted aboard reconstructed Viking Age ships as a source of experiential and technical data. Phenomenological and ethnographic fieldwork shall be performed aboard similar reconstructed vessels to select and quantify the most fundamental experiential variables related to Viking Age seafaring. These data shall be used to build models in the form of maps. Factors that are rarely included in conventional cartography such as movement, time and sensory experience shall be the focus of these maps. They shall then be evaluated based on their potential for contributing to wider research questions in Viking archaeology such as those mentioned above. This project is still in a very early stage, but exciting inroads have been made into experiential mapping using isochronal cartography, and fieldwork in Norway is due to begin in August. It is hoped that the project will illustrate the potential of digital technologies for promoting intercultural dialogue and research, and offer an alternative window into the Norse world.

SHOULD I STAY OR SHOULD I GO? PATTERNS OF MOBILITY IN PREHISTORIC SEDENTARY AND PASTORALIST SOCIETIES

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Scharl, Silviane (Institute of Prehistoric Archaeology, University of Cologne) - Hofmann, Daniela (Department of Archaeology, History, Cultural Studies and Religion, University of Bergen) - Gerling, Claudia (Integrative Prehistory and Archaeological Science - IPAS, University of Basel)

**Format:** Regular session

Not so long ago, one might have been forgiven for thinking that people in prehistoric sedentary societies did not move around so much. Yet we now command an overwhelming amount of data which seem to show the exact opposite and have blurred the distinction between sedentary and more mobile ways of life. Ancient DNA, isotopes and new insights from human/animal osteology have come to supplement traditional artefact studies to create a picture of people – be it individuals, groups of people or larger social units –, animals and things constantly on the move – for shorter or longer distances, over varying amounts of time, and for widely different reasons. Our main challenge now is how to make sense of this diversity.

Mobility occurs at different spatial scales, from short distances travelled for obtaining resources to long travels, perhaps among complete strangers. It can happen at very different rhythms, from daily or seasonal rounds, to settlement relocation at yearly or decadal frequencies, to once-in-a-lifetime journeys. Tracing and identifying these scales, let alone agents and their reasons, makes huge demands on our data, both scientific (dating methods, isotopes, artefact sourcing studies, DNA etc.) and more traditionally archaeological (stylistic comparisons, data concerning settlement/economy etc.). However, this necessary attention to detail can make it hard to compare results and patterns across case studies, in order to identify recurrent trends.

In this session, we aim to bring together scholars who are working in particular prehistoric contexts in which different forms of mobility co-exist. We would like to focus on how these different mobilities come together to form a particular way of life or dynamic

system, and what variables are responsible for creating/changing these patterns. We hope that a broad comparison of synthetic case studies across prehistory can help us grasp the bigger picture.

ABSTRACTS:

INTRODUCTION: SHOULD I STAY OR SHOULD I GO? PATTERNS OF MOBILITY IN SEDENTARY AND PASTORALIST SOCIETIES

**Abstract author(s):** Scharl, Silviane (Institute of Prehistoric Archaeology, Cologne University) - Gerling, Claudia (Integrative Prehistory and Archaeological Science - IPAS, University of Basel) - Hofmann, Daniela (Department of Archaeology, History, Cultural Studies and Religion, University of Bergen)

**Abstract format:** Oral

There is now a wealth of case studies showing that mobility in sedentary societies was far from unusual, while it can also take a wide variety of forms in pastoralist groups. These patterns of mobility operate at various temporal, spatial and social scales. There are long-term strategies which become embedded in a society's way of life, as well as short-term reactions to changing circumstances and one-off exploratory voyages. There are journeys which cover many hundreds of kilometres and those which may just involve a day's walk. And finally, large groups of people can sometimes move together, while at other times it is small collectives or even just single individuals which are on the move.

All this is now amply documented, both through traditional archaeological case studies (imported goods, diffusion of styles etc.) and through newer bioarchaeological models. Yet most of the time, we look at just one component of this complex system. Using selected case studies mainly from Neolithic Europe, we set the scene for the remainder of the session by asking how these different axes intersect and what sorts of questions remain to be tackled before we can draw a more comprehensive picture of past mobility as a durable component (rather than an exceptional behaviour) of prehistoric life.

RETHINKING THE SUB-NEOLITHIC IN NORWAY: SUBMISSIVE AND VULGAR OR CREATIVE AND AFFLUENT?

**Abstract author(s):** Mansrud, Anja (Museum of Archaeology, University of Stavanger) - Nielsen, Svein (Museum of Cultural History, University of Oslo) - Præsch-Danielsen, Lisbeth (Museum of Archaeology, University of Stavanger) - Berg-Hansen, Inger Marie (Museum of Cultural History, University of Oslo) - Austvoll, Knut Ivar (IAKH, University of Oslo)

**Abstract format:** Oral

For many years the Middle Neolithic (3300-2350 cal BCE) forager settlements on the central Skagerrak coast was the epitome of the sub-Neolithic phenomenon in Norway. The sub-Neolithic is traditionally defined as societies existing in Neolithic times that rejected a Neolithic ideology. They appear in many forms in Northern Europe during the fourth millennium BCE; from Horgen in the south to Pitted Ware in the north; from Wartberg in the west to Zedmar in the east. New analyses of zooarchaeological, palynological, geological and archaeological evidences from the central Skagerrak coast in Norway strongly encourages a rethinking of the sub-Neolithic in this region. Rather than a submissive and vulgar remnant from Mesolithic times, as was previously thought of these settlements, we discover a resilient, creative and affluent society, well adapted to its local environment. We reconstruct a model of seasonal mobility and flexible utilisation of resources, ranging between e.g. pottery production and exploitation of Atlantic Bluefin Tuna on the coast, and small-scale crop growing in the hinterlands. There is also evidence of long-distance trade and coastal travelling around the Skagerrak and Kattegat Sea. The diverse mobility made these societies robust despite environmental variation and changes in living conditions over time. Finally, we suggest a redefinition of the sub-Neolithic in this region from a 'Neolithic culture' to an ecohistorical regime, presupposing that complex ecodynamic relations in the past resulted in non-linear and contingent historical trajectories.

SULPHUR ISOTOPES, ENVIRONMENT, LOCAL MOBILITY, AND THE STONE AGE MARIAGER FJORD, EASTERN JUTLAND, DENMARK

**Abstract author(s):** Gron, Kurt - Gröcke, Darren - Winton, Anna (Durham University) - Robson, Harry (University of York)

**Abstract format:** Oral

Until recently, sulphur ( $\delta^{34}\text{S}$ ) isotope analysis of bone collagen was not routinely undertaken in the archaeological sciences; however, its application is becoming increasingly widespread. Sulphur isotope values potentially reflect a number of factors, including diet, geology, ingested water, and coastal proximity. Such analyses are therefore of relevance to many questions regarding Stone Age coastal environmental reconstruction, including human and animal mobility, ecosystem characterisation, salinity gradients, and in understanding prehistoric local animal behavioural ecology. Here, we present a series of sulphur isotope analyses, together with more routine carbon ( $\delta^{13}\text{C}$ ) and nitrogen ( $\delta^{15}\text{N}$ ) isotope analyses, to a number of archaeological taxa from the Mariager Fjord in Eastern Denmark, in order to understand the Late Mesolithic and Early Neolithic environmental conditions in the area. The fjord system is characterised by the presence of a substantial number of Late Mesolithic and Early Neolithic shell middens along its length, indicating a long-term human presence. Results indicate that sulphur isotope analyses reveal variation that may permit a better

understanding of how different microhabitats were exploited, and the local character of the movement of both human groups and resources.

4 **STRONTIUM ISOTOPE (87SR/86SR) ANALYSIS REVEALS MOBILITY PATTERNS AMONG STONE AND BRONZE AGE POPULATIONS IN THE SOUTHEASTERN BALTIC**

**Abstract author(s):** Piliciauskas, Gytis - Simčėnka, Edvardas (Archaeology Department, Lithuanian Institute of History) - Kozakaitė, Justina (Faculty of Medicine, Vilnius University) - Piličiauskienė, Giedrė (Faculty of History, Vilnius University) - Robson, Harry (Department of Archaeology, the University of York)

**Abstract format:** Oral

Strontium isotope (87Sr/86Sr) analysis has been successfully applied to archaeological materials for more than 30 years to understand prehistoric mobility. Despite this, prehistoric skeletal remains from Eastern Europe have not received the same attention as other regions of Europe meaning that the majority of interpretations concerning prehistoric human mobility are largely based on material culture, physical anthropology and very seldom aDNA data. In this presentation we present the first 87Sr/86Sr measurements obtained from 40 Stone Age human individuals from the present-day territory of Lithuania as well as measurements obtained from faunal remains serving as local baselines. The preliminary results demonstrate a higher degree of mobility among inland hunter-gatherers compared with those residing on the coast as well as subsequent farmers dating to the Iron Age. In addition, we have identified several ‘migrants’ among the Mesolithic and Neolithic individuals, which, it would appear, are derived from region(s) outside of the present-day territory of Lithuania. Lastly, we compared these data with other strontium isotopic studies undertaken on Stone and Bronze Age human remains throughout Europe to place the results into a wider context.

5 **MOBILITY AND SEDENTARY IN THE STEPPE BRONZE AGE (ON THE EXAMPLE OF ONE ARCHAEOLOGICAL MICRODISTRICT IN THE SOUTHERN TRANS-URALS, RUSSIA)**

**Abstract author(s):** Epimakhov, Andrey (South Ural State University; Institute of History and Archaeology UB RAS) - Kupriyanova, Elena (Chelyabinsk State University)

**Abstract format:** Oral

Local Bronze Age is represented by numerous archaeological cultures (Sintashta, Abashevo, Petrovka, Srubnaya, Andronovo, etc.). All of them are characterized by a similar life support system based on complex animal husbandry. There are also traces of local ore mining and metal smelting. Traces of fortified and unfortified settlements were studied well for all cultures. The nature of economic activity inevitably implies the mobility of people and animals. Testing the scale and form of mobility requires a variety of archaeological and scientific methods. This work has begun for the microdistrict near the village of Stepnoye (Chelyabinsk Region). The first step was to create a basemap of strontium isotopes to determine the extent of local mobility and the presence of exchange operations. Archaeological data illustrate the mosaic nature of material culture (first of all, ceramics), to some extent, burial rituals. Some of the finds have non-local features (Seima-Turbino complex), the closest analogies of which are located several hundred kilometers away. The widespread use of radiocarbon dating made it possible to establish that a significant part of cultural traditions existed simultaneously, which is well traced back to the beginning of the 2nd millennium calBC. An analysis of the inventory typology, stratigraphy, and planigraphy of burial sites also confirms the continuity of some cultures. The first results of DNA-studies confirmed the heterogeneity of the population. This heterogeneity could have been partially formed during the migration of different groups at the end of the 3rd millennium calBC. Thus, the archaeological data for the microdistrict illustrate traces of mobility of different scales, caused by different factors - migrations, trade relations, economic activity (animal husbandry and mining of copper ore). The heterogeneity of the collectives was supposed to facilitate their inclusion in the systems of movement and exchange of various scales, from global to local.

6 **A TALE OF EARLY NOMADISM? SUBSISTENCE MOBILITY WITHIN THE YAMNAYA CULTURE IN THE NORTHERN BLACK SEA STEPPE**

**Abstract author(s):** Riesenberger, Martin - Kaiser, Elke (Institut für Prähistorische Archäologie, Freie Universität Berlin)

**Abstract format:** Oral

Recently an increasing number of ancient DNA-studies highlighted the key role that the Yamnaya culture of the Eastern European steppe played in the last major genetic turnover in Europe. In light of these apparently large-scale population dynamics that took place during the transition from the Eneolithic to the Bronze Age the academic research often focused on migration as a major factor in terms of mobility.

Although these steppe communities were also repeatedly described as early pastoral nomads the character of the mobility in the sphere of Yamnaya subsistence economy remains still widely understudied. As an attempt to reduce this research gap we focus in our study on the examination of the level of this subsistence mobility.

In our paper we will present the case study of Generalka-2 – a Yamnaya settlement in the lower Dnieper area. Its faunal record is predominated by domestic cattle. Livestock enamel was sampled sequentially for carbon and oxygen isotopes ratios. These function as proxies for the proportions of C3- versus C4-plants within the diet as well an approximation to the seasonal temperature. Furthermore strontium isotope ratios were measured to detect seasonal changes of locality.

The results revealed a notable seasonal variability in the birth timing of the animals implying a non-uniform herd management strategy. The strontium isotope ratios show seasonal differences as well. Additional reference data might enable us to clarify the spatial meaning of these results. This is – to our knowledge – the first study that addresses the question of seasonal mobility of domestic animals with the help of sequential isotope data within the Eastern European Steppe Belt. It outlines considerable potential in the research aiming to characterize the pastoral subsistence strategies, modes of ‘domestic’ mobility and the manner of landscape use of communities attributed to the Yamnaya complex.

7 **ISOTOPIC INVESTIGATIONS OF HUNTING ACTIVITIES IN NEOLITHIC SWITZERLAND**

**Abstract author(s):** Gerling, Claudia (Integrative Prehistory and Archaeological Science, Department of Environmental Sciences, University of Basel) - Doppler, Thomas (Kantonsarchäologie Aargau, Brugg) - Knipper, Corina (Curt-Engelhorn-Zentrum Archäometrie - CEZA, Mannheim) - Pike, Alistair (Department of Archaeology, University of Southampton) - Lehmann, Moritz (Biogeochemistry, Department of Environmental Sciences, University of Basel) - Schibler, Jörg (Integrative Prehistory and Archaeological Science, Department of Environmental Sciences, University of Basel)

**Abstract format:** Oral

Hunting was a key economic strategy in the Pre-Neolithic periods and remained – aside the herding of domestic animals – important during the Neolithic. Given that hunting required a certain degree of mobility of at least some part of the communities, constraints on hunting activities also yield indirect information on the “everyday” mobility in sedentary Neolithic societies.

In NE-Switzerland, archaeozoological evidence further suggests that the economic strategy to hunt has been of particular importance during times of climatic aggravations, when crops failed and domestic animal foddering resources became limited, e.g. during the food crisis of the 37th century BCE attested for the pre-alpine lakeshore settlements. In a case study, we explored the role of hunting in communities living at the Lakes Constance and Zurich during the 4th and 3rd millennia BCE. By analysing red-deer tooth enamel for strontium and oxygen and human bone for carbon and nitrogen stable isotope ratios, we gained insights into the Neolithic hunting ranges and mobility, as well as the role wild animal products played in the human diet at the time.

In this contribution, we present and discuss the results of the case study, putting them into the wider context of the diversity of mobility patterns related to the economy of the pre-alpine Neolithic wetland sites.

8 **NOT JUST A LOCAL SITE FOR LOCAL PEOPLE. PATTERNS OF MOBILITY IN LATER NEOLITHIC BAVARIA**

**Abstract author(s):** Hofmann, Daniela (University of Bergen) - Szilagyi, Marton (Eötvös Loránd University Budapest) - Grupe, Gisela - Perutka, Anna - Schreil, Franziska (LMU Muenchen) - Kegler-Graiewski, Nicole (Independent Researcher) - Helfert, Markus (University of Frankfurt) - Ramminger, Britta (University of Hamburg)

**Abstract format:** Oral

The enclosure at Riedling (c. 4300-4000 cal BC) in Bavaria stands out due to many human remains and several striking examples of depositional practices involving large amounts of complete vessels and animal bone. In the course of analysis, these activities and people reinforced the striking range of contacts and connections previously suggested for the local Münchshöfen culture, as well as revealing some new ones. The pottery shows striking links to cultural phenomena further east, in modern-day Hungary or the Czech Republic amongst others. In contrast, some of the human individuals appear to have been regionally mobile, utilising upland resources in a more concerted fashion than previously. There is no apparent distinction in treatment or dietary intake between isotopic locals and outsiders, suggesting that this was not an important defining criterion for inclusion in the community of users at Riedling. Rather, the Riedling enclosure and the activities that took place there could have functioned a mechanism for integrating and people and things of diverse origins, mostly mediated through the consumption of food and drink.

9 **A CROSS-DISCIPLINARY VIEW ON RESIDENTIAL MOBILITY DURING THE 5TH MIL. BC IN CENTRAL EUROPE**

**Abstract author(s):** Scharl, Silvine - Krewer, Elisabeth (Institute of Prehistoric Archaeology, Cologne University)

**Abstract format:** Oral

The beginning of agriculture in Central Europe marks the beginning of a sedentary way of life in terms of living in one place year-round. For the early farming societies the archaeological record reflects rather long-lasting settlement structures. We find numerous settlements that have been occupied for several generations sometimes even hundreds of years. During the second half of the 5th mil BC, however, this sedentary way of life is transformed. Traces of settlements let alone houses almost disappear and it is mostly through ditched enclosures that the Neolithic population is still visible for us. This is interpreted as a reflection of increased residential mobility. So far, however, we have almost no isotopic studies on this period that allow for an evaluation of this idea on the level of individual actors. Therefore, six burials from the site of Altdorf (Landshut) in Southern Bavaria were sampled to get an insight into diet habits and mobility patterns during the 5th mil B.C. The results of the strontium isotope analysis show significant differences between the individuals from the so-called Oberlauterbach group (c. 4750-4500 BC) and the Muenchshoeften Culture (c. 4500-4000 BC). Whereas the male individuals from the Oberlauterbach group show local isotopic signatures, all individuals from the Muenchshoeften-Culture seem to exhibit higher mobility, i.e. they had changed residence in the course of their lifetime before they moved to Altdorf (Landshut).

10 These results will be set into a wider context by looking at further traces for residential mobility in the archaeological record in order to get a bigger picture for Central Europe at that time.

USTICA (SICILY), THE NEOLITHIC JOURNEY: FAR-AWAY ISLAND OR NETWORK NODE?

**Abstract author(s):** Speciale, Claudia (Istituto Nazionale di Geofisica e Vulcanologia; University of Las Palmas) - Battaglia, Giuseppina (Soprintendenza per i BB.CC. di Palermo, Sicily) - Larosa, Nunzia (School of Humanities, Arts, and Social Sciences, University of New England) - de Vita, Sandro - Di Vito, Mauro - Arienzo, Ilenia (Istituto Nazionale di Geofisica e Vulcanologia) - Veltre, Virginia - Battistini, Andrea - De Angelis, Flavio (Centre of Molecular Anthropology for Ancient DNA Studies University of Rome Tor Vergata)

**Abstract format:** Oral

The main aim of this paper is to cross the data obtained with the geological investigation, the archaeological and geochemical analyses on human bones and material found in the Neolithic site of Piano dei Cardoni, to deepen the knowledge about the origin and entity of the first human population of Ustica and define its connectivity with the close and far regions of Central Mediterranean.

Ustica is a small volcanic island (9 sq. km) around 70 km away from the northern Sicilian shores. The low altitude (and hence low visibility), the almost total lack of freshwater springs, the absence of valuable geological resources, and the remarkable distance from the north-western coast of Sicily made Ustica relatively marginal in the trade dynamics of the southern Tyrrhenian area during prehistory. Nevertheless, human occupation started at the end of the Middle Neolithic period (around 4700 BC), as attested by the recent archaeological survey of Piano dei Cardoni. These findings witness the spread of Neolithic communities in some areas of the island, that probably represented a stepping stone in the obsidian trade route and exchanges between Aeolian islands and western Sicily. Recent investigations brought to light a Neolithic site with a hypogeum stone megalithic sepulchral area. The analyses on the origin of raw materials and artifacts (obsidian, volcanic stones, pottery) and the cultural comparisons show a multiple sources reliance, based both on local and imported materials (from Aeolian islands and Sicily but also Southern Italy).

11 ROUTES ACROSS THE BASALT: ANALYSING PATHWAYS IN THE JORDANIAN DESERT TO DETERMINE PREHISTORIC MOBILITY PATTERNS

**Abstract author(s):** Smith, Stefan (Universiteit Gent)

**Abstract format:** Oral

The Harra desert of northeastern Jordan is part of a basaltic plateau that stretches from southern Syria into the northwestern corner of Saudi Arabia. While archaeological projects over the last few decades, and in particular the last few years, have identified a dense prehistoric site distribution, the important question of human movement across this region is less well investigated. This is a crucial issue in this landscape in particular due to the extreme access difficulties of traversing the dense scatter of basalt rocks that cover almost its entire surface.

The “Western Harra Survey”, co-directed by the author and M.-L. Chambrade, Archéorient, Lyon, is a project conceived to study the interior of the Harra. A comprehensive remote sensing survey and four seasons of fieldwork have, among other results, identified a complex network of paths cleared through the basalt, some extending long distances, linking sites along roughly linear trajectories over many kilometres. Others appear to emanate from individual sites towards resources, such as valleys for seasonal water. A preliminary analysis first presented at the Landscape Archaeology Conference (LAC) in 2018 showed that a majority of paths connect sites to natural access features or resources, while a minority connect sites with each other. Building upon this research, this paper will analyse various properties (e.g. width, depth, uniformity of trajectory) of a variety of paths using a combination of ground observations and remote sensing data (e.g. vectorised satellite imagery, drone-derived digital elevation models). Together, this will show which paths were in most frequent use, or re-use, and which were used less often or fell out of use relatively quickly. This can shed light on the main reasons for human mobility in the Harra desert, which regions were strongly connected with each other, and potentially identify sociocultural links across this vast landscape.

12 ANDEAN MOBILITIES IN TRANSITION: A DEEP-TIME HISTORY OF INTERACTION AND DEPENDENCY IN SOUTHERN PERU

**Abstract author(s):** Mader, Christian (University of Bonn) - Beresford-Jones, David (University of Bonn; University of Cambridge) - Lane, Kevin (University of Buenos Aires) - Cadwallader, Lauren (PLOS Cambridge) - Chauca, George (National University of San Marcos) - Isla, Johny (Peruvian Ministry of Culture) - Reindel, Markus (German Archaeological Institute)

**Abstract format:** Oral

Mobility defines human behaviour and is implicated in socioeconomic dependency and change through the movement of ideas, technologies, material culture, people and animals, entailing diverse activities such as transhumance, migration, labour, trade, pilgrimage and colonialism. In this paper we study mobility as a decisive factor in pre-Columbian social development in the Andean region by bringing together data from two large-scale archaeological studies of entire Andean watersheds, from their highland headwaters to the Pacific littoral: the German Archaeological Institute’s (DAI) Nasca-Palpa Archaeological Project and Cambridge University’s One River Project. The Andean region is the perfect theatre for an archaeology of mobility because its extreme topography compresses enormous vertical diversity across short horizontal distances, propagating a concomitant diversity of transhumant and agro-pastoralist human trajectories. By uniting archaeological findings of these two projects from the Río Grande de Nasca and Río

Ica drainages we create a credible regional perspective rare in Andean archaeology, and, moreover, essential for interpretations of mobility. We use new data from geochemical analyses of obsidian lithics, stable isotope analyses of human and camelid remains and radiocarbon dating to offer insights into the origins of mobility here through the transition from hunting and gathering to pastoralism and agriculture, and the subsequent transformations in patterns of mobility and dependency that, we argue, call new attention to the definitions of the so-called ‘horizons’ and ‘intermediate’ periods of the pre-Columbian past.

13 INTERDISCIPLINARY EVIDENCE FOR MIGRATION, MOBILITY, AND COMMUNITY FORMATIONS AFTER THE DECLINE OF THE ROMAN EMPIRE IN THE CARPATHIAN BASIN

**Abstract author(s):** Knipper, Corina (Curt Engelhorn Center Archaeometry - CEZA, Mannheim) - Koncz, István - Rácz, Zsófia (Eötvös Loránd University, Institute of Archaeological Sciences, Budapest) - Hajdu, Tamás - Szeniczey, Tamás (Eötvös Loránd University, Faculty of Science, Institute of Biology, Department of Biological Anthropology, Budapest; Hungarian Natural History Museum, Department of Anthropology, Budapest) - Ódor, János (Wosinsky Mór Museum, Szekszárd) - Mende, Balázs (Research Centre for the Humanities, Hungarian Academy of Sciences, Budapest) - Vida, Tivadar (Eötvös Loránd University, Institute of Archaeological Sciences, Budapest)

**Abstract format:** Oral

The decline of the Roman rule caused significant political instability and led to the emergence of various ‘Barbarian’ powers. Scholars proposed that this situation caused a remarkable number of people to re-settle so that the time between the end of the 4th and the 6th century AD is generally considered the “Migration Period”. Using archaeological, anthropological, and multi-isotope data from the cemeteries of Mözs in Pannonia (5th century) and Hajdúnánás in the Transtisza region (5th-6th century), we compare direct evidence for individual residential changes inside and outside of the former Roman Empire. Despite geological and climatic homogeneity of the study area in general, we find indication for a remarkable number of non-local individuals at both sites. Some of this evidence goes along with similarity in dietary habits or artificial modifications of human skulls. At both sites, non-local individuals are not restricted to the first generation of inhumations, but also include later arrivals. Moreover, they exhibit differentiation regarding age and sex as well as placement of the burials within the sites, pointing towards complex patterns of individual and group mobility in a generally unsettled time.

421 DEMOGRAPHY IN ARCHAEOLOGY BEYOND BOOM AND BUST? CRITICAL EXAMINATIONS OF PHASES OF UNDER- AND OVERPOPULATION

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Hinz, Martin (Institute for Archaeological Sciences, University of Bern; Oeschger Centre for Climate Change Research, University of Bern) - Kolář, Jan (Department of Vegetation Ecology, Institute of Botany of the Czech Academy of Sciences, Brno; Institute of Archaeology and Museology, Masaryk University, Brno) - Heitz, Caroline (Institute for Archaeological Sciences, University of Bern; Oeschger Centre for Climate Change Research, University of Bern) - Laabs, Julian (Institute of Pre- and Protohistoric Archaeology, Christian-Albrechts-Universität zu Kiel; Department of Geography, Physical Geography, Christian-Albrechts-Universität zu Kiel)

**Format:** Regular session

The study of prehistoric population dynamics has experienced a significant upswing in recent years, not only due to new methodologies but also growing significance of the human-environment relationship. However, current approaches are comparatively simple: we observe an increase or decrease in the number of archaeological finds or sites at certain times, and conclude from this population increase or decrease. Special attention is paid to so-called boom-and-bust phases, often explained by environmental disasters; above all effects of abrupt climatic deterioration. Many approaches are frequently based on a rather simple Malthusian worldview: the population grows until it reaches the limit of its environment’s carrying capacity, and then has to move into a dynamic equilibrium, determined by technological innovation as well as by birth control and/or emigration. The other extreme is a simple Boserupian perspective of ever-increasing innovation through population pressure, raising the environment’s carrying capacity by technological advancements. In this scenario, mainly external triggers (warfare, climate events, or else) would be the cause of bust phases in human demographic history. How can data-driven archaeology help to assess the most plausible scenario? Over the long course of human history, the above-mentioned model’s expectations of exponential population growth cannot be observed. To explain the prehistoric population dynamic we might search for more mundane factors keeping population sizes ‘in check’. What role do diseases and violence play? How can social norms and inter-group relations influence demographic dynamics?

For this session, we invite contributions addressing the question of how to achieve a meaningful and historically significant investigation of past demographic dynamics beyond the mere descriptive representation of increased or decreased amounts of archaeological remains. We would be happy to receive contributions with integrative and alternative models, multi-proxy evidence or simulation studies showing in which direction demographically oriented archaeology might develop in the 2020s.

1 DEMOGRAPHY IN ARCHAEOLOGY AS THE STUDY OF BOOM AND BUST PHASES? AN ASSESSMENT OF THE CURRENT STATE OF RESEARCH

**Abstract author(s):** Laabs, Julian (Institute of Pre- and Protohistoric Archaeology, Christian-Albrechts-Universität zu Kiel; Department of Geography, Physical Geography, Christian-Albrechts-Universität zu Kiel) - Hinz, Martin - Heitz, Caroline (Institute for Archaeological Sciences, University of Bern; Oeschger Centre for Climate Change Research, University of Bern) - Kolář, Jan (Department of Vegetation Ecology, Institute of Botany of the Czech Academy of Sciences, Brno; Institute of Archaeology and Museology, Masaryk University, Brno)

**Abstract format:** Oral

The question of the size, density and demographic structure of human populations has a very profound impact on how we imagine communities in prehistory and their relations within the social and natural environment. Therefore, the study of such relations has preoccupied researchers since the early years of the discipline. Particular attention has always been paid to the extreme: signs of severe population decline in particular have always called for explanation and its embedding into an overall historical narrative. Often, proposed interpretations of extreme changes in past population sizes are based on single proxies and are explained by correlated contemporaneous or preceding events in other - mostly palaeoenvironmental - proxies. Rarely, but increasingly, investigations into past demographic developments have been systematically supported by a general consideration of various indicators on different spatio-temporal scales. Therefore, it is not surprising that the popular notion of collapse was quickly voiced where societies' doom was sealed by single events or developments.

In this introduction to the session, we briefly reflect the historical background of archaeological demography and the theoretical considerations in the study of boom and bust phases to critically examine the methodological challenges on how they could be reconstructed from archaeological contexts. We also like to discuss different possible reasons (e.g. wars, invasions, diseases, climate, technological and social change, ...), their mutual influences and interrelations, as well as consequences for such potentially dramatic demographic developments labelled as boom or bust. Above all, we will present our view on how data-driven archaeology can contribute to a better understanding of such particularly prominent phases in the demographic dynamics of prehistory and make them relevant as a part of human history by means of a holistic approach and analysis.

2 FROM UNCONSTRAINED TO DENSITY-DEPENDENT GROWTH: 900 YEARS OF PUEBLO PRE/HISTORY

**Abstract author(s):** Kohler, Tim (Washington State University; Santa Fe Institute; Crow Canyon Archaeological Center) - Gillreath-Brown, Andrew - Bird, Darcy (Washington State University) - Bocinsky, R. (Montana Climate Office, University of Montana; Division of Earth and Ecosystem Sciences, Desert Research Institute; Crow Canyon Archaeological Center)

**Abstract format:** Oral

The Pueblo portions of the US Southwest underwent rapid population growth throughout the first millennium CE and up to ~1100 CE. During that time there were several increasingly large societal transformations that seem to have had causes that were jointly social and climatic in nature. These coincide with the ends of the BMIII (~700), PI (~900), and PII (~1140) periods in the standard Pecos taxonomy and in many places resulted in disaggregation of villages and changes in architecture and other technologies, spikes of violence, declines in wealth inequality, and minor population movements. The end of the PIII period, ca. 1280, was different in character and more clearly connected with external rather than social causes. Significant climatic variability limiting maize production, and the likely intrusion into the Southwest of hunter-gatherers who possibly focused their negative reciprocity on Pueblo people, were leading causal factors. The result was a real collapse, resulting in tens of thousands of people moving hundreds of kilometers to new homes to the southwest, south, and southeast areas where Pueblo people still thrive today. These movements apparently took place over several decades. In these new areas, Pueblo peoples transitioned to a low-growth demography, with lower crude birth rates and life expectancies. This migration and changed demography were connected with very significant culture change, which we review. This entire history does not cleanly correspond to either a Malthusian or a Boserupian process, though Malthusian elements are relatively prominent in the early portions of the sequence. In the same way that we have to go beyond the caricatures of cyclic processes provided by resilience theory, paleodemographic approaches in archaeology can usefully reference both Malthus and Boserup but ultimately have to take from simple models what they have to offer while ending at a real encounter with history.

3 THE LIMITS OF LATE MESOLITHIC POPULATION IN NORTHERN GERMANY – WOODLAND DENSITY AND GAME DENSITY AS BASE FOR POPULATION GROWTH

**Abstract author(s):** Doerfler, Walter (Institut fuer Ur- und Fruehgeschichte Kiel)

**Abstract format:** Oral

Late Mesolithic Hunter-gatherer-fisher communities at the Baltic coast were semi-sedentary people with a wide range of food resources. At the interstice between marine, limnic and terrestrial environments they had seasonally specific opportunities for gathering (plants, shellfish, snails and eggs) hunting (seals, birds, red deer, roe deer, wild boar, elk and many small species) and fishing. Nevertheless, these resources were not endless and had to be explored carefully for a sustainable economy. A quantitative model of the density of potential game, based on archaeological, zoo-archaeological and palaeoenvironmental data shows the potential proportion of meat for the nutrition. According to the calculations the population growth was limited by the carrying capacity at a value

of 0,11 persons per km². Whether this population density was reached and if so, what mechanisms regulated the 'dynamic equilibrium' offers space for speculation. A higher productivity of the landscape could be reached with exploitation of formerly not reachable resources. Animal husbandry and leaf foddering were the first reasons for the success and spread of the Neolithic economy.

4 ESTIMATING ABSOLUTE POPULATION NUMBERS USING BAYESIAN DEMOGRAPHIC MODELLING

**Abstract author(s):** Hinz, Martin - Heitz, Caroline (Institute for Archaeological Sciences, University of Bern; Oeschger Centre for Climate Change Research, University of Bern) - Kolář, Jan (Department of Vegetation Ecology, Institute of Botany of the Czech Academy of Sciences, Brno; Institute of Archaeology and Museology, Masaryk University, Brno)

**Abstract format:** Oral

One of the greatest challenges for estimating population numbers and densities in prehistory is to properly take into account the nature, potentials and challenges of the archaeological record. We have only very thin and heterogeneous indicators at our disposal, which are poorly understood in their relationship to the parameter to be measured and their internal error. Concentrating on only one of the possible indicators, for example sum calibration of a large number of radiocarbon dates, means that there is a great danger of interpreting the ups and downs of the curve directly as boom and bust phases. But how can different indicators be meaningfully related to each other in order to mutually validate and substantiate the individual significance? How can the uncertainty of the individual indicators be estimated in order to check whether phases of increased or decreased settlement activity are actually evident? Finally, how can we arrive at absolute figures to interpret these demographic dynamics in prehistoric societies?

For us, Bayesian statistics seems to be a well-established way to address these challenges. In this talk, we will present our approach of using a simple Bayesian model to combine a wide range of indicators to arrive at estimates of absolute population trends that, on the one hand, do justice to the source data and their uncertainties and contradictions, and, on the other hand, provide a robust basis for further interpretations about the nature of boom and bust phases and the significance of long- and short-term demographic trends. We believe that the method, which has revolutionised the evaluation of radiocarbon dating over the past 20 years and has put quantitative evaluations and predictions on a completely new footing throughout the scientific world, represents an enormously promising approach to one of the most pressing questions in prehistoric archaeology.

5 PREHISTORIC DEMOGRAPHY OF CENTRAL EUROPE IN A MULTI-PROXY PERSPECTIVE. WHICH PROXY IS THE BEST FOR STUDYING THE BOOMS AND BUSTS?

**Abstract author(s):** Kolar, Jan (Institute of Botany of the Czech Academy of Sciences; Institute of Archaeology and Museology, Masaryk University) - Macek, Martin (Institute of Botany of the Czech Academy of Sciences) - Abraham, Vojtěch (Institute of Botany of the Czech Academy of Sciences; Charles university) - Tkáč, Peter (Institute of Botany of the Czech Academy of Sciences)

**Abstract format:** Oral

Archaeology nowadays works with several demographic proxies providing us with absolute or relative numbers of the population in past. Nevertheless, with all the current advances in the theory behind, in computational methods and capacities and emerging large-scale datasets, these estimations can still be tricky. We can calculate our models of population dynamics based on number of sites, summed probability distributions of radiocarbon dates or number, age structure of the excavated deceased or even area of inhabited houses. How do the estimations from different proxies differ? And how do we decide which should we use? Are some of them regionally or chronologically specific or can all the proxies be used universally? Are some of them biased by social transformations in the past? Or by history of archaeology in general? This paper will explore these questions within a multi-proxy study covering the area of Czech Republic and will discuss the results from a long-term perspective.

427 ISLAND SUSTAINABILITY AND RESILIENCE IN EUROPE: ARCHAEOLOGICAL, PALAEOECOLOGICAL AND HISTORICAL APPROACHES

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Brown, Antony (Tromsø Museum, Arctic University of Norway) - Downes, Jane (University of the Highlands and Islands, Archaeology Institute) - Wickler, Stephen (Tromsø Museum, Arctic University of Norway) - Martinsson-Wallin, Helene (Department of Archaeology and Ancient History, Uppsala University, Campus Gotland)

**Format:** Regular session

Islands present archaeologists and historians with an unrivalled opportunity to study the sustainability and resilience of complex socioecological systems. This is facilitated by their semi-permeable boundaries and their often high degrees of self-sufficiency in basic subsistence terms. In many cases their relationship to a motherland or mainland is also critical, and sometimes recorded, and it can be argued that in some cases, especially on inland lakes, islands can be 'central places' (Bäck 1997). But do they inherently lack socioecological resilience (Petzold 2017) or is this contextual and fluid, and if so what are the critical factors. This is highly relevant to the problem of sustaining small island communities faced by many European countries today. Archaeological, palaeoecological and historical evidence can all be brought to bear on this problem. This session will examine these question with particular attention to small-medium sized European islands and archipelagos using evidence ranging from archaeological excavation though palaeo-environmental studies to the use of documentary sources. A range of methodologies is highly appropriate due to the mixed marine-land economies and variable dependency on importation both in time and space. Papers exploring the potential

of new techniques will be encouraged including traditional proxies, biomarkers, aDNA, remote sensing, geoarchaeology, and novel dating methods. As well as particular opportunities island also present a range of challenges from a lack of suitable sites to a lack of administrative identity. The identification of critical factors in the trajectories of population and well-being on islands is highly relevant to present policies which grapple with how relatively small populations can be maintained in the face of both ecological and equity considerations. This session will present a variety of studies from different areas of Europe addressing these themes and highlighting the importance of island archaeologies.

ABSTRACTS:

1 ISLAND-RESILIENCE-IN-THE-FACE-OF-VIKING-RAIDS-AND-POLITICAL-RESTRUCTURING-DURING-THE-1ST-MILLENNIUM-AD: COMBINING-ARCHAEOLOGICAL,-HISTORICAL-AND-PALAEOECOLOGICAL-APPROACHES-TO-BETTER-UNDERSTAND-SOCIAL-TRANSFORMATIONS-ON-THE-ISLAND-OF-IONA

**Abstract author(s):** Jones, Samantha (University of Aberdeen) - Allison, Enid (Canterbury Archaeological Trust) - Campbell, Ewan (University of Glasgow) - Evans, Nick - Mighall, Tim - Noble, Gordon (University of Aberdeen)

**Abstract format:** Oral

This paper examines the early monastic site on the island of Iona, which was founded following the arrival of St. Columba in AD 563. For over 200 years the monastic site was one of peace and prosperity. It became a renowned centre of learning and the spread of Celtic Christianity throughout many parts of Scotland and northern England. During this period Iona was also a focus of culture, legal knowledge, literature, art, and learning. Important works were produced in Latin and Gaelic, ranging from poetry to chronicles, saints' lives, legal texts and perhaps the lavishly decorated gospel book known as the Book of Kells. However, crisis struck the island from the AD 790s, when a series of Viking attacks over a thirty-year period had a potentially devastating impact on the monastic community and from about AD 800–1100 the western seaboard and isles of Scotland were settled and conquered by Scandinavians. While the documentary sources provide some evidence for the history of Iona, especially across the period from AD 563–740, the socio-environmental impacts of Viking attacks on Iona and other ecclesiastical and political upheavals between the 8th–13th centuries were unclear. Here we present the results from integrated historical, archaeological and palaeoenvironmental analyses (pollen, non-pollen palynomorphs and beetles) of sediments extracted adjacent to and from recent archaeological excavations of the monastic banks and ditch to fill in some of the gaps in knowledge regarding early monastic settlement and the socioenvironmental impacts of Viking raids and Scandinavian Influence.

2 THE NATURE AND DISTRIBUTION OF DEEPENED RIGGED AGRICULTURAL LANDSCAPES WITHIN LOCH/ LOUGH CATCHMENTS ACROSS ISLANDS IN THE SEA OF MOYLE

**Abstract author(s):** Pears, Ben (University of Southampton) - Brown, Antony (Tromsø Museum, UiT, Tromsø, Norway; University of Southampton) - Fonville, Thierry (University of Southampton)

**Abstract format:** Oral

Deepened 'rigged' soils across islands provide essential information as to the nature and extent of historical agriculture and land use. Such deposits have been readily identified across the globe including mainland Europe, Ireland and the northern extremities of the UK (Orkney, Shetland and Outer Hebrides). However, very little research has been conducted upon the Inner Hebrides and the Sea of Moyle between Scotland and Ireland and comparisons in this area can greatly improve the understanding of loch/lough catchment land use history, soil development and erosion and inter-island connectivity.

Soil and sediment sampling across four islands in the Sea of Moyle (Islay, Colonsay, Lismore and Rathlin) have demonstrated distinctive areas of deepened agricultural soils across rigged fields associated with former settlement. In each case these sequences are more extensive than areas of 'natural' uncultivated land and demonstrate distinctive horizonation and sedimentological evidence of inorganic and organic additions.

The soil sequences from each catchment are also analysed against loch/lough sediment sequences and the increasing presence of distinctive coarse texture horizons are likely to be indicators of phases of enhanced landscape clearance, agricultural activity and sediment erosion from terrestrial to lacustrine source ultimately through the intensification of the rigged arable process.

3 RECONSTRUCTING POPULATION DYNAMICS USING FAECAL LIPID BIOMARKERS TO CHARACTERISE WAVES OF COLONIZATION IN THE SEA OF MOYLE

**Abstract author(s):** Mackay, Helen (Durham University; Newcastle University) - Henderson, Andrew (Newcastle University) - Fonville, Thierry - Pears, Ben (University of Southampton) - van Hardenbroek, Maarten (Newcastle University) - Plunkett, Gill - Gleeson, Paddy (Queen's University Belfast) - Alsos, Inger (Tromsø Museum, Arctic University of Norway) - Brown, Tony (Tromsø Museum, Arctic University of Norway; University of Southampton)

**Abstract format:** Oral

The Sea of Moyle (Sruth na Maolie), located between Northern Ireland and Scotland, contains a group of small islands that have experienced multiple waves of colonization and population change over the prehistoric, Medieval and Post-Medieval periods. Whilst many of these islands have comparable colonization histories and archaeologies, their physical geographical characteristics differ.

For example, Islay and Colonsay are separated by <10 km of water, but their size varies by an order of magnitude and Islay soils are considered more fertile. These islands present an excellent case study to examine long-term relationships between landscapes and population dynamics, and assess the extent to which they contribute to island socioecological resilience.

Our research aims to test whether faecal lipid biomarkers, extracted from lake sediments, can be used to reconstruct the presence of humans and domesticated animals over the last 1500 years; this would extend the record of population histories in island communities beyond written documents. Faecal steroid biomarkers have been detected in lake sediments from Loch Finlaggan (Islay) and Loch Fada (Colonsay) covering the last 1500 years. Ratios of faecal steroid compounds indicate a temporal difference in the presence of humans and use of animals in the lakes' catchment. The ability of steroids to provide evidence of population change is demonstrated by comparisons with historical population records, archaeological evidence and other proxies of anthropogenic-induced nutrient changes (e.g. diatom-inferred phosphorus and biogenic silica) characterised from the lake cores. Our lacustrine data highlight differences in the persistence of human occupancy between the lake catchments, which correspond with settlement changes during the Viking and Medieval periods. This application of lacustrine faecal steroid analyses extends understandings of population dynamics on the islands of Islay and Colonsay, but also highlights key steroid taphonomy questions, which must be explored before quantitative population reconstructions can be obtained using this approach.

4 HUMAN-ENVIRONMENT DYNAMICS AND MARITIME IDENTITIES IN ARCTIC NORWAY'S SEA OF ISLANDS SINCE THE IRON AGE

**Abstract author(s):** Wickler, Stephen Kent (The Arctic University Museum of Norway, UiT The Arctic University of Norway)

**Abstract format:** Oral

Marine resources have always been critical for sustaining coastal settlement in northern Norway where a myriad of islands provide essential nodes in a complex web of maritime interaction and interdependence. Ongoing integrated archaeological and paleoenvironmental investigations in the Lofoten archipelago reveal the impact of climate changes on marginal agricultural environments and relative sea-level variations on maritime communities (harbor access, site distribution) during the Iron Age (500 BC – AD 1050). Recent maritime archaeological projects have demonstrated the central importance of small to medium sized offshore islands since the Viking Age (AD 800-1050) in maintaining an islander identity dependent on marine resources and proximity to fishing grounds. Although these islands may appear inhospitable, barren, and remote to the modern-day population, they were the focus of intensive fishing related settlement characterized by seaborne connectivity rather than insularity into the 20th century. The material expressions of an islander perspective are critically examined and assessed within a dynamic framework of expanding networks of interaction and exchange from the Iron Age through the Early Modern Period. This includes recently analyzed boat remains from offshore island bogs providing the earliest evidence for plank-built boats and rowing in Scandinavia at the transition from the Bronze Age to Pre-Roman Iron Age. The depopulation of numerous once intensively occupied offshore islands since the 1940s underscores the dramatic transformation of island-based socioecological systems from centrality to marginality.

5 'A CHALLENGING ENVIRONMENT': SOILS AND LAND USE HISTORY ON TORY ISLAND/OILEÁN THORAÍ, CO. DONEGAL

**Abstract author(s):** Brown, Antony (University of Southampton; Arctic University of Norway, Tromsø) - Pears, Ben (University of Southampton) - Gleeson, Patrick (Queens University Belfast) - Ice, Brendon (Digventures Ltd.)

**Abstract format:** Oral

This paper examines the enigmatic Tory Island, 14 km off the north coast of Co Donegal. Combining archaeological, historical and palaeoecological analyses, it will explore the island's development during the later Holocene. In 1937, R.L. Praeger remarked that Tory was "The most remote and exposed of the Irish Islands...it is utterly windswept... it is strange to find that such a desolate place has been so long inhabited". Its population of nearly 300 gave a density of over 80 persons per km<sup>2</sup> in 1937 CE, making Tory the most densely populated island around the Sea of Moyle (north coast of Ireland). By contrast with this intensity of human occupation, Tory has an unusual climate: mild with rare frost and little sunshine but a high level of precipitation (1076 mm) with rain falling on average on 226 days per year. Additionally and most importantly the mean monthly windspeed is 15.6 knots and on average Tory Island has 65 days per year with gales. Given the small size of the island and the westerly prevailing wind direction this means that most of the rainfall is salt-laden. Very little archaeological work has been done on the island but it has Bronze Age field systems, two Iron Age hill forts and was an early ecclesiastical site. It is also known for the late survival of the Rundale tenure system. This paper uses a combination of soil patterns, history and archaeology, together with the first pollen analysis to better understand the environment, ecological impact and resource base of the inhabitants during. A particular focus is the transition from the later Iron Age, with a medieval ecclesiastical settlement, was established down to the present day. During this period, the landscape was drastically altered, and the island underwent considerable change.

6 **DNA EVIDENCE IN LAKE SEDIMENTS USED TO RECONSTRUCT LONG TERM LAND USE CHANGES ON SCOTTISH ISLANDS**

**Abstract author(s):** Fonville, Thierry - Pears, Ben (University of Southampton) - Alsos, Inger (Tromsø Museum, Arctic University of Norway) - Mackay, Helen (Durham University) - van Hardenbroek van Ammerstol, Maarten - Henderson, Andrew (Newcastle University) - Plunkett, Gill - Gleeson, Patrick (Queen’s University Belfast) - Brown, Antony (University of Southampton; Tromsø Museum, Arctic University of Norway)

**Abstract format:** Oral

Sedimentary ancient DNA (sedaDNA) is the analysis of DNA fragments archived within sediments. By sequencing chloroplast DNA fragments and comparing these to databases of known plant DNA sequences, it is possible to reconstruct long term vegetation patterns. In combination with radiocarbon dating and more traditional palaeoenvironmental techniques such as geochemical, pollen and diatom analysis we are able to reconstruct past land use changes, such as the creation of meadows or crop cultivation. By applying these techniques to island lake sediments we can disentangle how land use has changed over time due to population dynamics and socio-cultural factors.

The Sea of Moyle (Sruth na Maoile) project looks at the historical and socioecological resilience of island communities around the narrow sea between Scotland and Northern Ireland. Although ownership has changed since The Kingdom of the Isles centuries ago, the islands are still closely inter-connected, not least because they are within sight of each other. These islands provide a unique opportunity to reconstruct cultural and ecological change over long periods of time, due to their well-defined boundaries and their importance in cultural exchanges between the islands of Ireland and Britain.

Loch Finlaggan on the Isle of Islay is a medium sized lake, which reveals an extensive occupation history in lake sediment cores, with evidence of prehistoric crannogs, medieval and later royal and ecclesiastical occupation. Plant community shifts over time have been sequenced from the sedaDNA records, tracking many of these settlement phases into modern times, where surrounding farmsteads currently lie abandoned. The evidence from Finlaggan and other sites can be compared to other records such as census and historical data to track long term environmental change and the impact of population dynamics on the landscape.

7 **LATE-HOLOCENE ANTHROPOGENIC DISTURBANCE ON ISLAY, INNER HEBRIDES: A PALYNOLOGICAL RECORD FROM LOCH FINLAGGAN**

**Abstract author(s):** Ellis, Natalie (Newcastle University) - Pears, Ben (University of Southampton) - van Hardenbroek, Maarten (Newcastle University) - Henderson, Andrew (Newcastle University) - Scaife, Robert (University of Southampton) - Langdon, Catherine - Fonville, Thierry - Brown, Tony (University of Southampton)

**Abstract format:** Oral

We present palynological and geochemical evidence for anthropogenic impact in Loch Finlaggan. Data are derived from a lake sediment core collected adjacent to the archaeological site of Finlaggan on Islay. Archaeological evidence suggests occupation of Islay between 1200-1400 AD during Eilean na Comhairle, the Lordship of the Isles. We compare a core collected in the central part of the lake with a core taken directly adjacent to Finlaggan. Comparing these records allows interpretation of the causes, the degree of local and regional human impact and additionally determines the periods in which anthropogenic activity peaked. Results from the central core show a post-glacial sequence with an initial increase of arboreal pollen, followed by its decline due to forest clearance and grazing (Poaceae and Plantago lanceolata) in the upper part of the record. This is supported by a simultaneous increase in charcoal particles and two peaks in Ti, K and Zr, suggesting higher mineral particle input from erosion/run-off or groundwork/building activity. This pattern is even clearer in the core taken adjacent to the archaeological site, which spans a shorter time period and likely includes both the Viking and Medieval periods. This near-site core also contains two peaks in Ti, K and Zr indicating erosion/building. In this core, both peaks are accompanied by higher charcoal counts and further evidence of anthropogenic disturbance is inferred through the presence of Cerelia pollen, indicative of more intensive use of the landscape. This study enriches the archaeological evidence on Islay, providing further context to other proxy-evidence for on-site activity (e.g. sedimentary DNA and faecal biomarkers) as well as human impacts on the local and regional environment.

8 **LANDSCAPES OF CHANGE: ARCHAEOLOGIES OF HISTORIC PERIOD CHANGE ON THE ISLAND OF ROUSAY, ORKNEY**

**Abstract author(s):** Harland, Jennifer - Mainland, Ingrid - Gibbon, Sarah Jane (University of the Highlands and Islands)

**Abstract format:** Oral

The settlement of Skail, Westness, Rousay, inhabited from the Norse period to the 19th century, has seen considerable socio-cultural and climatic change during its occupation. Recent multi-faceted archaeological investigations into long term occupation and change are revealing complex buildings, rich artefact assemblages, significant environmental evidence, and unpublished archival records.

This paper will use Skail as a case study to examine sustainability and resilience in a small island context by using archaeological, palaeoecological, and historical evidence to explore oscillating powers relationship of ownership alongside self-sufficiency of occupiers of a shoreside farm. Fishing and agricultural production played a key role in the economies of the Scottish isles over our thousand year occupation sequence, but the relationships between people and the land and the sea changed dramatically during

this time. We'll be examining how local dietary customs change orientation, from a Scandinavian focus in the Norse period, towards an increasing orientation towards mainland Scotland by the early modern period.

This presentation will discuss our unpublished findings alongside our methodological approach, developed and implemented to undertake this archaeology-led community-based investigation of long term environmental and landscape change.

9 **LINDISFARNE – ISLAND IN THE STREAM**

**Abstract author(s):** Wilkins, Brendon (DigVentures; University of Leicester) - Petts, David - Kahlenberg, Raphael (Dept. of Archaeology, Durham University)

**Abstract format:** Oral

Lindisfarne is a small tidal island off the coast of NE England. It is most celebrated as a major early medieval ecclesiastical centre (c.AD630-875), and is particularly associated as the site of the creation of the elaborate 8th century Lindisfarne Gospels. The early Northumbrian church seems to have had a particular affinity with coastal and island sites – and Lindisfarne is just one of a series of early monastic sites in such locations. Such insular locations have often been framed in terms of isolation and separation, and fitted into a narrative of early monasticism being situated in remote or deserted locations. In this short paper, based on on-going research, we aim to reframe our understanding of the site, as a nodal point within a complex web of ecological and human relationships at a variety of scales, ranging from evidence of exploitation of the island's own terrestrial resources, its wider maritime hinterland and the national and international context of exchange and communication within a vibrant social, political and religious world that spans the North Sea.

10 **MAKING VISIBLE THE INVISIBLE. THE ROLE OF GEOARCHAEOLOGY TO RECONSTRUCT PAST HUMAN-ENVIRONMENT INTERACTIONS IN MEDITERRANEAN ISLANDS**

**Abstract author(s):** Revelles, Jordi (Institut Català de Paleoeecologia Humana i Evolució Social - IPHES-CERCA / Universitat Rovira i Virgili) - Ghilardi, Matthieu (CEREGE, CNRS UMR 7330, Aix-Marseille University, IRD, Collège de France, INRAE)

**Abstract format:** Oral

Changes in the archaeological record are used to assess the chronology and continuity of human occupation at different scales, suggesting the succession of phases of higher/lower demographic density or settlement intensity, the abandonment of sites or, even, the depopulation of certain areas. However, sometimes these changes are affected by taphonomic issues, changes in mobility patterns or lack of radiocarbon dates in old excavations. In addition, bioarchaeological data is limited in regions where most part of sites were excavated long time ago, causing a methodological bias and confirming that past human settlement dynamics and economic activities cannot be described based exclusively on the in-site archaeological data. The geoarchaeological research emerges as the ideal source to fill these gaps. The application of palaeobiological studies in natural deposits allows reconstructing past human-environment interactions, shedding new light for evidence of farming activities and redefine archaeological territories and human occupation temporalities.

In that context, coastal wetlands in Mediterranean Islands provide the opportunity to reconstruct the palaeoenvironmental evolution and evidence of human impact, especially since the adoption of farming activities during the Neolithic. In this work we show the reconstruction of Middle and Late Holocene socio-environmental history in Corsica, providing a detailed history on the impact of farming activities (agriculture and husbandry) in coastal wetlands based on pollen records from different wetland areas along the Island. The evidence of the impact of farming activities on the landscape in Corsica is attested since Neolithic (ca. 7400 cal BP) and increased exponentially from the Iron Age onwards. Finally, this study shows the importance of wetland areas preservation in Mediterranean Islands, not only by the ecosystem services they provide, also for their value as a historical record of past human-environment interactions.

11 **DELOS, A SMALL ROCK ISLAND: THE RELATIONS BETWEEN THE ESTABLISHMENT OF THE PAN-HELLENIC SANCTUARY AND THE USE OF NATURAL RESOURCES**

**Abstract author(s):** Angliker, Erica (University of London, Institute of Classical Studies, Research Associate)

**Abstract format:** Oral

The island of Delos became famous in Antiquity despite its small size because it housed one of the most important and busiest sanctuaries in the Aegean. Scholars have spent much time debating the political disputes over Delos and the development of the sanctuary. This paper, by contrast, considers the establishment of the major Pan-Hellenic sanctuary on Delos by focusing on the uses made of the island's natural resources. It begins by discussing the strategic geographic location of Delos in the middle of the Aegean between Asia Minor and Mainland Greece, which make it a suitable nodal point for those crossing the Aegean. It then looks at the relation between the major sanctuary's growth and the exploitation of natural resources such as the island's plenteous store of fresh water and its large natural harbour that enabled it to accommodate many ships. Finally, the paper discusses Delos's agricultural use of the land of the neighbouring island of Rhenium, thereby showing how the survival and subsistence of a small island like Delos was possible thanks to the natural resources of a neighbouring island.

TRANSPORTED LANDSCAPES AND SOCIAL RESILIENCE IN THE BALEARIC ISLANDS SINCE PREHISTORY. THE STUDY-CASE OF SANTA PONÇA (MALLORCA, WESTERN MEDITERRANEAN)

**Abstract author(s):** Servera-Vives, Gabriel (Laboratorio di Palinologia e Paleobotanica. Dipartimento di Scienze della Vita. Università degli Studi di Modena e Reggio Emilia; ArqueoUIB, Departament de Ciències Històriques i Teoria de les Arts, Universitat de les Illes Balears) - Snitker, Grant (Department of Crop and Soil Sciences, College of Agricultural and Environmental Sciences. University of Georgia) - Gómez-Pujol, Lluís (Earth Sciences Research Group, Dept. of Biology. University of the Balearic Islands) - Picornell-Gelabert, Llorenç (ArqueoUIB, Departament de Ciències Històriques i Teoria de les Arts, Universitat de les Illes Balears) - Fornós, Joan J. (Earth Sciences Research Group, Dept. of Biology. University of the Balearic Islands) - Florenzano, Assunta (Laboratorio di Palinologia e Paleobotanica. Dipartimento di Scienze della Vita. Università degli Studi di Modena e Reggio Emilia) - Calvo Trias, Manuel (ArqueoUIB, Departament de Ciències Històriques i Teoria de les Arts, Universitat de les Illes Balears) - Mercuri, Anna Maria (Laboratorio di Palinologia e Paleobotanica. Dipartimento di Scienze della Vita. Università degli Studi di Modena e Reggio Emilia)

**Abstract format:** Oral

Islands are fragile environments that may throw light on long-term cultural and environmental dynamics by amplifying geographical and cultural factors. The Balearic Islands are crucial for the study of these interactions during the Holocene due to their presumably late human colonisation at ca. 2500-2300 BC, compared to other Mediterranean islands. The EU-funded OLEA-project (G.A.-895735) aims to focus on the drivers and timing of the spread of Olea macchia as a central feature of the current Balearic mosaic landscape. This work will try to move forward the research on mosaic landscape formation in the Mediterranean in relation to human, climate, and environmental drivers. This research also benefits from the research project Mobility and connectivity of prehistoric communities in the Western Mediterranean during the Late Prehistory (University of the Balearic Islands, PID2019-108692GB-I00; and CGL2016-79246-P -AEI-FEDER, UE-), which addresses a diachronic analysis of mobility and connectivity of prehistoric communities in the Balearic archipelago.

To do so, we will present the results of the paleoenvironmental study of the coastal lagoon sequence of Santa Ponça. This area is rich in archaeological sites ranging from the Bronze Age to Modern Times, so providing a record of landscape transformation associated with cultural changes. We will combine off-site paleoenvironmental data (pollen, non-pollen palynomorphs, sedimentology, sedimentary charcoal) and on-site archaeobotanical and archaeological data, to understand socioenvironmental interactions, how newcomers produced new types of landscapes and how humans faced societal and climate challenges throughout history. Also, new indicators for the Balearic landscape and human activities will be based on modern pollen and NPPs to further precise the causality and intensity of landscape changes.

ASSESSING HUMAN DIET AND FOOD PROCESSING THROUGH ORAL HEALTH AND STABLE ISOTOPES DURING THE COLONIAL PERIOD IN GRAN CANARIA

**Abstract author(s):** Morquecho Izquier, Aarón - Brito-Mayor, Aitor - Santana Cabrera, Jonathan (G.I. Tarha. Department of Historical Sciences. University of Las Palmas de Gran Canaria)

**Abstract format:** Oral

The Canary Islands were conquest and colonised by the Kingdom of Castile at the end of the 15th century AD. These islands were previously inhabited by farming Indigenous people that arrived around the 2nd century AD from North Africa. The Canarian colonial economy combined European and indigenous subsistence strategies. Europeans brought to the islands their domestic plants and animals and adapted their technological skills to these island environments. Moreover, they introduced new food processing techniques and food habits different from the indigenous period. This study presents a comprehensive analysis of oral health and stable isotopes from seven colonial sites in Gran Canaria Island (n= 120 individuals), to illustrate the potential contribution of bioarchaeology to understanding the human diet and food processing changes in the Spanish colonial experience in the Canary Islands. The results of our study, interpreted jointly with historical records and archaeological evidence, suggest that colonial dietary habits did not significantly differ from the indigenous period. However, these results highlight the introduction of new food resources and food processing techniques. This pattern reflects reliance on local resources and indigenous subsistence strategies, despite historical evidence of a new agricultural economy. Our study provides a new perspective on colonial life in the Canary Islands and human adaptation to oceanic islands.

FIRST STAGE ABROAD: NEW INSIGHTS INTO THE ANIMAL HUSBANDRY OF THE SPANISH COLONIAL PERIOD FROM SAN MARTIN (GRAN CANARIA)

**Abstract author(s):** Brito-Mayor, Aitor - Morquecho-Izquier, Aarón (G.I. Tarha. Department of Historical Sciences. University of Las Palmas de Gran Canaria) - Moreno-Benítez, Marco (Tibicena, Arqueología y Patrimonio) - Santana-Cabrera, Jonathan (G.I. Tarha. Department of Historical Sciences. University of Las Palmas de Gran Canaria)

**Abstract format:** Oral

The Canary Islands were inhabited by farming Indigenous people that arrived around the 2nd century AD from North Africa. They were conquest and colonised by Castilian people at the end of the 15th century AD. These islands played a significant role in the European expansion in the Atlantic as they were in the maritime routes between Europe and America during the Early Modern period. European colonisers translocated Old World animals into the Canary Islands and made use of indigenous livestock, yielding a new pattern of

animal husbandry. This study presents the first zooarchaeological analysis of the Spanish colonial period of the Canary Islands using the zooarchaeological assemblage of the historical hospital of San Martín. This facility is in Las Palmas de Gran Canaria city (Gran Canaria Island) and dates from the early 16th to late 17th centuries. Zooarchaeological data and stable isotope analysis were used to investigate animal translocation and animal husbandry practices. Historical, archaeological, and zooarchaeological evidence provide a glimpse of the human-animal interactions in the first stages of the European colonial experience in the Atlantic world.

CORSICA BETWEEN LAND AND SEA: ENVIRONMENTAL RESOURCES AND PRODUCING DYNAMICS

**Abstract author(s):** Piccardi, Eliana (Independent researcher)

**Abstract format:** Poster

Corsica island is not a small sized European island; nevertheless, it may offer multifold patterns about the environmental resources use and their inside or external management involving, somehow, sustainability and trade issues during Iron Age and the Roman Period.

The rare literary sources and the past investigations without modern scientific analyses have long time affected the reconstruction of the ancient landscape and of the exploiting frame; nevertheless, in the last years, modern system of analysis have begun to be employed about the island evidence belonging to this chronological arch: some examples may be given.

The Late Iron Age glass artifacts named as ‘anneaux porcelaniques’ in the archaeological literature were probably locally made, although the arrival of the rough material itself to the island postulate interesting external connections. About the use of land resources we still have scattered evidence of the last millennium BC before the Roman period (e.g. Tavera) and an increasing horizon of older and new evidence about the Roman Period (e.g. in the Early Empire rural site around Mariana). Besides, the mention of some war redemption due to the Romans shows silvo-agro-pastoral materials exploited on the island, like wax and pitch.

The evidence likely related to sea-resources, beyond short mentions for the Roman Period in the written documents, is still to be explored by the archaeometric methods in its whole, and it is mostly related to ancient and nowadays coastal lagoons landscape: e.g. at Cala, at M. Bughjo feet, in the surroundings of Mariana, in the pond of Diana nearby Aleria. Here, a small island has been created by shell layers due to the continued exploitation since antiquity and in some Etruscan tombs were found shells and glass beads, while old oral sources refer about the finding of fishes inside of containers or fountains in the Roman site.

ADULT AGE-AT-DEATH IN PAST POPULATIONS: WIDENING HORIZONS OF METHODS, APPROACHES AND INTERPRETATIONS

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Fuchs, Katharina - Müller-Scheessel, Nils - Rinne, Christoph (Kiel University) - Séguy, Isabelle (French Institute for Demographic Studies)

**Format:** Regular session

After experiencing childhood and adolescence a person goes through different stages of life in adulthood, defining their roles in respective social, biological and economic systems. Fertility and reproduction, acquired life experience and skills or physical impairments caused by age and illness strongly influence these roles, and vice versa. Adulthood is thus a key aspect for understanding the life of past societies and of special significance for research on palaeodemography, social archaeology, palaeopathology or palaeoepidemiology. However, we all face the same problem: estimations of adult age-at-death are inaccurate. Due to the osteological reality (skeletal preservation, age marker specificity, reference collections), the information we deal with are often wide-spanning age ranges, hampering supraregional and diachronic population studies. Furthermore, recent research suggests that osteological methods that have been used for decades determine ‘the young too old, and the old too young’, implying shifts in mortality structures. These shifts cause discrepancies in life expectancy across different cultural and socioeconomic backgrounds. The consequences of these discrepancies for past, present and future research are poorly understood. Thus, central aims of this session are to:

- discuss innovative disciplinary and interdisciplinary methods for determining or calibrating adult age-at-death in order to improve the accuracy,
- examine potential shifts in mortality with respect to analytical approaches and interpretation,
- challenge and diversify the concept of ‘adulthood’ in its biological social, and economic meaning,
- explore synergies between experts from different disciplines to raise the discussion on this complex and significant topic to a new level.

We welcome theoretical and applied contributions, including methodological, qualitative and/or quantitative studies on ancient populations across time and space. We invite a broad scientific audience from the fields of biological, forensic and archaeological anthropology, palaeopathology, prehistoric and historical archaeology as well as those interested in aDNA research and other disciplines.

ABSTRACTS:

1 ADULT AGE-AT-DEATH ESTIMATION ACCURACY – WHAT IS THE ISSUE?

**Abstract author(s):** Fuchs, Katharina (Kiel University, Institute of Clinical Molecular Biology)

**Abstract format:** Oral

In the study of past societies, determination of the biological age-at-death of skeletonized individuals is the starting point for further investigations, such as paleodemographic processes, associations between age and disease, osteobiographies and personhood, as well as individual and collective sociocultural and socioeconomic developments. Thus, the existing methodological inaccuracies in estimating adult age, the large variability in age classifications, and the resulting application of age-at-death classes for adults are problematic. Moreover, the definition of ‘age’ in the term age-at-death depends on the perspective described by chronological, biological and social age constructs which are not necessarily consistent within or between populations.

This paper is intended for the opening of the session as it briefly reviews the history of research on adult age-at-death estimations and interpretations in diverse fields of bioarchaeological research. It focuses on the efforts undertaken to overcome the discrepancies between different definitions of age and ageing. Issues such as ‘The Grandmother hypothesis’ and ‘The invisible elderly’ will exemplarily be discussed regarding their significance for studies of past populations. The paper also discusses the issue of shifts in mortality structures of adult cohorts and the implications given for paleodemography that might be expected when re-evaluating existent estimations.

The presentation illustrates why this topic must continue to play an important role in the study of past societies and which avenues should be explored for further developments.

2 ADULT AGE-AT-DEATH IN THE WINTHIR REFERENCE COLLECTION MUNICH – EVALUATION OF CURRENT ANTHROPOLOGICAL METHODS

**Abstract author(s):** Trautmann, Bernd - von Heyking, Kristin - Lee, Janette - Schratzenstaller, Barbara (The Bavarian Natural History Collections - SNSB, State Collection for Anthropology and Paleoanatomy Munich - SAPM) - Degenhart, Simon - Paulus, Christof (Ludwig-Maximilians-University Munich - LMU) - Harbeck, Michaela (The Bavarian Natural History Collections - SNSB, State Collection for Anthropology and Paleoanatomy Munich - SAPM)

**Abstract format:** Oral

The determination of age-at-death of adult individuals is still a challenging field within physical anthropology as well as forensic studies. New methods have been established for the last couple of years that make these age-at-death determination more precise. However, most of these methods are laboratory approaches that are still complex and expensive. In physical anthropology the main methods still base on macroscopic identification of features on dry bone that are quick and easy however more imprecise. The newly established Winthir collection housed at the State Collection of Anthropology and Paleoanatomy in Munich offers the possibility for evaluation and further development of these methods. This collection consists of 248 individuals (94 subadults, 154 adults) of known sex, age-at-death, occupation as well as a great amount of other personal information about every single individual. All of these people were buried in the period of 1883 to 1904. A multidisciplinary project started in February 2020 has the goal to establish this collection as a reference series that is accessible to the research community in the future. In a first step, every individual was evaluated anthropologically for sex, age-at-death, paleopathology and other visible skeletal changes with established methods without knowledge of the historical data. In further work steps we included the historic data derived from ecclesiastical and municipal sources (parish registers, civil registers, municipal registration records ecc.) to correlate it with age-specific changes in the human skeletal material and check the used methods for accuracy and handling to evaluate their usability for future anthropological work. The evaluated methods include changes in the facies symphysialis and auricularis of the pelvis and the obliteration of cranial sutures. First results show, that in general, difficulties arise especially with older individuals. But also younger women of the Winthir collection are regularly overestimated in age with osteological methods.

3 AS OLD AS YOU’RE TOLD. BIOARCHEOLOGICAL APPROACH TO AGE-AT-DEATH AND AGE CLASSES. A CASE STUDY FROM TAYMA, NORTHWEST ARABIA

**Abstract author(s):** Petiti, Emmanuele (DAI - Deutsches Archäologisches Institut)

**Abstract format:** Oral

Although the bioarchaeology of sex and gender has been a leading research avenue in the last 25 years, the “bioarchaeology of adulthood” remains a still poorly trodden path and the main interpretative models for the cultural meaning of age classes are hardly critically approached, ultimately determining conservative choices also for the methodologies of assessment of the age at death. The case presented here aims to challenge such models and outlines a direct link between new interpretation models for age classes and more focused methodological choices.

Our contribution presents the results of the bioarchaeological analyses on the human remains from a burial ground in the oasis of Tayma, Northwest Arabia (DFG project no. 63608405), which had its main occupation phase in the 4th and 3rd centuries BCE. The bone specimens, belonging to 63 individuals, mostly from single burials, were poorly preserved, presenting challenging conditions

for the assessment of sex and age at death. Yet, the generally good preservation of their pubic symphyses provided an array of data which served as base evidence to define age-related models for degenerative changes, such as arthropathies and tooth loss.

The results, broken down by sex classes and burial types, frame the question as to whether the cultural meaning of the aging process should play a role in defining the methodological strategies for age at death assessment. At the same time, adolescents, from 8 years old onwards, were buried according to patterns normally attested only for adults, suggesting that “biological age” and “cultural age” did not necessarily overlap.

4 ANTE MORTEM TOOTH LOSS (AMTL) – VALID AGE ESTIMATOR AT DEATH FOR ADULT INDIVIDUALS OR TOOTHLESS TIGER?

**Abstract author(s):** Müller-Schneeßel, Nils - Rinne, Christoph (Institute for Pre- and Protohistory, Kiel University) - Fuchs, Katharina (Institute of Clinical Molecular Biology, Kiel University)

**Abstract format:** Oral

It is long known that the rate of tooth loss highly correlates with age. However, and in difference to tooth abrasion, to the best of our knowledge so far no serious steps have been taken to make ante mortem tooth loss (AMTL) a candidate for the estimation of age at death. While the reasons for this seem to be quite obvious – AMTL is supposed to be due to a number of factors, not least cariogenic diet which is highly culturally specific as well as inflammation that itself can be due to different causes, and AMTL is also varying from individual to individual – the advantages warrant at least an attempt. In contrast to almost all other indicators of age, it is more or less binary – a tooth is lost ante-mortem with subsequent remodelling of bone or not – and therefore fairly unambiguous, thus it can be assessed even by the untrained eye, and it can hence potentially also applied to legacy data. Moreover, if AMTL proves to be an age estimator correlating linearly with age, it has the potential to give age estimates even for very old adult individuals, a task where most other methods of age estimation fail miserably.

In this paper, we will first introduce AMTL as inferred from modern data with known age, and then transfer these insights to archaeological case studies from the Neolithic to the Metal ages. We will show that it is possible to give linear regression formulas for the correlation between age and AMTL. With the help of Monte-Carlo-simulations, we will discuss the effects of random variation in AMTL between individuals. Further research will have to show if AMTL is a valid estimator for individuals or if it should only applied to arrive at age distributions of skeletal populations.

5 PALEORADIOLOGY AND THE ARCHAEOLOGY OF AGING: NEW TOOLS TO ANSWER OLD (AGE) QUESTIONS

**Abstract author(s):** Van Schaik, Katherine (Harvard Medical School)

**Abstract format:** Oral

As Appleby (2017), DeWitte and Stojanowski (2015), and others have noted, a longstanding methodological focus on identifying a skeleton’s chronological age has compromised efforts to evaluate and to understand assessment of biological age in archaeological contexts. As medical and scientific techniques are increasingly used to provide more thorough assessment of the archaeological remains of past populations, new opportunities are emerging to address gaps in knowledge, including those related to advanced age. Using a skeletal reference collection for which chronological age was known through coffin plates, this study places two methods of skeletal analysis – assessment by an osteologist, and analysis of X-ray images by a radiologist – into dialogue with one another. Lesion distribution and lesion burden, with reference to chronological age and sex, were compared in order to identify (1) pathologies that each methodology may overlook or misidentify, (2) how results produced by these two analytical modalities are affected by an individual’s sex, and (3) how data from osteological analysis and radiological analysis may be combined to provide more thorough and accurate assessment of the aging process in skeletons from past populations. Results demonstrated that radiographs, especially when assessed by an individual trained in musculoskeletal radiology, provided enhanced assessment of bone cortex and reduced the likelihood that interpretation of lesion burden would be unduly affected by taphonomic decay. The study provides a model by which interdisciplinary analysis and the tools of advanced medical imaging may be used to redress longstanding biases in the study of human remains from the past.

6 THE INVISIBLE ‘ELDERLY’: ESTIMATING MATURE AGE-AT-DEATH IN BURNT ADULT HUMAN REMAINS USING THE FALYS-PRANGLE METHOD

**Abstract author(s):** Veselka, Barbara (Maritime Cultures Research Institute, Department of Art Sciences and Archaeology, Vrije Universiteit Brussel; Research Unit Analytical, Environmental & Geochemistry, Department of Chemistry, Vrije Universiteit Brussel) - Hlad, Marta (Maritime Cultures Research Institute, Department of Art Sciences and Archaeology, Vrije Universiteit Brussel; Anthropology and Human Genetics, Department of Biology of Organisms and Ecology, Université Libre de Bruxelles) - Wolfe Steadman, Dawnie (Forensic Anthropology Center, Knoxville) - Annaert, Rica (Flemish Heritage Agency) - Capuzzo, Giacomo (Anthropology and Human Genetics, Department of Biology of Organisms and Ecology, Université Libre de Bruxelles) - Dalle, Sarah - De Mulder, Guy - Sabaux, Charlotte (Department of Archaeology, University of Ghent) - Salesse, Kevin (Anthropology and Human Genetics, Department of Biology of Organisms and Ecology, Université Libre de Bruxelles; PACEA De la Préhistoire à l'Actuel: Culture, Environnement et Anthropologie, Université de Bordeaux) - Snoeck, Christophe (Maritime Cultures Research Institute, Department of Art Sciences and Archaeology, Vrije Universiteit Brussel; Research Unit Analytical, Environmental & Geochemistry, Department of Chemistry, Vrije Universiteit Brussel; G-Time Laboratory, Université Libre de Bruxelles)

**Abstract format:** Oral

The Falys-Prangle method assesses age-related morphological changes to the sternal clavicle end (SCE), enabling the observation of mature adults from the 5th decade onwards in unburnt human skeletal remains. The aim of this study is to investigate the applicability of the Falys-Prangle method on burnt human remains. This is achieved by evaluating 52 SCE of 40 cremated individuals (out of 86) from the William M. Bass collection of the Forensic Anthropology Center (Knoxville, Tennessee) of known age-at-death and sex. Surface topography, porosity, and osteophyte formation are evaluated, after which the calculated composite score is associated with the corresponding age range as described by Falys and Prangle. The method is also applied on an archaeological case study from Oudenburg, Belgium, dating to the Roman period. The assessed age ranges strongly agree with the true age ranges ( $\alpha = 0.828$ ), suggesting the Falys-Prangle method to be applicable on burnt human remains. The case study from Oudenburg yields markedly improved age-at-death estimates, significantly enhancing our understanding of the age distribution within this community. Information on age-at-death is key in the construction of biological profiles of past individuals. The mature adult is often invisible in the archaeological record since most macroscopic age estimation methods do not distinguish beyond 46+ years old. Our study stresses the usefulness of a large-scale application of the Falys-Prangle method, which will increase the visibility of mature adults, especially in archaeological burnt human skeletal collections, where such information is, at present, extremely difficult to obtain.

7 AGE-AT-DEATH, CONSANGUINITY AND ARCHAEOLOGY: LEVERAGING HUMAN REMAINS FOR CHRONOLOGY AND CHOROLOGY

**Abstract author(s):** Rosenstock, Eva (Freie Universität Berlin, Einstein Center Chronoi)

**Abstract format:** Oral

The READ technique to identify consanguinity not only opens new ways to calibrate  $^{14}\text{C}$  dates derived from the respective skeletons. As a proxy for temporal relationships between skeletal individuals found in archaeological contexts, consanguinity data can also inform us about temporal relationships between stratigraphic units that contain human remains or the duration of artefact types they are associated with. However, we currently lack the necessary precision to fully embrace the potential of human remains, their individual biographies and their genetics, as long as age-at-death, an important model proxy, is anthropologically only given as broad spans of several decades or even largely biased for adult skeletons as the majority of human remains. Using Neolithic cases from settlements such as Çatalhöyük, cemeteries such as Stuttgart-Mühlhausen or Trebur and reanalyses of pooled individual data, the paper outlines in a “what-if-we...” fashion how more precise anthropological age-at-death determinations could enhance our understanding of chorology and chronology of sites, individuals and artefacts in future multi-disciplinary approaches combining age-at-death with consanguinity, stratigraphy and typology.

8 R PACKAGE MORTAAR – LIFE TABLES AS ANALYTIC TOOL

**Abstract author(s):** Rinne, Christoph - Müller-Scheeßel, Nils (Kiel University)

**Abstract format:** Oral

Accessing age at death of each individual of a skeletal population is challenging enough. To convert these data of death into more useful data to foster archaeological interpretations of the once living population, Acsádi and Nemeskéri introduced the life table approach into the archaeological discussion. Since then, more than 50 years of discussion, critique and modifications have accompanied the undoubted need of archaeologists of the information provided by life tables.

The number crunching needed for arriving at life tables is often executed within spreadsheets and in many cases forms the end of the efforts in archaeology. Instead, such life tables should be a starting point to review the information, check proposed modifications, e.g. child deficit, age class interpolations, variations by slightly changed age estimations or demographic calculations. Thus fast forward data manipulation and easy life table calculation is crucial for a fruitful investigation of age at death data lists. The “Initiative for Statistical Analysis in Archaeology Kiel” (ISAAK) has developed a R-package to allow fast and easy calculation. This R-package mortAAR, presented in this paper, facilitates a reflective practice, multiple models and subsequent analyses of the expected living population. In addition, effects of the occupancy of different age classes and their impact on the population estimate can be easily tested.

9 BAYESIAN APPROACHES IN PALEODEMOGRAPHY: ANSWERING THE QUESTION OF POORLY PRESERVED SKELETAL REMAINS

**Abstract author(s):** Lukasik, Sylwia (Institute of Human Biology and Evolution, Faculty of Biology, Adam Mickiewicz University in Poznań) - Bijak, Jakub (Department of Social Statistics and Demography, University of Southampton) - Krenz-Niedbała, Marta (Institute of Human Biology and Evolution, Faculty of Biology, Adam Mickiewicz University in Poznań) - Sinika, Vitaly (Archaeological Research Laboratory, Pridnestrovian State University named after T. G. Shevchenko)

**Abstract format:** Oral

Paleodemographic research requires having an accurate assessment of age-at-death, which, however, is hampered by poor preservation and completeness of skeletal remains. Excluding individuals with imprecise age estimations reduces the small skeletal sample sizes further. Here, paleodemography can benefit from using Bayesian methods as an alternative approach to deterministic life tables based on well-preserved osteological material, assessed according to only one or two aging methods. The aim of this study is to explore the usefulness of a range of Bayesian methods for estimating age-at-death distributions based on fragmented and incomplete skeletons, aged with several criteria. Especially for adults, such methods can allow incorporating expert opinion in the estimates through prior reference population assumptions.

In total, 312 Scythian individuals (93 children and 219 adults) from the Black Sea region were included in the study, dated to the 5th–2nd century BCE. Age-at-death was assessed using six methods depending on the availability and preservation of the skeletal material. Age categories were unified and adjusted to different aging methods to allow for application of a probabilistic assessment of age categorization. An extension of the hierarchical Bayesian model of Caussinus and Courgeau (2010) was applied, with three alternative reference populations: a hypothetical, subjective one, a real reference population, and no reference. Young adults were found to likely exhibit a high probability of death, which could result from Scythian lifestyle, conflict and wars.

Our study shows that Bayesian approaches can provide a more realistic representation of age structures based on incomplete human remains than the classical life tables, though at the expense of increased uncertainty of the estimates. The results, especially for small samples, proved sensitive to the model specification. The value added of the proposed approach for assessing age-at-death, especially for adults, is an honest acknowledgement of various sources of uncertainty in the estimation.

10 INDIRECT AGE ESTIMATION OF AN ADULT BURIED POPULATION

**Abstract author(s):** Seguy, Isabelle (Institut national d'études démographiques - Ined; Université de Nice Côte d'Azur, CNRS, CEPAM) - Batista Goulart, Luana (Université de Nice Côte d'Azur, CNRS, CEPAM) - Caussinus, Henri (Université Paul Sabatier, Toulouse) - Courgeau, Daniel (Institut national d'études démographiques - Ined)

**Abstract format:** Oral

Paleodemographers have used various methods to estimate the age structure of a buried population, for which only biological indicators are available. These methods use a reference population whose age and biological indicators are known, and make various hypotheses. They raise a number of problems, both in their underlying hypotheses and the estimates they provide, which are discussed.

We present a new fully Bayesian method which considers the frequencies observed both in the reference population and at the archaeological site under study to be random, on the hypothesis of biological uniformity between the two populations. The principles of this method are briefly presented and contrasted with those of earlier methods. The method is then applied to some archaeological cemeteries of modern France. Once the age structure at death of the site is known, it becomes possible to estimate the individual age at death of these buried people. An example is given with the plague cemetery of Martigues.

11 AN AORISTIC APPROACH TO POPULATION DEMOGRAPHY. DEALING WITH VARYING PRECISION IN AGE-AT-DEATH ESTIMATION IN AN EARLY MODERN POPULATION FROM SWITZERLAND

**Abstract author(s):** Moser, Daria (Institute of Clinical Molecular Biology, Kiel University) - Leder, Cora (Faculty of Archaeology, Leiden University) - Rindlisbacher, Laura (Integrative Prehistory and Archeological Science, University of Basel; Archäologische Bodenforschung Basel-Stadt) - Pichler, Sandra (Integrative Prehistory and Archeological Science, University of Basel)

**Abstract format:** Oral

Traditional methods of estimating age-at-death in human skeletal remains pose various problems, one of which is the degree of precision. This varies widely according to individual age and bone preservation, especially in adults. While we may be able to narrow down the age of a well-preserved infant to within a few months, older, poorly preserved individuals may only be assigned very broad age ranges spanning 20 years or more. This poses a significant challenge to demographic insight into past populations, as population-wide pooling of data is not possible unless data is categorized consistently.

We present a new solution to this problem by introducing an aoristic approach which combines existing demographic methodologies in handling age ranges of varying lengths and concepts of mortality and survivorship. Our approach proposes splitting the inconsistent age data gleaned from the osteological sample into consistent age groups of uniform length as required by the specific topic and calculate mortality for each group as proposed by Boldsen 1988 for his proportional method. To address issues raised against this method regarding the non-uniform probability of dying within the age ranges, we propose a correction through an interval censored data approach informed by known broader time- and location-specific mortality patterns (e.g. model life tables).

Our new aoristic approach thus allows for the inclusion of all individuals in demographic analyses, regardless of the precision of specific age determinations, and mitigates distortion caused by outliers. Using our new approach, we were able to show that the unusual age distribution in an Early Modern Swiss cemetery represents a catastrophic rather than an attritional mortality profile and was likely caused by an epidemic.

A. **AGE-AT-DEATH ESTIMATION FROM THE SKELETON: DEEP ANALYSIS OF PELVIC ARTICULAR SURFACES USING DATA MINING AND MACHINE LEARNING METHODS**

**Abstract author(s):** Koterova, Anezka (Department of Anthropology and Human Genetics, Faculty of Science, Charles University) - Buk, Zdenek - Stepanovsky, Michal (Faculty of Information Technology, Czech Technical University in Prague) - Bruzek, Jaroslav - Veleminska, Jana (Department of Anthropology and Human Genetics, Faculty of Science, Charles University)

**Abstract format:** Poster

Age-at-death estimation of adults remains one of the most challenging biological profile estimation parameters in both past and current populations. Many efforts have been made to develop methods that are accurate and reliable at the same time. Current research involves the 3D representation of joint surfaces and the use of geometric morphometry methods. It is assumed that such an approach offers a more objective evaluation of age-related changes than traditional visual methods often dependent on observer experience. Our contribution aims to find the most appropriate approach of data preprocessing (surface representation) and extraction of age-related pattern to estimate the age of a skeleton. We have 3D scans of several hundred of adult pelvic bones from four European and one Asian identified skeletal collections at our disposal. Several approaches were used to preprocess 3D data, such as depth map, 3D point cloud, 3D voxel representation, geometric transformation and so-called fingerprint based on surface variation or transformation according to the dominant shape of the articulation surface. We extracted patterns that might be suitable for age estimation from such pre-prepared data in the following ways. 1) Calculation of the surface variation of the scanned surface; 2) Approximation of the scanned surface by various functions to recognize the characteristic shape of this surface; 3) Determining the representative height of the scanned surface profile, and 4) Detection of significant lateral profile elevation in the scanned surface. The best approaches for surface representation and extraction of the age-related pattern will be chosen to propose an age prediction models. Preliminary results indicate that age-at-death can be estimated at narrower age intervals than the current three age classes (young adults, mature adults, and old individuals).

432 **PERSPECTIVES ON BRONZE AGE CHANGES**

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Schaefer-Di Maida, Stefanie (Institute of Pre- and Protohistoric Archaeology, CAU Kiel; CRC 1266) - Raese, Hendrik (Institute of Pre- and Protohistoric Archaeology, CAU Kiel) - Filipovic, Dragana (Institute of Pre- and Protohistoric Archaeology, CAU Kiel; CRC 1266) - Melheim, Anne Lene (Museum of Cultural History Oslo, Department of Archaeology)

**Format:** Regular session

The goal of this session is to consider changes in the European Bronze Age from different, multi- and interdisciplinary perspectives and to compare them across temporal and spatial constraints.

Our session is interested in contributions, that deal with cultural developments, which unfolded in Europe during the Bronze Age. These are often conceived as similar from region to region. For instance, the shift from inhumation to cremation was a fundamental change in funerary customs, signaling also a transformation in ideology. Moreover, we see signs of significant changes in subsistence economies and land uses: new animals and plants came into use, new storage and cultivation techniques were applied. New forms of material culture – tools and objects, such as new types of weapons - were widely distributed through dynamic and shifting networks, as documented, for example, by the numerous finds of hoards. Changes in world-view are evidenced by the spread of new rites (e.g. use of cooking pits and new burial customs) and new symbolic grammar (e.g. sun-animal symbolism).

However, these and other changes did not happen in all and every region of the continent and not at the same time or at the same pace. Clearly, Bronze Age developments took different pathways in different regions, evolving in both uniform and opposing ways.

In this session, we want to bring together and compare the developments in subsistence, society, ideology, economy, ecology, in order to get a more nuanced understanding and to lay the foundation of a chrono-sequence of changes in Bronze Age Europe. We propose to do this within the frame of human-environment relationships, as both cultural and environmental context may have influenced if and how these changes were played out in space and time. We invite contributions from, but do not limit them to, archaeology (including subdisciplines), anthropology, environmental science and geosciences.

**ABSTRACTS:**

1 **CHANGES IN TEXTILE PRODUCTION IN THE BRONZE AGE AEGEAN**

**Abstract author(s):** Siennicka, Malgorzata (University of Göttingen, Institute of Archaeology)

**Abstract format:** Oral

Textiles are hardly ever preserved in the Bronze Age Aegean (c. 3000-1200 BCE), and only a small number of mineralised textiles were discovered in the Late Bronze Age contexts. Nevertheless, we are aware that both vegetal and animal fibres and products made of skins, furs, and wool have been exploited for thousands of years to make clothes and other household items. Along with a number of cultural, social, political, technologic, and economic changes that occurred during the Bronze Age, also textile manufacture and industry transformed in many ways. With time passing, textiles and textile production have gained a new social and economic significance, and – as the Late Bronze Age written sources demonstrate – became one of the most important industries of the palatial societies. The aim of this paper is to review the changes of textile production in the Early, Middle and Late Bronze Age Greece, basing on archaeological, textual and iconographic evidence.

2 **SALT IN THE CENTRAL AND NORTH-CENTRAL ANATOLIA DURING THE BRONZE AGE**

**Abstract author(s):** Dardeniz, Gonca (Istanbul University; Department of Protohistory and Near Eastern Archaeology)

**Abstract format:** Oral

Salt is a key mineral for human history. Studies on salt in Anatolia, one of the resource-rich areas of the ancient Near East, have largely focused on determining the geological localization and capacity of the reserves. However, procurement and use of salt received limited attention especially in Anatolia. Inhabited as early as the Paleolithic, there is no doubt that the settlers of the region have been benefiting from salt through millennia.

This talk will review geological, archaeological, ethno-archaeological, and textual data to assess the role of salt within the larger economic, social, and political setting of the Bronze Age Anatolia (c. 3000–1200 BCE). While presenting estimates for the consumption for the Early Bronze Age (c. 3000–2000 BCE), when no textual records are available, for the Middle and Late Bronze Age (c. 2000–1200 BCE), my discussion of the economic value, transportation methods, and people who may have been involved in salt work is based specifically on the available textual records.

As extrapolations for the consumption based on recent fieldwork validate significant utilization during the Bronze Age, the easy accessibility of rock salt and solar-evaporated salt pans ranks salt lower among the strategically controlled materials. Even though salt appears as a circulating commodity in the textual records of the Old Assyrian Colony Period (c. 1970/1950–1750/1700 BCE), and a certain political control especially over saltlicks is documented in the Hittite Empire period accounts (c. 14th–13th centuries BCE); the centralized system molded around the powerful economic trade network and well-established economic institutions did not demonstrate any ‘visible’ demand on salt. While politically transforming from chiefdoms to empire, this seemingly insignificant demand for salt portrays Bronze Age Anatolian salt economy as different to its Mesopotamian and European counterparts.

3 **A MULTIDISCIPLINARY APPROACH TO COMMUNITY, SETTLEMENT AND SUBSISTENCE IN THE UPPER SEINE VALLEY (FRANCE) DURING THE BRONZE AGE**

**Abstract author(s):** Peake, Rebecca (Inrap; UMR 6298) - Herrscher, Estelle (Aix Marseille Univ; LAMPEA) - Auxiette, Ginette (Inrap; UMR 7041) - Balter, Vincent (Ecole Normale Supérieure de Lyon; LGL-TPE) - Delattre, Valérie (Inrap; UMR 6298) - Gouge, Patrick (Département de Seine-et-Marne; UMR 6298) - Mordant, Claude (Université de Bourgogne; UMR 6298) - Roscio, Mafalda (Eveha; UMR 5138) - Toulemonde, Françoise (UMR 7209, Archéozoologie, Archéobotanique: Sociétés, Pratiques et Environnements) - Varalli, Alessandra (CaSEs Research Group, Department of Humanities, Universitat Pompeu Fabra)

**Abstract format:** Oral

Tell me what you eat and I will tell you who you are!

The Upper Seine valley has been the focus of large-scale archaeological investigation for several decades and is now one of the most intensively researched and best understood areas of France still yielding important new information each year. Bronze Age and early Iron Age sites are numerous and well preserved, with over 70 settlements and 40 cemeteries excavated in the area forming a coherent and spatially dense pattern during this period. The area has therefore provided an abundant resource for ongoing research.

A new project set up in 2019, the Project Bronz’Pal, has focused on studying food production and consumption, diet and mobility in this area throughout the Bronze Age using a multi proxy biochemical analysis. Carbon, nitrogen and sulphur stable isotope analyses have been performed on 40 human bone, 36 animal bone and 34 cereal samples from Early, Middle and Late Bronze Age contexts (2100 – 900 cal. BC). First results suggest significant changes in diet and farming practices during this period, like the transition from a C3 plant based diet to one mainly based on C4 plants like millets and an increasing animal protein consumption during the Late Bronze Age. Furthermore, preliminary sulphur data seem to highlight the presence of individual mobility, likely more significant for men. This paper is a preliminary presentation of a multidisciplinary project that purposes to combine archaeological and isotopic data in a comprehensive approach towards a greater understanding of Bronze Age communities of the Upper Seine Valley.

4  
**BRONZE AGE INNOVATIONS IN THE EUROPEAN FOOD-PRODUCTION SECTOR: AN ARCHAEOBOTANICAL VIEW FROM NORTHERN GERMANY**

**Abstract author(s):** Filipovic, Dragana - Schaefer-Di Maida, Stefanie - Feeser, Ingo (Institute of Pre- and Protohistoric Archaeology, Christian Albrecht University, Kiel) - Dreibrodt, Stefan (Institute for Ecosystem Research, Christian Albrecht University, Kiel) - Alsleben, Almuth (Akademie der Wissenschaften und der Literatur, Mainz) - Kneisel, Jutta - Kirleis, Wiebke (Institute of Pre- and Protohistoric Archaeology, Christian Albrecht University, Kiel)

**Abstract format:** Oral

Previous large-scale evaluations of European archaeobotanical datasets unveiled the dynamic history of plant-food provisioning during the Bronze Age, which included introduction of new crops and development of new production methods. They found evidence of these changes in different parts of Europe and proposed mechanisms including trade/exchange, mobility, colonisation, merging of cultures as enabling the spread of innovations in plant economies around the continent.

This presentation examines archaeobotanical data from Bronze Age sites in northern Germany, collected or produced within the Collaborative Research Centre 1266 in Kiel. Although culturally and climatically distinct, and with asynchronous Bronze Age sequence to much of Europe, the region saw food economies experiencing similar type of changes witnessed Europe-wide. This confirms the observed convergence of local, regional and supra-regional patterns in plant-food production in the Bronze Age. The presentation then singles out several of these similar developments – the increased importance, or start of cultivation of certain crops and application of certain agricultural practices – and looks at their regional cultural and environmental contexts. It shows that changes in the food-production sector proceeded amid expanding production and circulation of diverse raw materials (from amber to metal) and objects (e.g. status symbols), socio-political reorganisation (materialised in architectural forms, grave and house inventories) and growing environmental impact of Bronze Age communities. Were the innovations in plant economies a cause or a consequence of these general developments?

5  
**CHALLENGE OR CRISIS? – ABOUT STABILITY AND CHANGE OF COPPER CIRCULATION IN LATE BRONZE AGE SOCIETIES**

**Abstract author(s):** Nessel, Bianka (Institute for Pre- and Protohistory, Johannes-Gutenberg University Mainz)

**Abstract format:** Oral

During the Bronze Age, copper production underwent several changes. A change in the use of fahlore and copper pyrite is shown by material analyses of bronze products. After the extensive exploitation of copper pyrite, central European communities faced an abrupt shortage of raw materials in the middle of the 12th century BC. This produced a reaction in economic and social terms, which is visible through the use of substitutes. This study focuses on the challenges entangled with these changes in particular regions as well as certain social and economic networks. In selected regions, the archaeological indicators of this raw material switch are examined on a supra regional level as well as strategies for coping with both short-term supply bottlenecks and the introduction of a fully functional replacement material. Human coping strategies are not seen as being characterized solely by special turning points that require an abrupt change from established behavioural patterns. Rather, it is investigated how slow and gradual transformations in human activity can be identified, mapped and correlated through analysis of aspects of communal thinking and acting, such as settlement structure, burial customs, hoarding patterns and the economic orientation of the communities in question as well as their participation in multilevel networking.

6  
**ASPECTS OF MIDDLE BRONZE AGE INTERCOMMUNAL INTERACTION AND MATERIAL CULTURE APPROPRIATION IN CENTRAL AND EASTERN EUROPE**

**Abstract author(s):** Staniuk, Robert (Institut für Ur- und Frühgeschichte CAU Kiel) - Romaniszyn, Jan - Makarowicz, Przemysław (Faculty of Archaeology, Adam Mickiewicz University in Poznan)

**Abstract format:** Oral

The mid second millennium BC represents a transition towards new forms of expressing cultural identities across different groups. The visual differentiation of standardized forms allows determination of regional fashions, while the similarity of artefacts found across culturally distinct groups points towards continued interests in maintaining ties in spite of possible cultural differences. However, the investigation of such phenomena is often challenged by the persistent reliance on classifying groups following material culture (dis-)similarities, instead of focusing on common notions of practices and their manifestations.

The focus of this paper is to overcome these challenges, by the statistical evaluation of the temporal and typological aspects of metal and pottery artefacts found in the Central and Eastern Europe (parts of the North European Plain, the Baltic-Pontic zone, Central Uplands, Carpathian Basin). Archaeologically, this corresponds to the groups such as the Tumulus culture, Vatya, Otomani/ Füzesabony, and the Trzciniec Cultural Circle.

The investigation aims at determining whether identical or similar artefacts were treated in a related fashion or whether communities appropriated artefacts for their specific cultural practices.

7  
**SETTLING DOWN SOMEWHERE ELSE. CHANGING SETTLEMENT PRACTICES FROM THE LATE NEOLITHIC TO THE EARLY BRONZE AGE IN THE SOUTH-WEST BALTIC**

**Abstract author(s):** Raese, Hendrik (Institute of Pre- and Protohistoric Archaeology, Kiel University)

**Abstract format:** Oral

Extensive archaeological field work in the course of large linear infrastructure projects (e. g. motorways and pipelines), in combination with additional site-based research, revealed a number of settlements with house structures from the very end of the local Late Neolithic and the Early Bronze Age (2200-1600 BCE) in north-eastern Germany. These are indicators for a predominantly sedentary life and long-term use of settlement areas. On the other hand, there are only few signs of permanent or intensive settlements for the greater part of the preceding Late Neolithic and for the subsequent Middle Bronze Age. Those that have been found can usually be assigned to the spatial and temporal fringes of the researched time and space. A simple explanation like emigration is not applicable in the light of numerous burial sites and stray finds from these phases. This development is comparable to the neighboring regions of the Polish Lowlands but in contrast e.g. to southern Scandinavia. Based on environmental (e.g. terrain-based, paleoclimate) and socio-cultural (e.g. visibility, transport networks, food production) data, the selection of settlement locations for the Early Bronze Age is in contrast to the preceding and subsequent time slices shall be analysed. This should help to identify different cultural trajectories and to formulate hypotheses about the change in settlement intensity and longevity.

**AT THE EDGE OF THE BRONZE AGE WORLD: A NEW APPROACH TO NORWAY’S POPULATION HISTORY**

**Abstract author(s):** Melheim, Lene (Museum of Cultural History University of Oslo) - Skar, Birgitte (NTNU – Norwegian University of Science and Technology) - Armstrong-Oma, Kristin (Museum of Archaeology, University of Stavanger)

**Abstract format:** Oral

In an era characterized by innovation, high mobility and connectivity, Norway was situated at the fringes of the grand Eurasian trajectories. So far, few biomolecular studies have been undertaken to understand the population history of Norway. Awaiting such analyses on Bronze Age material, this paper will address how a perspective from the fringe may inform current Bronze Age debates. We argue that demographic and social changes are potentially more visible at the fringe compared to the grand European melting pot.

In Norway, a second wave of farming led to a broad agro-pastoral transition c. 2500 BCE, which was accompanied by changes in settlement, ritual behavior and other material expressions including metallurgy, timber-built long-houses, and plank-built boats, and more hierarchical societies geared towards exchange and alliances. These socio-material changes have been described as a ‘cultural package’ but the demographic and social mechanisms leading to such pointed covariations in data are poorly understood. In a landscape where preconditions for farming and pastoral activity vary greatly, the region of today’s Norway was a meeting point between Eurasian cultural impulses and knowledge systems derived from foraging dependence. The societies living at the far end of the European Bronze Age world showed a high degree of regional diversity. While immigration by expansive groups from the European continent may have triggered social change, the extent and character of actual migrations of foreign people into Norway are unknown.

This paper will approach processes of cultural transfer in an original way through a focus on knowledge systems, thus breaking down academic divisions between categories of material evidence. It is argued that a systematic investigation of knowledge systems offers a new and uncharted avenue to approach cultural complexes, cultural entanglement and societal change.

**THE LAST SEQUENCE OF THE BRONZE AGE IN TRANSYLVANIA IN A EUROPEAN CONTEXT**

**Abstract author(s):** Wittenberger, Mihai (National History Museum of Transylvania)

**Abstract format:** Oral

With an area of 102.834 km2 of which 190 km2 are the Carpathian Mountains is one of the richest historical provinces of Romania (238 397 km2). With a current stable population of 7-8 million, it provides 2/3 of GDP.

Going back to prehistory when between 50,000 and 100,000 inhabitants lived in the same perimeter, we can get an idea of how rich and powerful they were. The mineral riches of Transylvania are: salt, gold, copper and tin. But the most important wealth was and are PEOPLE !! Animal husbandry and agriculture are other notable resources.

The middle bronze cultures of the Carpathian space were: Wietenteberg (central and NW Transylvania) Ottoman NW, Costisa and Monteoru (east). Around the middle of the second millennium ICh appears the Noua culture with new elements of metallurgy.

The departure of the “peoples of the sea” disturbed the whole of Europe: the disappearance of the goals from present-day Hungary, the attempted invasion of Egypt, the disappearance of the Hittite empire. However, Transylvania is seen differently. There were no fortified settlements throughout the Middle and Late Bronze Age. In other words, we can’t talk about invasions.

The people of Transylvania were rich and strong enough militarily to reject anyone or to make peace! The presence during this period of over 7,500 artifacts (glass, amber, ceramics, bronze) in the cave cave of Cioclovina, present in Uioara hord more like 6000 bronz objects is proof that production and trade routes continued to operate uninterrupted from the Minoan era until the end of the Bronze Age.

UP IN FLAMES: COMPARING PROVENANCE AND CONTEXT IN EARLY AND LATE BRONZE AGE CREMATION BURIALS FROM SEVERAL AREAS IN DENMARK

**Abstract author(s):** Reiter, Samantha (National Museum of Denmark) - Møller, Niels (Museum Thy) - Nielsen, Bjarne (Vesthimmerlands Museum) - Bech, Jens-Henrik - Olsen, Anne-Louise (Museum Thy) - Schjellerup Jørvok, Marie (Copenhagen Univesity) - Kaul, Flemming - Mannering, Ulla - Frei, Karin (National Museum of Denmark)

**Abstract format:** Oral

Oestigaard describes cremation as “not one, but many funeral practices” (2013: 497). Over the course of the Nordic Bronze Age, the many nonstandard configurations of cremation burials from the early periods settled into the stricter, less varied pattern we recognize from the Late Bronze Age. In this way, there was an evolution from many ‘ways’ of depositing cremations into one more standardized pattern. In order to shed light on the uptake of cremation as a new burial practice and its eventual integration as the dominant mode of funeral deposition, this paper presents data from 19 new provenance analyses from Early and Late Bronze Age contexts within Denmark from the regions of Thisted County and Vesthimmerland (both from Jutland) and the island of Zealand. These data are compared with data from other extant relevant studies, including those from Late Bronze Age Fraugde on the Danish island of Fyn. By addressing habitus in relation to the deposition of cremations as juxtaposed with these provenance data, we hypothesize several potential pathways for the uptake of cremation as a new cultural practice within the Danish Nordic Bronze Age.

RITESCAPES AT THE EDGE OF THE BRONZE AGE WORLD

**Abstract author(s):** Henriksen, Merete (NTNU University museum, Department of Archaeology and Cultural history) - Brück, Joanna (University College Dublin)

**Abstract format:** Oral

This paper will examine how intercultural encounters at the edge of the Bronze Age world are reflected in ritual practice. Taking as our focus Late Neolithic and Early Bronze Age sites in central Norway, including depositions of human bone and other artefacts in mortuary, bog and cave contexts, we will address cultural diversity and syncretism in the ritual expressions of hunter-gatherer and farming communities as they negotiated a period of profound social and economic transformation. Population change at the start of the Bronze Age is often invoked to explain the marked turn to agriculture at this time. Yet, sites such as the rock shelter on the island of Lines, which produced ornaments of reindeer antler that mimic similar artefacts of amber made by farming communities further south, suggest that processes of change were not unidirectional but involved complex forms of intercultural engagement and interaction. Current models of Bronze Age cosmographies take relatively little account of local and regional variability in ritual practice, and have as yet to explore how communities adopted and adapted novel ideas to fit their own particular material and historical conditions. This paper will examine how ritual practices allowed different groups to make sense of their lives during this major period of lifestyle change as well as to negotiate new social and political relationships.

PLANTS AS FOOD AND FUEL IN THE YOUNGER BRONZE AGE: THE EVIDENCE FROM DOBBIN, NORTH-EASTERN GERMANY

**Abstract author(s):** Oelbüttel, Merle (Institut fuer Ur- und Fruehgeschichte Kiel) - Schroedter, Tim (freelance) - Kneisel, Jutta - Kirleis, Wiebke (Institut fuer Ur- und Fruehgeschichte Kiel)

**Abstract format:** Poster

The Younger Bronze Age in northern Germany (c. 1100 – 500 BCE) witnessed an exceptional diversity of cultivated and gathered plant resources. The archaeobotanical records from this period show presence of crops and gathered plants not seen in the assemblages from preceding periods (e.g. broomcorn millet, faba bean, gold-of-pleasure). Moreover, some previously minor crops (e.g. pea and flax) may have gained in importance at the end of the 2nd millennium BCE.

The Younger Bronze Age site of Dobbin 27, located in north-eastern Germany (Mecklenburg-Vorpommern) is situated on a sandy hill surrounded by lakes and lowlands. It preserved remains of a residential structure and domestic activity, such as postholes, pits and fireplaces. From these features, charred seeds and fruits, and wood charcoal, were extracted through sampling and flotation, and analysed.

The site yielded an archaeobotanical assemblage that very well documents the evolution to a wide selection of plant resources characteristic of the larger region. Besides crop cultivation, also attested through the presence of weed seeds, gathering of wild plants is evident based on the finds of, for instance, hazelnut.

The charcoal assemblage is similarly diverse, particularly in the pits, where the remains of wood used as both fuel and raw material are preserved. Charcoal record from the fireplaces, presumably representing their last use only, is taxonomically less rich and includes species used as fuel. The combined archaeobotanical and anthracological evidence vividly illustrate the broad spectrum of plant food and fuel resources and their changes in the Younger Bronze Age, demonstrating the importance of both wild and cultivated parts of the landscape.

POST-MEDIEVAL EUROPE AND WIDENING HORIZONS

**Theme:** 4. Globalisation and archaeology

**Organisers:** Mytum, Harold (University of Liverpool) - Larsson, Anton (Stockholm University)

**Format:** Regular session

Post-medieval Europe experienced profound social, economic and cultural change which was both represented in material culture and landscapes. Moreover, these changes were in part communicated and mediated through the material world. This session investigates comparative experiences of such changes across the period from the 16th to the 20th century, and across the varied regions of Europe. How were new religious horizons expressed materially, and what ways were in the processes and effects of the Reformation and the Counter-Reformation reflected in archaeological remains? To what extent are the new beliefs and behaviours, and the ways in which confiscated church resources were reallocated and used in the early modern, visible in the archaeological record? Widening horizons and the expansion of contacts with, and exploitation of, the rest of the globe transformed economies across Europe. What were the impacts in eastern European and the Mediterranean world compared with those of western and some northern European countries? Does archaeology reveal how new horizons in science and technology led to the transformation of production and consumption of goods? Widening horizons of possession and materialism, partly also fed by colonialism and migration, led to industrialisation and the effects on the climate that we see today; how do artefact studies increase our understanding of these processes? Post-medieval and historical archaeologists widen archaeology’s horizons to understand the present in the light of the last half millennium of our history.

ABSTRACTS:

THE RISE AND FALL OF THE ICELANDIC EARLY MODERN ROTARY QUERNSTONE AND ITS ARCHAEOLOGICAL PRESENCE 100 YEARS LATER

**Abstract author(s):** Beck, Sólveig (University of Iceland)

**Abstract format:** Oral

The aim of this paper is to relate the story of the Icelandic Early Modern rotary quern from its revival in the late 18th century to its abrupt abandonment in the early 1900s, and demonstrate how history is physically represented in the remaining Icelandic quernstone collection. The analysis is based on seven years of PhD research into available historical sources regarding the quernstone revival and its execution, into the general availability of indigenous raw materials, quernstone import and detailed analyses of the Icelandic 18th-20th century quernstone collection. In late-18th century Iceland a governmental decision was made to start importing unground grain and revive indigenous quernstone production. Rotary quernstones had not been imported to the island for a long time and local production of querns was minuscule and highly localised. Fairly quickly local quernstone production was taken up and maintained by subsistence farmers and farming craftsmen all around the island and import of foreign querns and millstones began. Quernstones could be acquired at varied prices, depending on their origin and level of complexity in their material composition. This made them accessible to all levels of Icelandic rural society and the rotary quernstone became an integral part of daily life. As import of cereals increased after the early 19th century, more modern European milling technologies and traditions were slowly finding their way to Iceland, but they were abandoned fairly quickly as ocean transport capabilities improved and the Roller Milling Revolution changed cereal processing drastically and irrevocably on both sides of the North-Atlantic.

THE WASTE RESERVOIRS: FROM EARLY MODERN PROTO-ECOLOGY TO PRESENT-DAY BIOARCHAEOLOGY

**Abstract author(s):** Larsson, Anton (Stockholm University)

**Abstract format:** Oral

As the natural sciences developed in the Early Modern period, what can be described as a proto-ecological vein was born among some naturalists, often sparked by colonial interactions. Other scholars instead favoured the unrestricted exploitation of the natural world. These competing trends would have consequences on the Swedish West Coast, where the hundreds of factories built in the mid-18th century following a boom in seasonal herring migrations spawned an intense fear of marine pollution. Although not known in such terms, what we now know as cultural eutrophication was successfully identified and targeted in fierce arguments between proto-ecologists and industrial lobbyists, the latter of which eventually saw defeat. The first environmental debate and subsequent regulations of Sweden would have material consequences well into the 19th century, leaving dozens of surviving sites behind to be studied today. This paper presents the archaeological remains of this decade-long conflict, which now two centuries on can serve as vital sources of bioarchaeological data.

3 **WIDENING HORIZONS IN POST-MEDIEVAL IRELAND: AN INVESTIGATION OF FOOD CULTURES**  
**Abstract author(s):** McClatchie, Meriel (University College Dublin) - Flavin, Susan (Trinity College Dublin) - OCarroll, Ellen (University College Dublin)

**Abstract format:** Oral

The 16th and 17th centuries in Ireland were a period of increasingly globalised trade. New foods arrived in Ireland, some of which, such as the potato, eventually became dietary staples. Irish food cultures were also influenced by neighbouring Britain, but some food choices reflect the persistence of more local traditions, such as the predominance of oats in certain social contexts. The ERC-funded “FoodCult” research project (<http://foodcult.eu>) is seeking to understand the nature and meaning of food in Ireland during this period, and how the material expression of food can provide new insights into beliefs and behaviours. FoodCult is collating and analysing data from archaeobotany, zooarchaeology and artefact studies (such as cooking and eating utensils), reflecting remains that have been recovered from a wide variety of urban and rural excavations. FoodCult is also undertaking new scientific investigations, including stable isotope and lipid analyses. These new archaeological and scientific analyses are being integrated with evidence from historical sources, providing a ground-breaking new approach to understand food and identity in a complex society. This paper will explore evidence from plants, focusing on cereals and fruits, highlighting the challenges of an interdisciplinary approach, key gaps in knowledge, and how the FoodCult project is addressing these issues.

4 **WIDENING HORIZONS: EXPLORING HEALTH, DISEASE, AND DIET IN INDIVIDUALS FROM THE POST-MEDIEVAL RIVERSIDE VILLAGE OF SARILHOS GRANDES (MONTIJO, PORTUGAL)**  
**Abstract author(s):** Pereira, Paula (Independent Resercher) - Jesus, Roger (CHAM - FCSH-NOVA; CHSC - UC) - Santos, Ana Luísa (Research Centre for Anthropology and Health, Department of Life Sciences, University of Coimbra) - Magalhães, Bruno (Department of Life Sciences, University of Coimbra)

**Abstract format:** Oral

Two excavation campaigns (2008 and 2020) in the São Jorge’s church graveyard established the basis for the research project SAND (Sarilhos Grandes: Between Two Worlds) concerning the role of this village, located in the south bank of the Tagus River overlooking the city of Lisbon, in the Portuguese maritime expansion (15th-17th centuries). This work aims to investigate the archaeological contexts and the architecture of death, the social and cultural behavior; health/disease, and diet of its population revealed by skeletal remains and historical documentation. A minimum number of more than 100 individuals was identified amongst the 41 burials (15 non-adults, 24 adults, two undetermined; eight males, seven females, 26 undetermined) and commingled remains in a still ongoing project. All were macroscopically inspected and isotopic, paleoparasitological, and calculus analyses were undertaken. The individuals analyzed present evidence of several diseases such as syphilis, smallpox, benign tumors, nutritional stress, different patterns of fracture, or oral pathology. Isotopic analysis has shown a varied diet of the four individuals studied, which were confirmed by the historical and paleoparasitological investigations, the last also giving new insights concerning the introduction of the potato in Europe. The fungus *Candida albicans* was identified in the calculus of one individual (the fungus may give origin to caries, a type of lesion present in the individual’s dentition), as well as eggs of a parasite from the *Trichostrongylus* genus, that had not yet been identified in European past populations. The results point to an early contact between Sarilhos Grandes and the New World and additional analyses are currently being developed to expand this study.

5 **COFFIN PLATES AND ABOVE-GROUND MEMORIALS: TWO FORMS OF IDENTIFICATION COMPARED**  
**Abstract author(s):** Mytum, Harold (University of Liverpool)

**Abstract format:** Oral

Crypts and their contents sit within a wider set of material culture associated with death, and need to be considered as part of the wider expenditure associated with a death, the funeral and any subsequent commemoration. Many coffins within crypts and brick or stone-lined graves can have well-preserved coffin fittings, including name plates. In Britain, these can be part of an elaborate assemblage of items that comprise the coffin, and these will be briefly described. The main focus of the paper, however, will be to compare the text and symbolism of coffin name plates with those of above-ground memorials, both internal and external. There are some significant similarities but also differences. These are in part because of their varied functions of coffin name plates and memorials. More significant, however, are the different power relationships between the bereaved and the undertakers very soon after the death, compared with the bereaved and the monumental mason often many months after interment. The bereaved are in a state of shock and have little opportunity to have high levels of influence on the coffin fittings beyond an agreement of a price, which then dictated the elaboration of the fittings. In contrast, the bereaved have greater agency and influence on the material product that appears as a memorial, and in particular drive stylistic change which is limited in the case of fittings.

436 **CREATIVITY AND RESOURCEFULNESS ONLINE: HOW ARCHAEOLOGISTS AND HERITAGE EDUCATORS OVERCAME THE PANDEMIC AND REACHED THE PUBLIC IN NEW WAYS**

**Theme:** 3. The new normality of heritage management and museums in post-Covid times  
**Organisers:** Fonseca, Sofia (Teiduma, Consultancy on Heritage and Culture; German Archaeological Institute; ICArEHB- UAlg) - Thomas, Ben (Archaeological Institute of America)

**Format:** Regular session

Even before the COVID-19 pandemic, online learning and outreach efforts were on the rise. The pandemic highlighted the importance of virtual tools for providing information and resources and for allowing people to stay connected with each other. Transitioning to an exclusively online world was particularly hard for archaeological outreach and education activities that rely heavily on in-person programs.

Responses to the pandemic were varied. The rapidness of the onset of pandemic-related lockdowns and quarantines, in many cases, did not allow for a careful and methodical transition. Many organizations tried to adapt their programs for a virtual world. Over time, the approach to online education and outreach changed. As people became more familiar with online tools and their potential, they adopted creative approaches to engaging and educating their audiences. They also realized that the virtual world was accessible to a larger audience. As a result, we were made aware of programs that utilized online and virtual resources to engage new publics, transmit knowledge, create accessible online courses, organize international events, and even increase the number of visitors or members at museums and cultural associations.

In this session, we plan to discuss several new and different approaches adopted, created, and implemented by individuals and organizations to communicate with the public during the pandemic. We want to hear about specific programs, how they worked, evaluate success (or failure), and discuss the future of online programming. While we believe that in-person programs will once again be offered in the future, it is clear that online programming is here to stay and who organize outreach programs and activities will consider hybrid approaches addressing the needs of in-person and online audiences. We invite anyone who planned, organized, and implemented online and virtual programming during the pandemic to share your thoughts and insights with us.

ABSTRACTS:

1 **NOT THAT NEW, BUT STILL BETTER: ONLINE ENGAGEMENT DURING THE FIRST CONFINEMENT OF THE COVID-19 PANDEMIC IN SPAIN**  
**Abstract author(s):** Almansa-Sanchez, Jaime (Incipit, CSIC)

**Abstract format:** Oral

During the first week of the confinement in mid-March 2020, I started receiving a lot of cultural offers online. These offers included free access to repositories of films, theatre, books, as well as some virtual tours and resources for archaeological museums and sites. I decided that this was the perfect moment to evaluate the reach and reception of such offerings and conducted a small survey for the Spanish audience.

This shows the main results of the survey, as well as the reflections they encouraged. It focuses on three aspects:

- Reach: Did the offerings reach new audiences?
- Experience: Did people enjoy the offerings?
- Potential: Were the offerings any different?

Although the general results are good, a closer look to the data offers a more critical perspective of the reality of those first weeks (and further on), that should help us to consider better forms of digital engagement for the post-pandemic era.

2 **A GLOBAL EVENT DURING A PANDEMIC: CELEBRATING INTERNATIONAL ARCHAEOLOGY DAY THROUGH ONLINE ACTIVITIES AND CONTENT**  
**Abstract author(s):** Langlitz, Meredith - Thomas, Ben (Archaeological Institute of America)

**Abstract format:** Oral

International Archaeology Day (IAD), 2020 had to be transformed from a global celebration that typically features in-person community activities to a virtual event because of the COVID 19 pandemic. Even before the pandemic, the AIA used to organize online activities for IAD to make the programming more accessible to a broad audience. Little did we know that this shareable digital approach would become a necessity for us and so many of our collaborators. The suddenness of the pandemic-related shutdowns did not give us much time to adjust and adapt to a new reality. Realizing that many people were looking for activities that they could do from home we decided to organize a series of virtual experiences and activities, some of which had been planned for the fall as supplements and complements to IAD activities. In this paper we will discuss several of these initiatives, the lessons we learned from them, and the future of these programs that were developed or repurposed for the pandemic. We created several new programs for this effort including Build Your Own Monument, Tweetathons, and ArchaeoDoodles. We repurposed existing program like our Lecture Program, transforming it from an in-person program to a series of webinars. We also partnered with existing programs like Skype a Scientist to create an archaeology week that featured five archaeology lectures on a range of topics and with the Veterans Cura-

tion Program to create virtual content by hosting an “Artifact of the Day” feature through social media. These efforts allowed us to increase our online content, collaborate with and showcase the work of our partners and collaborators, and experiment with online programming in a manner that we had not tried before.

### 3 COMMUNITY AND NETWORKS IN A DIGITAL AGE: COMING TOGETHER TO LEARN NEW WAYS TO PRESENT PUBLIC PROGRAMS DURING A PANDEMIC

**Abstract author(s):** Thomas, Ben - Langlitz, Meredith (Archaeological Institute of America)

**Abstract format:** Oral

In 2020, prior to the onset of the COVID 19 pandemic, the Archaeological Institute of America (AIA) was looking forward to celebrating the 10th anniversary of International Archaeology Day (IAD). Typically, IAD features locally organized community events presented by a variety of archaeological organizations across the globe. These organizations join the celebration as collaborators with the AIA. We were planning for the 10th anniversary to be the largest celebration to date, expecting to add more collaborators and more events to provide as many people as possible throughout the world the opportunity to partake in local events. The pandemic changed all our plans. Many of our collaborating organizations had to close their facilities and cancel programs. Staff were furloughed or in some cases let go. Organizations that relied heavily on in-person activities and programs had to find ways to continue operating while in a shutdown. As we faced the reality of the pandemic, we grew concerned about our collaborators: how were they faring with most public facilities closed? Were they able to continue working or were they subject to furloughs and budget cuts? How do you present public programming when the public cannot come to your facility and in-person interactions are inadvisable? Beginning in May of 2020, the AIA reached out to its network of Collaborating Organizations through a series of listening sessions. We hosted 19 online listening sessions with over 150 participants. We started with broad conversations about challenges and how people were adapting. Over time, we transitioned to themed sessions with specific goals such as troubleshooting common problems; sharing technical experiences and expertise; and facilitating conversations about critical issues. In this paper we discuss what we learned through these sessions about archaeological programming, but more importantly, about the importance of a supportive community.

### 4 THE HERISTEM (STEM IN HERITAGE SCIENCES) PROJECT: COMMUNICATING ARCHAEOLOGY DURING THE PANDEMIC

**Abstract author(s):** Vukovic, Jasna (Department of Archaeology, Faculty of Philosophy, University of Belgrade) - Šošić Klindžić, Rajna (Department of Archaeology, Faculty of Humanities and Social Sciences, University of Zagreb) - Babić, Staša (Department of Archaeology, Faculty of Philosophy, University of Belgrade) - Novaković, Predrag (Department of Archaeology, Faculty of Arts, University of Ljubljana)

**Abstract format:** Oral

The HERISTEM project (funded by the ERASMUS+ program) is designed as a strategic partnership of universities, museums, institutes for the protection of cultural heritage and small private enterprises mostly from the area of the former Yugoslavia (Belgrade, Zagreb, Ljubljana, Sarajevo), and complemented by the University of Cambridge. The project’s principal aim is to share expertise and experiences in applying various STEM sciences to archaeological academic and preventive research, public presentation of heritage, and business models in the heritage-related sector. To this end, project designers planned a series of workshops, practical training courses, staff and student exchange grants, joint publications, seminars, and conferences.

The project started in October 2019, but due to the COVID-19 breakout, much of its activities were stopped. The project’s program and its implementation had to be reconsidered. What was left open was the internet, and new ideas were needed to fill in the gap. How could we make the project’s ‘zooms’ more interesting and engaging than ‘everyday ‘zooming’? Some answers came spontaneously rather than being programmed in advance. The first such spontaneous initiative was the Archaeological Dialogues Without Isolation – a video conference, that grew from the few initial ‘dialogues’ organized once a week, into 21 discussions over four months combined with more than 30 hours of videos. Another challenge was the European Researcher’s Night. With more than seventy 2-3 minutes long videos explaining bioarchaeology and archaeology of food to a lay audience, the project hoped to find a niche that distinguished it from the mass of video presentations available at this event. Another challenge was how to make an engaging virtual exhibition for an audience that had tens of thousands of different content just one click away? In this discussion, content produced for the HERISTEM project will be presented.

### 5 INNOVATIVE WAYS OF EXPLAINING ARCHAEOLOGICAL HERITAGE IN TIMES OF COVID-19: THE USE OF DIGITAL MODELS AND 3D-PRINTING IN UNIVERSITY EDUCATION

**Abstract author(s):** Díaz-Navarro, Sonia (University of Valladolid) - Sánchez de la Parra-Pérez, Santiago (University of Salamanca) - Tejedor-Rodríguez, Cristina - Rojo Guerra, Manuel (University of Valladolid)

**Abstract format:** Oral

On subjects related to Prehistory, the study of Archaeological Heritage is a fundamental pillar for learning about how societies that left no written trace lived. Normally, students receive an explanation of the material culture accompanied by 2D graphic resources –photographs, videos, or slides– and complemented by field trips to museum institutions or archaeological sites. Since 2020, the COVID-19 pandemic has avoided the development of such practices through which students can understand archaeological context and see the most significant artefacts. From this premise arises the Teaching Innovation Project of the University of Valladolid

-“Archaeological Heritage in your hands. 3D replicas to deepen the knowledge of Prehistory”, the main objective of which is to ensure the optimal development of the subjects of Prehistory; replace fieldtrips; and promote active learning of Archaeological Heritage through the creation of reference collections, both digital and physical, of the main artefacts of the material culture of European prehistoric societies. To this end, the blended lectures have been complemented with 3D digital models of the artefacts present in free web repositories. In addition, 30% of the final mark was based on the students’ mastery of the Sketchfab web platform, in which they had to create reference collections according to their chronocultural context, typology, raw materials, etc. Later, they could touch and manipulate some of these iconic objects thanks to the 3D printing and post-processing of replicas on a real scale. Finally, the students were able to manipulate some of these objects on a real scale thanks to 3D printing and post-processing of the most significant ones. This project has allowed the development of the Prehistory subjects in a normal way, encouraging the use of new technologies in the university lectures, and facilitating the chronocultural identification of each artefact.

### 6 RECRUITING NEW STUDENTS DURING THE LOCKDOWN

**Abstract author(s):** Novakovic, Predrag (University of Ljubljana)

**Abstract format:** Oral

I don’t recall that the EAA ever discussed how the high school students were approached to enrol in the universities to study archaeology. Traditionally, for this purpose served different types of ‘open days’ or ‘information days’ where potential students could visit the archaeology departments, listen to some introductory presentation, participate in a demonstration of archaeological work etc. Some online presentations accompanied such events, but the universities considered the ‘open days’ the most important activity in recruiting new students. With the COVID-19 lockdowns which prevented the actual visits of new students, the situation has changed considerably.

Slovenia has one of the longest lockdowns in Europe, with schools forced to teach online since mid-March 2020. The most affected are the final-year (4th) high school students who studied online the whole second semester of their 3rd year and first semester of the 4th year. In addition to this, they had to finish the high-school graduation exams and decide what to study and where.

Department of Archaeology, University of Ljubljana, attempted a new approach to the ‘overzoomed’ high-school students. Information about the curricula, admission conditions and other important issues concerning the studies, prioritized in the in-vivo meetings was placed behind short introductory/promotional videos. The videos were intentionally made more ‘elliptic’; to ‘represent’ the subjects in a more entertaining way, with short and catchy slogans and phrases, dynamic intros with music, in a graphic and visual style closer to the senior teenagers. The idea was to ‘catch’ the attention with engaging content and steer the visitors into more ‘serious’ topics. The results exceeded our expectations. In four days of the Information Days peak, our internet media attracted ten times more visitors than ever before. We are aware that they were not all high-school students; the videos greatly impacted the present students and alumnae.

### 438 TRACING BAPTISM IN THE ARCHAEOLOGICAL RECORD

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Donnelly, Colm (Archaeology & Palaeoecology, School of Natural & Built Environment, Queen’s University Belfast) - Guillon, Mark (Inrap & PACEA UMR 5199 CNRS Université de Bordeaux) - Murphy, Eileen (Archaeology & Palaeoecology, School of Natural & Built Environment, Queen’s University Belfast) - Portat, Émilie (Direction de l’archéologie, Chartres Métropole UMR - CNRS 7041 ArScAn, TranSphères)

**Format:** Regular session

Baptism is a sacrament of critical importance within the main Christian denominations. Within the early Christian church it was considered essential to cleanse a person of Original Sin, the sin committed by Adam and Eve in the Garden of Eden and subsequently inherited by humankind ever since. If baptism did not occur, however, then the sin remained in place and, as such, the unbaptised were condemned to Hell. A strong advocate for this position in the early church was St Augustine of Hippo (AD 354–430) who believed that all infants should be baptised as soon as possible after their birth in order to avoid potential eternal damnation should they die unbaptised. This harsh doctrine was later modified by moderate theologians within the Medieval church who advocated the existence of Limbo. By the late 16th century, however, baptism had become a contentious issue between the Catholic Church and the Reformed Churches, and also within Counter-Reformation Catholicism with certain theologians placing extreme importance on the teaching of St Augustine and his views on what happened to the souls of the unbaptised after death and their burial in unconsecrated ground.

It is the intention that this session will provide new insights and challenge existing paradigms on baptism through approaches that include material culture, scientific, theological, historical, and architectural perspectives and approaches. Papers are invited to cover issues such as burial rites and practices for the unbaptised (e.g. children’s burial grounds), the material culture associated with baptism (e.g. religious objects and clothing), and the architectural expression of baptism (e.g. sanctuaires à répit [respite sanctuaries], shrines, and baptismal fonts). Papers that focus on the scientific analysis of infants that might provide insights concerning whether or not they were live or still born and hence potentially baptised are also welcome.

ABSTRACTS:

1 AN INNOCENT SOUL BECOME AN ANGEL. NEWBORN BURIALS IN MEDIEVAL AND POST-MEDIEVAL BOHEMIA

**Abstract author(s):** Cechura, Martin (The Museum of west Bohemia, Pilsen)

**Abstract format:** Oral

Graves of infants and children belong to a specific category of medieval and modern-age burial culture. Special zones have been identified at a number of archaeological sites in Czech Republic dedicated to burying new-born babies. These zones are often located near a church, but their location is quite variable. However, there are other specific places in the cemetery area. The most important of these are burial places near the cemetery wall, both inside and outside, or even in recesses of the cemetery wall. There is also a special case of desecrated or more or less dilapidated churches. Specific are also multiple graves of a child and an adult. In interpreting the archaeological facts it is necessary to use other types of sources, especially written and ethnographic, bearing in mind the great variability of the written sources, which for each archaeological phenomenon offer more varieties of interpretation. The result of the archaeological analysis is the finding that the burials of deceased new-born babies required special treatment and were given great attention. Whatever the reasons, this fact illustrates a clear understanding of the childhood category since birth, and the strong emotional bond linking parents and deceased children. In these examples we see a strong effort to secure the new-born a respectable funeral in the cemetery.

2 IDENTIFYING BAPTISM IN LATE MEDIEVAL AND THE EARLY MODERN CATHOLIC WORLD FROM EXCAVATIONS. APPROACHES FROM HISTORY, ARCHAEOLOGY AND PHYSICAL ANTHROPOLOGY

**Abstract author(s):** Guillon, Mark (Inrap; University of Bordeaux) - Portat, Emilie (Chartres City France; University of Paris 1) - Partiot, Caroline (University of Bordeaux)

**Abstract format:** Oral

This paper will deal with the possibilities of identifying baptism in the late middle ages and early modern period, crossing results from historical sources, archaeology and physical anthropology. Historical sources are texts, parish registers plus religious architecture and topography. Archaeology and physical anthropology consist of the study of graves (mortuary gestures, coffins, shrines) and human remains of fetuses, perinates and infants. We begin with the results from the excavation and study of the Catholic church and graveyard of Saint-Ayoul (Brie county, France) near Paris. The presentation focuses on the problem of how to prove baptism for very little ones from archaeological samples in the early modern Catholic world. We will also make a point on the biological possibility of proving if a baby was live born. Apart from the research being developed, but not validated, on the biochemical alterations specific of post-partum acquired bacteria, the only reliable indicator remains, up to now, the neonatal line, a disruption in the formation of tooth enamel due to birth-induced stress. As this analysis requires time-consuming and destructive histological protocols, it is far from being applied regularly. However, new approaches based on the plasticity of the perinatal development aim to investigate the impact of the transition from intrauterine to extrauterine environment on both skeletal growth and musculoskeletal maturation processes. Is a holistic approach possible around the problem of catholic baptism?

3 ‘EAVES -DRIP-BURIAL’ AND RETROACTIVE BAPTISM: VALID INTERPRETATION OR INSUFFICIENT CITATION PRACTICE?

**Abstract author(s):** Hausmair, Barbara (University of Innsbruck)

**Abstract format:** Oral

In Christian cemeteries across medieval and modern-period Europe burials of perinates, neonates and infants are frequently found close to the church walls, which has led to their denomination as ‘eaves-drip burial’. Although this term adequately describes the position of such burials under the church’s eaves, it has become common to also use it as a proxy for the interpretation of such practices as attempts to provide a kind of retroactive baptism through rainwater dripping from the church roof onto the graves of presumably unbaptized children. A thorough review of recent research shows that this interpretation is widely employed in archaeological research regardless of the chronological (medieval, modern-period), geographical (West, Central and Southern Europe) or cultural context (medieval Latin Christianity, modern period reformed or counter-reformed contexts) of specific case studies. Yet, a close look reveals considerable differences in age distribution and spatial patterns of ‘eaves-drip burials’ in different regions and time-periods. Additionally, primary sources that would support the ‘eaves-drip burial = retroactive baptism’ equation stem almost exclusively from protestant and reformed areas (16th century onwards) and are rarely referred to in archaeological scholarship. It is the aim of this paper to draw attention to the risk of creating circular arguments within academia and producing historical narratives that are difficult to support if our interpretations are solely based on secondary literature form within archaeology. A chronologically, structurally and bioarchaeologically sensitive approach towards ‘eaves-drip burial’ together with a more thorough consideration of contemporary written sources on folk beliefs and baptism practices is proposed in order to critically review the notion of retroactive baptism and to gain more nuanced insights into the broad variety of beliefs and burial practices related to ‘eaves-drip burial’, baptism and mortuary space in different time-periods and regions.

4 UNBAPTISED AND BAPTISED INFANTS AND THEIR BURIALS IN EARLY MODERN FINLAND AND SWEDEN

**Abstract author(s):** Lipkin, Sanna (University of Oulu)

**Abstract format:** Oral

Attitudes towards unbaptised children and their burial varied in Finland and Sweden through time. In rural areas, the parents were instructed to bring their children to be baptised as soon as possible; even one week was considered to be too long a waiting period. Between the 17th and 19th centuries, the attitudes of the parish priests were important. Some unbaptised newborns were buried in silence whereas others received full funeral sermons. Until the 19th century, at some church yards newborns were often buried separately from others, close to the church fence. Both ethnographic and archaeological evidence implies that some prematurely born infants were buried in small cases inside church fences and walls. Similar cases have been found under several churches both in Finland and Sweden. Their presence suggests that baptism was not a prerequisite to burial under the church floor. Examples below the church floors also imply that prematurely born infants and newborns were buried close to the elderly probably to seek protection from them. Some unbaptised infants were also hidden under funerary clothes or bedding in adults’ coffins. This presentation will consider the burial customs of both baptised and unbaptised infants both through burial location and funerary attire (christening gowns, caps and belts as well as silk tapes and laces). Even though in the eyes of the church, the baptised infants were treated as a part of the parish, the burials of the unbaptised infants indicate that care and dedication was also given to their burials.

5 BURIAL BEFORE BREATH: A MULTIDISCIPLINARY INVESTIGATION INTO THE SOCIAL IMPACT OF FOETAL AND MATERNAL MORTALITY DURING THE INDUSTRIALISATION OF ENGLAND

**Abstract author(s):** Knox, Elizabeth (The University of Sheffield; Museum of London Archaeology - MOLA)

**Abstract format:** Oral

Burial Before Breath is an Arts and Humanities Research Council funded collaborative doctoral partnership between the University of Sheffield and Museum of London Archaeology (MOLA) examining the social impact of foetal and maternal mortality during the industrialisation of England. This presentation will introduce one aspect of the author’s research, to investigate the funerary rites and rituals, or lack thereof, associated with unbaptised infants, specifically foetal remains excavated from multiple archaeological sites across England dating to the Industrial period.

The burial of unbaptised infants, including stillborn and neonates dying shortly after birth, was prohibited within consecrated grounds. However, skeletal remains archaeologically excavated from burial sites across England suggest this rule was not always followed or was creatively stretched to allow their inclusion. Preliminary observations regarding how the burial of foetal remains within Christian burial grounds differed from older children and adults will be discussed as well as the impact this had on the Industrial English family, as demonstrated through written primary records and historical texts.

This presentation will introduce how my project will delve into the alternatives to Christian burial available for families of unbaptised infants across England; including non-traditional burial forms and the sale of foetal remains to anatomy schools, with the aim of presenting a social and cultural understanding of foetal and perinatal death during the Industrialisation of England.

6 LANDSCAPES OF BAPTISM: CHILDREN’S BURIAL GROUNDS (CILLÍNÍ) AND HOLY WELLS IN IRELAND

**Abstract author(s):** Murphy, Eileen - Donnelly, Colm (Queen’s University Belfast)

**Abstract format:** Oral

Cillíní (children’s burial grounds) are a recognised class of Irish archaeological monument that were used for the interment of unbaptised infants and others not permitted burial in consecrated ground due to the teachings of the Roman Catholic Church. The archaeological evidence suggests that these sites proliferated from the 17th century and can be linked to the efforts of the Counter Reformation in Ireland, and a re-affirmation of the strict teachings on the need for baptism expounded by St Augustine of Hippo. At least 1600 of these poignant sites have been recorded across Ireland and they occur at a diverse range of locations, including natural landmarks, archaeological monuments, and abandoned Medieval ecclesiastical sites. The latter locations can be explained as a symbol of the hope of the bereaved families that burial in a formerly holy site would confer a degree of sanctity on the dead. The evidence for the relationship between cillíní and the island’s 3,211 recorded holy wells (also used by Catholics during this period) has not been previously explored. To what extent, however, do we find a juxtapositioning of holy wells – associated with baptism – with cillíní – associated with the unbaptised? The paper examines the level of evidence for such an association through a study of the sites in three Irish counties – Clare, Cork and Donegal.

7 THE UNBAPTISED IN THE ARCHAEOLOGICAL LANDSCAPE: FINDING AND RECORDING IRELAND’S CILLÍNÍ (CHILDREN’S BURIAL GROUNDS) USING GIS

**Abstract author(s):** Mundt, Courtney (Queen’s Univeristy Belfast)

**Abstract format:** Oral

The term cillíní refers to the unconsecrated burial grounds used primarily for unbaptised and stillborn children from the late medieval into the early modern period in Ireland. There are over 1,400 cillíní

recorded across the island, with the highest concentration (957) on the west coast. Cillíní are often associated with a variety of archaeological and natural sites. Perhaps due to their more modern usage or because of the sensitivity of the subject, these archaeological sites are not as well studied and analysed as other archaeological monuments in Ireland, particularly when it comes to understanding their relationship with the surrounding landscape. Less than a handful of researchers have mapped cillíní, with most of them either studying their general locations or focusing on one specific county (e.g. Galway and Kerry). Previous studies have focused primarily on how these monuments relate to other archaeological monuments and anthropogenic boundaries, with their relationship to natural landscape features (e.g. rivers, lakes, boglands), underlying soil, geology or topography studied to a lesser extent. This lack of knowledge could negatively affect the preservation and recording of cillíní, and it was with this in mind that a landscape study of County Mayo, which has the third largest amount of recorded cillíní (211) was undertaken. The presentation will provide an overview of the research and discuss how the findings will be used in further cillíní research to raise the profile of these poignant monuments and help ensure their identification and preservation for future generations.

8 **AN EARLY CHRISTIAN CHURCH, MARTYRIUM AND BAPTISTERIUM AT HORVAT MIDRAS, ISRAEL**

**Abstract author(s):** Zissu, Boaz (Bar-Ilan University)

**Abstract format:** Oral

Horvat Midras is located in the Judean Foothills, ca. 6 kms NE of Bet Guvrin – Eleutheropolis, and ca. 40 kms SW of Jerusalem. The church was erected in the 4th century CE in the centre of the ancient site. Earlier layers, found underneath its floor, and dated to the Early Roman period were destroyed during the Second Jewish Revolt (132-136 CE). After a hiatus during the 2nd and 3rd centuries CE, the vestiges of the earlier buildings were levelled, and a new basilical structure, paved with a white mosaic floor was erected. Its construction, in the 4th century CE, was associated with a venerated tomb, perhaps the *raison d’être* of the complex. This tomb was initially an underground ritual bath (mikveh) serving the 1st-2nd c. CE Jewish settlement, repurposed into a burial chamber during the 4th century CE. In the next stage, a basilical church adorned with marble columns, capitals and multicolored mosaic floors was erected. The church was built within the former basilical structure and reused some of its architectural elements. The apse was built just above the burial chamber – apparently showing that this tomb inspired the construction of the church. We identified at least two architectural stages in this church, both paved with multicoloured mosaic floors; the second was marked by the construction of a room housing a baptismal font, above the stepped corridor of the venerated tomb. Because this room laid above and permitted access to the venerated tomb, it was termed a “martyrium”. This stage is dated to the third quarter of the 6th century CE and the structure remained in use until an earthquake in 749 CE. The lecture will present this architectural complex, its stages and formation, focusing on the martyrium and baptisterium.

9 **ARCHAEOLOGY OF INITIATION: EARLY BAPTISMAL FONTS IN MEDIEVAL ENGLAND**

**Abstract author(s):** Twomey, Carolyn (St Lawrence University)

**Abstract format:** Oral

The material culture of Christian baptism has influenced the performance and interpretation of the rite of initiation since the days of the late antique Church. Unlike continental contexts, the islands of Britain and Ireland do not share the rich history of baptistery building familiar to Christian contemporaries in Mediterranean regions. The Insular world is a fascinating region in which to examine the development of other diverse forms of baptism prior to the standardization of the baptismal font form in the eleventh and twelfth centuries. Some early fonts in England (e.g. Wilne, Melbury Bubb, Dolton, etc) bear figural and zoomorphic decoration from their former lives as standing crosses, a recycling that has challenged both church and art historians. This paper reconsiders these early fonts by integrating them into the broader history of baptismal sculpture and iconography from Wales, Scandinavia, and Frankia to elucidate the local and European contexts for font production at this time before a universal experience of the rite of initiation. This archaeological, historical, and art historical approach challenges traditional explanations for the origins of stone baptismal fonts that root this material change in the development of sacramental theology in twelfth-century Paris. Focusing on the act of re-use, I show how standing cross fragments were purposefully adapted for baptism due to the monumental meanings of their original ‘living stones.’

440 **‘TOUCHING OBJECTS, FEELING MATERIALS’: MATERIAL TRANSFORMATIONS, TECHNOLOGY AND SENSORIALITY IN ANCIENT MATERIAL CULTURE**

**Theme:** 6. Material culture studies and societies

**Organisers:** Perna, Simona (Institut Català d’Arqueologia Clàssica - ICAC) - Di Febo, Roberta (Universitat Autònoma de Barcelona - UAB; Institut Català d’Arqueologia Clàssica - ICAC) - Casas, Lluís (Departament de Geologia, Universitat Autònoma de Barcelona - UAB)

**Format:** Discussion session

Material culture studies have progressively become immaterial. Matter is the core of material culture and by neglecting artefacts’ constituent materials, the gap between these, the material world and, eventually, the human component risks being amplified. We aim to fill this gap by putting forward an interdisciplinary debate which starting from objects’ materials seeks to combine the latest

analytical methods with socio-anthropological and experimental approaches to understand how materials were ‘transformed’ into artefacts in the past and the effects these had on people – makers, users and alike.

Broadly inspired by Ingold’s idea that materials ‘flow mix and mutate’ (2007:14), this session seeks to explore ancient artefacts from the perspective of their material properties, qualities and possibilities (Ingold 2013) to better understand objects’ uses and productions through their affordances (Gibson 1976) and ‘sensorial assemblages’ (Hamilakis 2017). Papers will address research and scientific (e.g. archaeometric, experimental) analyses on object materials by considering one or more of the following aspects: material properties, origins, sourcing and environmental impact (e.g. from access and procurement to pollution); the technical expertise and technological innovation behind the transformation and manipulation of the materials (including reuse and recycling or by-products) and value attribution; conservation and reception in later periods; sensoriality or sensory awareness: how materials were sensed (colour, texture, feel, smell) by people and how this impacted artefact creation, design and meaning especially in relation to intended use, contexts or landscapes. We intend to cover multiple media and forms of material culture from the Greco-Roman world, although earlier or later periods are welcome.

Analysing material culture from its ‘inside’ has the potential to provide deeper insight into objects’ affordances and people responses. With such a perspective, our aim is to widen the horizon of material culture studies by bringing the material component back into it.

**ABSTRACTS:**

1 **TESTING THE POSSIBLE FUNCTIONS OF THE UNIO SP. VALVE IN THE HAMANGIA CULTURE (MILL. V CAL BC)**

**Abstract author(s):** Margarit, Monica (Valahia University of Targoviste; “Vasile Parvan” Institute of Archaeology, Romanian Academy) - Radu, Valentin (National Museum of Romanian History) - Voinea, Valentina (Museum of National History and Archaeology Constanta)

**Abstract format:** Oral

In this study we discuss the possible uses of the Unio valves by the Eneolithic communities from Cheia (southeast Romania, 5th millennium cal BC). The assemblage consisted of 225 valves, of which 101 valves exhibited various use-wear marks.

The methodology used relied on both macroscopic and microscopic analysis of the use-wear marks present on the archaeological artefacts, supplemented by experimental data. The pattern of the use-wear development, including the deformation of the original volume and the removal of the external structure of the valves was systematically analysed. Our experimental project covered various aspects such as identifying the means of gathering/obtaining the raw materials, the times required for each operation in the technological chain, and the materials processed (e.g. wood, skin, clay, fish and bone). All these parameters were precisely recorded in our database.

The results indicated that: 1.) the manner these materials were sensed - they could be easily held in the hand and manipulated - did not require important technological modifications, e.g. retouching was not necessary because the edge morphology of the valves was already optimal for carrying out a large range of activities. 2.) among the various experiments, the one focusing on the surface treatment of dry clay vessels yielded marks most similar to the ones present on the archaeological artefacts.

The Cheia assemblage provides a good example of a community turning certain raw materials into tools, without any technological investment. They knew exactly where to find and collect them from and simply exploited their natural characteristics.

Acknowledgments. The work presented here was supported by the grant of the Romanian Ministry of Education and Research, CCCDI - UEFISCDI, project number PN-III-P2-2.1-PED-2019-1279, within PNCDI III and by the grant from the Recurring Donors Fund of the Romanian Academy managed by the Patrimoniul Foundation (project no. GAR-UM-2019-II-2.1-1/15.10.2019).

2 **BRONZE IN THE IRON AGE: VARIATIONS IN FE IN ITALIAN BRONZE ARMOUR C. 400 BCE**

**Abstract author(s):** Armstrong, Jeremy - McAlister, Andrew - Emmitt, Joshua (University of Auckland)

**Abstract format:** Oral

This paper will present new pXRF data on bronze military equipment finds from across the Italian peninsula dating to the period c. 800 to c. 300 BCE. Data were acquired on 40 objects in 2019, and are here coupled with historical pXRF data as well as stylistic and visual analysis of a wider set of items. We argue that there is a growing body of evidence supporting the introduction of a new type of copper alloy c. 400 BCE in Italy which featured slightly higher levels of Fe and which was associated with new production techniques. The appearance of this relatively high-Fe alloy runs against the general trend towards less Fe in bronze in produced in Italy, seen in the preceding centuries, and has so far been found only in particular types of pieces which were produced through casting. The high-Fe military equipment is also associated with new forms of armour and featured fundamentally different physical characteristics to previously produced bronze military equipment. We will contextualize this data within the wider picture of bronze armour production during this period and discuss how the use of the proposed new alloy would have altered the associated industries, changing the nature and experience of bronze military equipment production. Both time and the available data currently preclude a detailed discussion of the materiality/sensoriality of these items for their end users, although some initial suggestions, based on ongoing experimental work, will be offered.

3

THE MATERIALS OF LIGHT: OBSIDIAN ‘MIRRORS’ IN THE HOUSES OF POMPEII

**Abstract author(s):** Anguissola, Anna (University of Pisa)

**Abstract format:** Oral

A small set of slabs made of dark stone (likely obsidian) have been recovered from the houses of Roman Pompeii. There, panels of a dark stone were typically included in black painted walls and surrounded by painted frames as ‘mirrors’. Notwithstanding the wealth of information about the Roman knowledge, use, and interest in obsidian and other dark stones as part of domestic displays, the evidence from Pompeii is unparalleled in other sites and areas of the Roman world. The black panels from Pompeii all belong to mid-first century C.E. contexts, as part of elaborate decorative systems including different materials (black stones, marble, gold, pumice, plaster) and colors. The paper explores the function and meaning of these artefacts in light of the Roman discourse on matters and their qualities, both physical and ethical. In particular, the paper argues that the owners and decorators of the houses of Pompeii chose these pieces in light of both their exotic flavor and, more importantly, of their potential to stage a network of sensual similarities and contrasts to a variety of other materials and techniques (such as water, marble, silver, gold, and wall plaster). The argument relies on the results of a campaign of on-site study of the evidence, including characterization of the panels by means of both Raman Spectroscopy and Portable X-ray Fluorescence (pXRF). By assessing the identity of the stones, their provenance, and the production techniques used to cut, shape, and polish them, this research provides the first full account for the supply, technologies, sensual appreciation, and meanings of obsidian and (optically) related materials in the Roman antiquity.

4

INSIDE THE GLASS CRAFTSPERSON MIND: MAKING OF ROMANO-BRITISH GLASS BANGLES

**Abstract author(s):** Ivleva, Tatiana (Newcastle University)

**Abstract format:** Oral

The main aim of the paper is ‘to bring the makers out of the shadows and to celebrate the creativity of their achievements’ (Ingold 2013, 22). The case-study concerns Romano-British glass bangles, seamless ring-shaped adornments made of coloured glass. Glass bangles appeared in Britain in the mid first century AD, coinciding with the Roman conquest of the southern regions of England. Prior to the Roman invasion, Britain had no history of seamless glass bangle production, although on the Continent glass bangles had been in circulation already for two and half centuries. Various ethnographic studies have provided clues to how a glass bangle can be made seamlessly. The information from these studies was used by a French team that tried to replicate Late Iron Age glass bangles by following a number of the techniques currently known. In this paper, the author has worked with an experienced glass artisan, who was commissioned to make replicas of Romano-British glass bangles. The questions addressed were: a) what does the maker of a replica of an archaeological artefact have to stay about how he experienced the production of a glass bangle; and b) as the craftsman had never before produced a seamless glass bangle and only attempted it with the author’s guidance, how might his experience inform us about training of craftspeople and the craft development in Roman Britain?

5

SILK TEXTILES FROM PALMYRA: MATERIAL IMPORTATION TO TECHNOLOGICAL INNOVATION

**Abstract author(s):** Zhou, Junjie (LMU Munich)

**Abstract format:** Oral

Roman Palmyra was not only a hub of cultural transmission but also a hotbed of integration and creation. In the field of textile archaeology, Palmyra preserved one of the largest collections in the Graeco-Roman world, among which ca. 100 fabrics made from Chinese silk survived. This paper aims to analyze how the unique properties of silk were appreciated by the Palmyrene, adapted to their local costumes, and eventually led to a new technique of damask weaving during the first two centuries CE. I shall first briefly introduce silk production in China, its material qualities, and its identification under the Scanning Electron Microscopy. Then different categories of silk textiles from Palmyra will be examined to differentiate between Chinese imports and local products. Finally, the technological development will be traced of how the imported “Han-damask” evolved into the innovative 3-1/1-3 damask weaving. Through the specific case study of silk textiles from Palmyra, this paper hopes to reflect on a broader picture of how the material transformation was embedded in the technological evolution and how it contributed to the “weaving” of the material culture.

6

A PAIR OF STOCKINGS? MATERIALS, CRAFTS METHODS AND USEFULNESS IN PRE-MODERN BURIAL FOOTWEAR

**Abstract author(s):** Ruhl, Erika (SUNY at Buffalo)

**Abstract format:** Oral

Burial clothing in northern Finland between the 17th and 19th centuries can be broken into two categories: (1) re-purposed items, used first in life later as burial clothes, and (2) re-made items, crafted from second-hand materials specifically for burial. Some items, like burial robes, are constantly re-made, while other categories, such as the stockings, contain both re-made and re-purposed items; the focus here will be on the stockings.

This dichotomy introduces an overarching question: Were these stockings comfortable? This question is considered in the context of two specific performance characteristics: whether the items were warm, and were they well-fitted? Although both categories are present in burial clothing, re-purposed items retain features that made them warm, well-fitted, and thus comfortable in life, while

re-made items are often hastily assembled from less-suitable materials, and lack these performance characteristics. As such, this paper explores what it means to provide for the dead on symbolic and practical levels.

Based in Design Theory and Material and Technological Choice, these stockings are analyzed “from the ground up,” starting with the materials selected, through the crafting methods, and stockings’ resulting performance characteristics. The materials range from knit silks and wools to woven bast fibers; some are clearly hand-crafted, while others tell very different tales about the impacts of industrialization and handcrafting professionalism on textile materials; in contrast, several re-made stockings are stitched from woven bast fibers. This in turn introduces questions about the experience of creating, using, re-using, and finally interring these materials.

7

ARUNDO DONAX: REINSTATING A NEGLECTED MATERIAL IN CLASSICAL ANTIQUITY

**Abstract author(s):** Foxhall, Lin (University of Liverpool)

**Abstract format:** Oral

One of the great difficulties of studying the material world of classical antiquity (or indeed any ancient period) is that as archaeologists we may overestimate the importance of the imperishable material remains that we possess, neglecting the potentially even greater significance of perishable materials in the practices and sensorial experiences of everyday lives. This paper focuses on one incredibly versatile material resource, reeds, notably the giant reed, *Arundo donax*. This is a common plant which grows abundantly in coastal areas and wetlands across the Mediterranean, even in areas which are semi-arid. Never deliberately cultivated (though probably sometimes managed), it was ubiquitously exploited to create an enormous range of different kinds of objects (including tools to make other objects). Its properties of strength, sharpness, flexibility and durability, as well as its easy accessibility for many people, were key to its versatility. I will investigate the ways in which the physical properties of *Arundo donax* shaped both the choices and sensory experiences of the makers and users of things. I will also explore the numerous ways that this plant was entangled with human lives in classical antiquity, advocating the need to reinstate it to a central position in our reconstructions of ancient material worlds.

8

SENSORY ENGAGEMENTS WITH HOUSEHOLD POTTERY IN LBA CYPRUS

**Abstract author(s):** Steel, Louise (University of Wales Trinity Saint David)

**Abstract format:** Oral

This paper explores people’s daily sensorial engagement with pottery in LBA Cyprus, both production and consumption. The focus is on embodied encounters with kitchen equipment – the Plain ware pots, pans, basins and pithoi – used on a daily basis in the production and consumption of food and drink. Although Plain ware typically comprises the greater part of a Late Cypriot ceramic assemblage, this class of pottery tends to be overshadowed by the more visually appealing tableware – White Slip and Base Ring – even though these have a more restricted distribution within settlement contexts. Nonetheless, I would argue that for most Cypriots in the LBA, daily material engagements with pottery were primarily mediated through Plain ware. The focus on this paper is a discrete group of vessels excavated in storerooms in Building 1 at Arediou, a space apparently associated with processing and consumption of foodstuffs at an extra-household level. This paper considers the capacities (agency and vitality) of the clays used to make these vessels and how these enabled or constrained the actions of the potters who created them; similarly, it examines the interaction and the experiences of people working with pottery on a daily basis within the settlement. Focusing on material engagements and the myriad intersections between human and non-human; allows us to think about the materiality of the Late Cypriot social world and specifically the tactile experiences involved in working with pottery.

9

THE MANIFOLD MATERIALITIES OF ARCHAIC GREEK CULT STATUES

**Abstract author(s):** Martin, Daphne (University of Cambridge)

**Abstract format:** Oral

This paper explores the range and variety of materialities that constitute archaic cult statues, as well as their sensorial impact on the sanctuary visitor. Made of ivory, gold, wood, and stone, with inlays of precious materials and intricately embroidered textiles, I consider how the statues’ sacrality is embodied in and expressed through their composite and multi-medial nature.

I focus first on the chryselephantine statues from the Halos deposit, found in a votive trench under the Sacred Way at Delphi in 1939. These are commonly identified by scholars as Apollo and Artemis. With faces and limbs made of luxurious ivory, and hair, jewelry, and clothing appliqués made of thin sheets of hammered gold, these statues would have overwhelmed the viewer by their sheer sensorial splendor. Through analysis of the properties of the individual materials, and then their overall effect (and affect), this paper re-constructs the visual and sensorial power of the cult statues through the lens of their composite materiality.

I then go on to consider another material, cloth, through two cult statues for which we have evidence for textile dedication: Athena Polias at Athens and Apollo at Amyklai (Vlachou 2017). By considering both the sacrosanct process of weaving and the religious festivals in which such objects were dedicated, this study identifies textiles’ particular religious affordance in the link between the human hands which would have woven and carried the textiles, and the cult statues for which they were made.

In considering the materiality of archaic cult statues, this paper aims to bring into focus the myriad ways in which material would have mediated the visual and haptic experience of divinity in the ancient Greek sanctuary context.

MOSAIC AS SENSORIUM: A HAPTIC APPROACH TO THE PAVEMENTS OF ANTIOCH

**Abstract author(s):** Miranda, Amy (Aarhus University)

**Abstract format:** Oral

Mosaic floors are walked upon and not necessarily viewed through direct vision. Rather, they are viewed through peripheral vision (which Juhani Pallasmaa convincingly attributes to the haptic sense), not quite in focus, but crucially completing a space. The twitches and undulations of floor mosaics are experienced somewhat visually, but also haptically. With the haptic, mosaics deeply affect an individual through the illusionistic dimensions of a mosaic surface that I suggest create a topographical map that delineate the floor and describe the space. This is perhaps most readily demonstrated through the ornamental and material components of mosaic pavements which, I suggest, unite compositions to create a holistic surface. As a case study, I look to some of the mosaics from ancient Antioch in present-day Antakya, Turkey. Dating to the second and third centuries CE, these pavements are a testament to how decoration connects with individuals through its sensorial potentials, which contribute to a synaesthetic pleasure. The houses of Antioch, with their mixing of figural and ornamental motifs, are then developed as sensuous, synaesthetic spaces through experiences of materiality and color. The stone and glass tesserae play with texture and weight as well as the effects of light to go beyond what can be seen. I draw upon recent work in architecture and geography on space and texture (Pallasmaa, as well as Kevin Hetherington and Mark Paterson) and suggest an investigation into the tactility of the tesserae’s material (stone and glass) and hapticity of the floor surface. The synaesthetic topography an individual travels through as one steps upon the floor contributes to the surface’s allure. The materiality of mosaics, the physicality of the tesserae, their colors and reflections, draw particular attention to how architecture functions beyond the visual as they act with the haptic and other senses to build an immersive environment.

SENSING WHAT CANNOT BE SEEN: ENGRAVED GEMS AND DIVINE REPRESENTATION

**Abstract author(s):** Allen, Ruth (Michael C. Carlos Museum, Emory University)

**Abstract format:** Oral

Engraved gemstones have long been considered too small, too frivolous, and too luxurious to be considered much more than beautiful, and remain largely absent from accounts of ancient Mediterranean visual culture, or else are sidelined as ancillary to the study of monumental art. But even those scholars who have understood gems’ potential have given them little meaningful agency beyond their capacity to stamp: engraved gems are, by and large, seen only as tools for sealing, and their images consequently given more importance in impression than on the stone. This paper aims instead to take gems seriously as objects whose material qualities – their colour, shine, and “touch-capacity” – were as integral to their function as their iconography, recognising that engraved gems were used, adored, and examined as decorative objects seen and worn on the body, and bringing ‘ornamental’ gems into conversation with those typically classed separately as ‘magical’ or amuletic.

Its focus will be on the relationship between gems and the divine. We will look at the use of gems in the adornment of cult-statues, and the ways in which the special material qualities of the stone played an important part in the performance of divine presence. We will then explore how the engravers of gemstones exploited these material associations, promoting the sensual as much as the visual in order to turn engraved gems into miniature sites of divine encounter. In so doing, this paper aims to show the ways in which the agency of the gem-image was enhanced by the material and aesthetic qualities of the stone and animated by the act of wearing, which created further meaning in the tensions between seeing and not seeing, looking and handling, intimacy of scale and the flashy, look-at-me brilliance of the stone.

THE MATERIAL LIFE OF LINEAR A: A STUDY OF OBJECTS BEARING AN UNDECIPHERED SCRIPT FROM MINOAN CRETE (C.1800-1450 BC)

**Abstract author(s):** Rice, Mnemosyne (Trinity College Dublin)

**Abstract format:** Oral

Objects bearing Linear A inscriptions are not merely textual documents; they are material objects which are transformed by the addition of writing, mutually entangling text and material. This paper aims to understand this underexplored relationship, and how Linear A text contributed to the multiple meanings of objects through two case studies: 1) the stone vessels or ‘libation tables’ found in ritual deposits and 2) the clay (administrative) tablets found in the palaces. These examples showcase the spectrum of affordances which inscribed artefacts offer.

Some of the stone vessels appear to have been designed to receive inscriptions, while the clay tablets are thought to be palimpsests; these differences in engagement with Linear A are dependent on material properties, but more importantly, are the result of deliberate choices made by their creators. Stone vessels had potentially very long use-lives and human agents interacted with them in multiple contexts (from production to religious events), suggesting a multiplicity of sensorial experiences. Because clay tablets are interpreted as ‘reusable’ records which could be erased and reinscribed, the sensorial ‘moments’ would have happened more frequently and over shorter periods. In both cases, the materials (various types of stone and clay) and their accompanying text would have evoked multiple, simultaneous meanings for their human interlocutors.

This paper draws on Piquette and Whitehouse’s (2013) framework for analysing ‘graphical artefacts’, and studying their production as a craft. This approach reveals the inscription of objects as a crucial step in the production process. It also foregrounds the human agents responsible for creating the artefacts, and their requisite knowledge and experiences (e.g. knowledge of materials’ proper-

ties, skill in specialised tool use, and varying levels of literacy). Through detailed analyses of the inscriptions and their interaction with the whole, this paper reassesses Linear A graphical artefacts from a material perspective.

WATER, ARCHITECTURE, AND THE SENSES: EXPLORING THE MATERIALITY OF AQUATIC LANDSCAPES IN THE ROMAN WORLD

**Abstract author(s):** Rogers, Dylan (University of Virginia)

**Abstract format:** Oral

The Roman world was full of water in various contexts, from splashy fountains, to immersive bathing complexes, to underground drainage networks. Water-displays, though, afford us with an important avenue of inquiry into the nature of sensory experience in Roman society, both in private and domestic contexts, as we can piece together ancient reactions to the multisensory pleasure of flowing water attested through literary and archaeological evidence. This paper, thus, explores how we can consider how water had the ability to oftentimes drastically alter the built environment in a variety of spaces in the Roman world. In sensory archaeology, by using the framework of the sensorial assemblage (or sensory field), which considers the built environment, substances, artifacts, and memories, we can begin to understand the reason behind fountain construction, as it had the ability to change the experience of a space and create new memories for ancient Romans. Because water, especially moving water, is inherently ephemeral, structures built to harness this element are interesting case-studies for reconstructing past sensory experiences. As such, if we consider the materiality that is inherent in water, we can reimagine these spaces—along with repopulating them with ancient Romans. An important aspect of this research is how, despite geographical location and climate zone, there was a propensity across the Roman empire to display water—which helped forge a common Roman sense of identity—that, in a way, was intimately tied to the senses themselves. This paper will consider a few examples of water-displays from the Roman world, especially those found at the site of Jerash (modern Jordan), in order to elucidate the sensorial impact of water throughout various Roman landscapes.

BRIGHTNESS - ΣΙΓΑΛΟΕΙΣ - SENSED AND ITS TRANSFORMED METAPHORICAL FUNCTION WITHIN HOMERIC POETRY

**Abstract author(s):** Saito, Yukiko (University of Liverpool / Kyoto Seika University)

**Abstract format:** Oral

This paper, focusing on the use of σιγαλόεις (bright, shining), pursues two aims. First, distilling the subtle, unseen nexus between colour/light, touch, and motion. Second, elucidating how viewers’ sensory experiences might be affected by colour or its bright-hued aspects, through cognitive exploration. Brightness encompasses human life itself. How can the sense or aspects of brightness associated with materials be most effectively delineated? Characters are portrayed as being amazed (θεάομαι; Od. 19. 229 and 235) on seeing Odysseus’ bright appearance. So are we, i.e., viewers. Odysseus wears a shining tunic with the sheen of dry onion-skin, which shines radiantly as the sun shines (Od. 19. 231-233). Σιγαλόεις is used in describing various materials such as when Andromache discards her shining headdress (Il. 22. 468), Nestor takes up shining reins (Il. 8. 116), Penelope enters the bright upper chamber (Od. 16. 449), and so forth. They illuminate the intriguing nature of brightness. Its religious significance was profound for society in antiquity (e.g., Parisinou (2002); Christopoulos, Karakantza and Levaniouk (eds.) 2010; Platt 2011). Viewers, ourselves included, seem to be always attracted to bright light and gaze in wonder at it. I should like to go one step further, to discern the deeper aspect of visualising brightly-coloured scenes as multisensory experiences (e.g., Hölscher 2018; Witcombe 2018; Butler and Bradley (eds.) 2019). Examining how various σιγαλόεις-related scenes are associated with each other, I investigate what kind of function(s) those shining materials could be seen to be performing, while seeking σιγαλόεις’ metaphorical, transformed representation. Spotlighting σιγαλόεις, whose materials indicate the radiant colour-hue’s effect on viewers’ recognition, my goal is to unveil the poet’s aesthetical skill in composing his story, like the textual sounds of a unified, harmonious ensemble. Then the social significance of the realisation of ancient colour-sense is unfolded, accordingly.

THE ARCHAEOLOGY OF COASTAL COMMUNITIES

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Wouters, Barbora (Vrije Universiteit Brussel) - Hansen, Gitte (University Museum of Bergen) - Lo Russo, Sarah (Vrije Universiteit Brussel; University of Basel)

**Format:** Regular session

Coastal zones, including riverine estuaries, have always constituted contact zones where people connected and interacted, thereby exchanging thoughts and goods. This connectivity as well as the dynamic coastal environment made these communities highly responsive to change and innovations. People continuously adapted to new situations and influences (trade, migration, climate, sea-level rise...), which stimulated the social resilience and the adaptation of changes in lifestyles. Both are embodied in the material features of the coastal landscape and its landing and meeting places, which acted as hubs for trade and ideas. Different authors, including Gordon-Childe, have in the past addressed the evolution of these centres and the related issue of urbanisation. We approach this question of connectivity from different angles: the study of the exchange of artefacts, the changing environment and use of space, all the way to the environmental archaeology of the coastal communities. This session wants to further explore the responses to this dynamic connectivity by focusing on the archaeology of the landing and meeting places from a variety of regions

and periods, not limited to urban settlements. We invite contributions spanning different sub-specialisms of archaeology, including studies presenting new findings, theoretical or scientific advances or applications.

ABSTRACTS:

1 THE CHANGING ENVIRONMENT OF TYRRHENIAN COAST AND THE CHANGING FORTUNE OF LANDING PLACES OVER TIME

**Abstract author(s):** Citter, Carlo (University of Siena)

**Abstract format:** Oral

The Tyrrhenian coast between Rome and Pisa has changed much over time. The major rivers (Tevere, Ombrone and Arno) used to shape it together with sea level fluctuations. When dealing with landings and main harbours in this region, we need to reconstruct the most likely scenario of the period we are studying. Most areas that look as fertile plains today, used to be lagoons for the whole antiquity. Thus, providing opportunities for inner, safer landings. But they turned to marshes in modern era. The recorded changes contribute to understand the trajectory of many settlements, including riverine towns, harbours, market-places. Of course, the changing fortune of these settlements cannot be caused only by environmental changes. But they impacted much and recent literature acknowledges this as one of the main causes. We will provide an overview on the long durée because some major Etruscan sites declined in the Roman period, others persisted until the early middle ages. Only a few proved to be resilient over time.

2 HUMAN-ENVIRONMENT INTERACTIONS IN NORTHERN DENMARK DURING 3000 YEARS OF COASTAL AND RESOURCE CHANGES

**Abstract author(s):** Kristiansen, Søren - Ljungberg, Thomas (Department of Geoscience, Aarhus University) - Christiansen, Torben (The Historical Museum of Northern Jutland) - Dalsgaard, Kristian (Department of Geoscience, Aarhus University) - Haue, Niels (The Historical Museum of Northern Jutland) - Greve, Mogens (Department of Agroecology, Aarhus University) - Nielsen, Bjarne (Vesthimmerlands Museum)

**Abstract format:** Oral

New refined understanding of the global relative sea level (RSL) has contributed to much more precise estimates of the rates of the paleo-coast change worldwide. This rapidly evolving understanding therefore holds major potential in relation to onshore human-environment interaction studies at local and region levels. However, changes of coastlines and their consequences for prehistoric societies living in glacio-isostatically uplifting areas have not been assessed on a larger scale and based on high-precision modelling of the slow changes of the coastal ecosystems as meadows, marshes and lagoons.

In this paper we present new results which highlights how high-resolution models of coastal and settlement development during the last 3000 years in the central Limfjord area (Northern Denmark) are correlated with archaeological evidence. The methods include optically stimulated luminescence (OSL), geo-archaeology, correlation with archaeological databases, and upscaling using paleo-landscape modelling and remote sensing (lidar) data.

This new temporal and spatial model of coastal development shows that only few of the new land areas were colonized, and only for a short period during the Late Roman Iron Age until 400 CE. Although the new marine forelands constituted rich grassing lands, Bronze and Iron Age settlement locations were little influenced by the steady growth of these. In addition to improving the understanding of the current archaeological record, the high-resolution model may serve as an important base for qualification of future research and for monitoring and protecting archeological sites in the region. Combined, this provides new knowledge of relevance for both the paleo-environment changes and the humans living along the ever changing coasts.

3 A HUNDRED DIFFERENT WAYS TO THE BEACH: WHY THE PATH TO THE SHORE MAY BE MORE SIGNIFICANT THAN YOU THINK

**Abstract author(s):** Johnson, Andrew (Manx National Heritage)

**Abstract format:** Oral

The Isle of Man has a varied coastline extending 160km and ranging from wide, open beaches, through small coves and rivermouths, to impenetrable cliffs. Today the island is served by seven small ports and harbours, but these represent just a tiny proportion of the landing places historically used by a once largely rural population.

Today the islanders take access to the shore for granted, but the routes by which they reach the coast, and the reasons for their existence, go largely unregarded. The physical character and legal status of these routes are often significant in betraying their former purpose: some exist as footpaths, some as tracks leading only as far as the nearest farmstead, whilst others have been transformed into public highways.

Perhaps even less appreciated is the extent to which the shore, both intertidal and above the strand-line, has been adapted or altered to improve safety or ease of use. It is sometimes possible to glean from this the reasons individual landing places were exploited: fishing and the collection of seaweed as manure are amongst the most obvious uses.

4 2500 YEARS OF HUMAN INTERACTION WITH THE SHORELINE AT TRONDHEIM, NORWAY

**Abstract author(s):** Cadamarteri, Julian (NIKU - Norwegian Institute for Cultural Heritage Research)

**Abstract format:** Oral

This paper presents and discusses data relating to settlement and natural topography derived from archaeological excavations in the medieval town of Trondheim, Norway. Trondheim is situated at the estuary of the river Nid and is the northernmost medieval city in Norway, growing from a small Viking Age regional and inter-regional coastal trading centre established during the 10th century AD. As such it played an important part in Norwegian history and was the seat of the Norwegian kings until 1217. And the seat of the Norwegian archbishop until 1537. Recent archaeological finds document the presence of an agrarian settlement here since the early Pre-Roman Iron Age at c. 500 BC. Throughout this long period, the local population lived in a changing natural environment created by ongoing interrelated formation processes, including isostatic recovery, alluvial deposition and a landslide which covered part of the peninsula with a thick body of clay. The archaeological material show that the peninsula and especially the shore seem to have been used for gatherings dating back to the first century AD. The settlement established in the 10th century was also located near the shore and a medieval Thing, a law assembly, was regularly held on the beaches. The archaeological material demonstrate the close interaction of natural processes and human actors in the formation and use of the landscape. The dynamics of human settlement practices in the context of the natural environment, both terrestrial and marine, are highlighted. The settlement history is discussed in the wider context of local and regional developments during the Norwegian Iron Age.

5 THE OLD “BAYE DE BRETAGNE”: A MARITIME CULTURAL LANDSCAPE OF ATLANTIC FRENCH COAST

**Abstract author(s):** Gaele, Dieulefet (UMR CRéAAH-LARA, Université de Nantes) - Pouzet, Pierre (UMR 6564 LETG, Université de Nantes)

**Abstract format:** Oral

This research deploys an maritime and coastal approach, combining archeology and marine geosciences on the old “Baye de Bretagne” localised in Loire-Atlantique (France). In medieval and modern times, this bay was an important salt supply center for merchants and fishermen in Northern Europe, then a large anchorage linked to Nantes and to the maritime route between Saint-Malo, Lorient and La Rochelle. But, at the end of the medieval period, the evolution of the environment and the use of space conditions the reorganization of nautical and maritime activity. And now, what are the archaeological markers of this activity on land and under the sea? And what can they teach us about the resilience of coastal populations?

The oceanic coastal societies of the past have succeeded in exploiting resources, creating port facilities and navigation techniques for their growth by seizing the coastline and adapting to changing constraints. They thus produced a “maritime cultural landscape”. The Land-Sea continuum has become a vast and complex maritime network with urban, port and artisanal areas interconnected with maritime routes. The challenge of this proposal is therefore to indentify the construction and evolution of the maritime landscape.

6 HUMAN ADAPTATION TO LAKE LEVEL CHANGES IN THE LATE-HOLOCENE: KURSI BEACH AS AN EXAMPLE (SEA OF GALILEE, ISRAEL)

**Abstract author(s):** Giaime, Matthieu (Hatter Laboratory, Recanati Institute for Maritime Studies, Department of Maritime Civilizations, University of Haifa; Institut de Ciència i Tecnologia Ambientals - Universitat Autònoma de Barcelona) - Artzy, Michal - Cohen, Haim (Hatter Laboratory, Recanati Institute for Maritime Studies, Department of Maritime Civilizations, University of Haifa)

**Abstract format:** Oral

During the Holocene, the Jordan Valley was a cradle of human occupation where the emergence of the first complex societies was noted. Local populations benefited from a particularly favourable environment, fertile agricultural lands and plentiful of water from the Jordan River. Along the valley, the freshwater lakes attracted local inhabitants to their shorelines and they, in turn, closely interacted with their natural environment. These anthropogenic legacies, modified over the millennia constitute the cultural heritage of the region. Lake of Galilee/Kinneret’s ancient coastal settlements have kept international interests due to the Christian world concern as the area where Jesus performed several miracles.

Using geomorphological and archaeological indicators, we aim to highlight the importance of Galilee lake level changes during the Late-Holocene period. Several structures excavated at Kursi Beach – including a breakwater and fishponds – dated to between the Iron Age and the Byzantine period provide evidence of pluri-metric lake level changes during the 1st Millenium BCE and the 1st Millenium CE. Our data is comparable with archaeological indicators originating from other Lake of Galilee excavation sites to better constrain lake level changes during that time period. Understanding lake level changes is of high interest to contextualise archaeological discoveries and to analyse the importance of human adaptation to environmental changes during a key period in this region.

7 DYNAMISM AT THE EDGE: CONNECTIVITY AND ISOLATION IN OILEÁN CHLÉIRE’S SEASCAPE

**Abstract author(s):** Kerr, Sarah (Aarhus University)

**Abstract format:** Oral

This paper introduces the coastal zone of Oileán Chléire (Clear Island), Ireland, and traces its spatial and temporal connectivities that exist in juxtaposition with its cultural and physical isolation. Oileán Chléire is Ireland’s most southerly inhabited island located approximately 13km from the mainland, in a seascape called Roaringwater Bay. In the late-medieval period, the Bay was controlled by the O’Driscolls who built a constellation of twelve tower houses (small castles) along the coast and its islands. On Oileán Chléire they built Dún an Óir tower house, the furthest castle from their centre of activities with architectural anomalies that suggest it was of comparative low status. Heightening the peripheral sense of Dún an Óir is its location on a promontory, facing towards the Atlantic Ocean rather than the Irish mainland. Today, there is a feeling of reaching the edge of Ireland, perpetuated by the promontory inaccessible at high tide.

This narrative is balanced with the evidence for late-medieval connectivities. Further architectural evidence indicates Dún an Óir’s role in connecting Oileán Chléire to Roaringwater Bay, Southern England, and South-West Europe. Furthermore, there is landscape and placename evidence to suggest temporal connectivities. It will be argued that Dún an Óir’s promontory was occupied from the early medieval period and its abandonment in the 17th century should be considered part of a transformation in the island’s connection with further afield, rather than deterioration. Therefore, taking a broader temporal view of Dún an Óir reveals resilience and adaptation in the face of challenges which included battles with the English and pirate raids. The challenges facing Oileán Chléire and Dún an Óir have changed but not ceased: today, both are threatened by storm surges, sea-level rise, and high winds. This paper will close on the local community’s continued resilience, particularly that of the current O’Driscoll clan.

8 PORT COMMUNITIES AND THE TRANSFORMATION OF PORT CITIES AND HARBOURSIDES IN BRISTOL AND COPENHAGEN

**Abstract author(s):** Whatley, Stuart (University of Bristol; University of Cardiff)

**Abstract format:** Oral

Between the years 1400-1700 increased commercialisation, consumption and consumerism had transformed many regions around the globe. The effect of these changes led to urban development, which was especially visible in port cities. Urban excavations at these port cities have revealed consumption of comparable types of goods suggesting similar social and cultural practices occurring within harbourside communities.

In northern and western European coastal cities, this transformation was even more apparent. The harbourside communities were found to comprise an ever-changing array of finds linked to daily life, industry and public eating. This occurred in areas comprising a wide range types of buildings linked to maritime trade, small-scale industry, and the domestic community. Meanwhile, the physical harbour areas were constantly redeveloped to undertake and administer trade, store goods, and enable transport of people.

This talk will use information from case studies of international harboursides at Bristol in England and Copenhagen in Denmark to discuss this information. It will utilise artefactual, structural and built remain evidence alongside environmental remains.

9 DESTRUCTION AS CREATION. LAND DEVELOPMENT IN THE DESERTED 10TH-17TH CENTURY TOWN BORGUND, NORWAY

**Abstract author(s):** Hansen, Gitte (University Museum of Bergen, University of Bergen)

**Abstract format:** Oral

Driving through small towns in the periphery of Scandinavia, closed down stores and houses for sale are commonplace. The depopulation of marginal districts is disturbing today, but such developments are not new. The Borgund Kaupang, by Aalesund on the west coast of Norway, emerged as a thriving urban community in the late Viking Ages but was deserted some 300-500 years later in the late Middle Ages. The town is a model example that throughout history once-prosperous settlements have also fallen into decay. Borgund was one of Norway’s 16 medieval towns. It was located on the threshold between land and sea along the north -south going sailing route between arctic resource areas and the large town of trade Bergen to the south. Rich marine and inland resources in the hinterland, were probably also of essence for the survival of the town. We know little about Borgund from written sources, but from the mid 1950’s and on archaeological investigations took place here for more than 30 field seasons. Today Borgund boasts the largest assemblage of medieval archaeological sources in Norway, outside the large existing towns. In this talk legacy data from the dawn of medieval archaeology in Norway are addressed to explore destruction and creation as a means to renegotiate and re-define places in face of environmental and political changes. The Borgund kaupang is the case.

10 INVESTIGATING SOCIAL RESILIENCE IN A LONG TERM PERSPECTIVE

**Abstract author(s):** Nordström, Annika (Dept of Archaeology and ancient history, Uppsala Univ)

**Abstract format:** Oral

Ten years ago, major archaeological excavations revealed new evidence concerning the development of the coastal town Nyköping in Sweden. Among other things, the excavations revealed two large, previously unknown boathouses (30x12 m, fitting the Gokstad

ship) dated to c. 650 -1050 CE, and a regulated town plan, dated to the late 11th century. Located in an estuary by the Baltic, high medieval Nyköping was the administrative center of the county of Södermanland, and an important market and meeting place, well situated in the landscape and several seaways. Previous research (building on written sources and available archaeological records) have categorised the town in a group of (mid-Swedish) urban places founded in the mid-13th century. Previous archaeological excavations have also indicated indistinct remains from the 12th century.

In this paper, I will discuss social resilience in a long-term perspective in Nyköping. For the purpose of this study, I define social resilience as the ability of a community to cope with, and adjust to, environmental and sociopolitical change. By using a set of identified breakpoints in the archaeological records, I analyse if and how the event(s) in the breakpoints helped to push the community in a new or different direction – and if and how this coincides with overarching changes in society. The breakpoints range from; the power expressed by the boathouses; the design of the regulated town plan; a cataclysmic landslide or the construction of a town square. How people in the community responded to the changes is analysed in association with the contemporaneous material culture and archeobotanical remains. The ambition is that the result of the analyses can be used to compare development strategies in contemporary places around the Baltic. The study is part of my ongoing PhD-project, and is largely influenced by assemblage thought and social practice theory.

11 THE EMERGING CERAMIC CRAFTSMANSHIP AT ROMAN PATRAS IN AN ERA OF MAJOR SOCIO-CULTURAL CHANGE

**Abstract author(s):** Kougia, Nickoula (Department of Geology, University of Patras; ERAAUB, Departament d’Història i Arqueologia, Facultat de Geografia i Història, Universitat de Barcelona) - Reynolds, Paul (ERAAUB, Departament d’Història i Arqueologia, Facultat de Geografia i Història, Universitat de Barcelona; ICREA, Passeig Luís Companys, Barcelona) - Iliopoulos, Ioannis (Department of Geology, University of Patras; ERAAUB, Departament d’Història i Arqueologia, Facultat de Geografia i Història, Universitat de Barcelona)

**Abstract format:** Oral

Roman Patras, after its establishment as a veteran colony by the emperor Augustus in 16-14 BC, launched a new era as the provincial capital of Achaea that brought wholesale changes in social and economic life to the region. The city was favoured with political and economic privileges that promoted its forthcoming urban development, encouraged by a re-distribution of population to the new urban nucleus. This demographic growth under Augustus brought with it an increasing demand in products that would further trigger a growing consumption in locally produced artefacts. Moreover, the city’s strategic location, along the axis of eastern and western Greece promoted hinterland connectivity and commercial activity, whereas its role as the main port of entry into Roman Greece through the Corinthian Gulf, with Lechaion and Kenchriae, the ports of Corinth, at its eastern end, enhanced its transformation as a key node of maritime trade in the eastern Mediterranean. The needs of the emerging local market, which integrated veterans and other colonial settlers with the local population, supplementary to commercial activity and the ports’ prosperity would have led to the city’s efficiency as a production center. A variety of associated crafts, including the production of ceramic table wares, common wares and amphorae as well as ceramic building materials (brick and tile) further emerged, contributing substantially to the city’s economy and facilitating its role in regional and long distance trading networks. Several years of research have now documented the ceramic workshops within the city and its territory. An overall appraisal of the scale of production demonstrates that pottery craftsmanship was on a par with the major changes in the socio-cultural environment of Patras and Achaea during the Imperial Roman period. The results obtained will enrich the evidence available for the industrialized status of the city of Roman Patras.

12 APPLYING OPTICALLY STIMULATED LUMINESCENCE TO THE LATE BRONZE AGE ANCHORAGE OF MARONI-TSAROUKKAS, CYPRUS

**Abstract author(s):** Kapahnke, Sheri (Texas A&M University)

**Abstract format:** Oral

Coastal sites of trade and connectivity are often entirely or partially submerged in dynamic underwater environments. Similar complicated stratigraphic records in terrestrial contexts are analyzed using tools such as optically stimulated luminescence (OSL), which measures the last time quartz grains in sediment were exposed to the sun. OSL has not previously been applied to underwater sites, but has the potential to clarify an underwater site’s formation and to what extent disturbances have affected artifact positions and associations. In the summer of 2019, OSL methodologies were applied to marine sediment samples from beneath artifacts and from cores taken at the Late Bronze Age anchorage at Maroni-Tsaroukkas, Cyprus (6.0 m depth) to test the capability of the technique to differentiate between disturbed artifacts and those remaining in situ. Combining preliminary screening, and calibrated screening methods provided a relative chronology with the possibility to extract absolute dates in the future. Preliminary screening by means of the portable OSL reader differentiated samples by high (geological, earlier than human occupation), moderate (archaeological), and low (bleached) OSL signals. Comparison between signals from sediment samples beneath artifacts and signals from the same level of sediment within cores made it possible to indicate one anchor which may have moved recently, and one which may have remained in place for considerable time. Additionally, initial stratigraphic conclusions determined factors of sedimentation that could influence interpretation of the site’s artifacts: areas where sand has accumulated without continued disturbance, and differences in accumulation and erosion of silt between the sectors of the site. The results of this initial sampling program are a positive promo-

tion for use of OSL on underwater sites, and encourages the need for further exploration into the methodology in order to improve our means of studying submerged coastal sites in the face of dynamic environmental challenges.

13 COASTAL NETWORKS: THE VIEW FROM GUADALUPE, HONDURAS

**Abstract author(s):** Fecher, Franziska (University of Zurich) - Reindel, Markus (German Archaeological Institute) - Fux, Peter (Museum Rietberg Zurich; University of Zurich) - Cruz Castillo, Oscar (Instituto Hondureño de Antropología e Historia) - Della Casa, Philippe (University of Zurich)

**Abstract format:** Oral

The Atlantic coast of Honduras has been little explored archaeologically. This is despite the fact that the region is located in the overlapping space of three large culture areas: Mesoamerica, Southern Central America, and the Caribbean. Previous theoretical approaches characterize the area as “something in between”, which takes a passive role and is shaped by external influences. However, for the adjacent culture areas, we know that interaction along the coasts intensified especially during the Late Pre-Hispanic period. This contribution presents the results of investigations at the coastal settlement of Guadalupe (AD 900-1525). Due to a strikingly high amount of obsidian and pottery and the presence of jade and metal objects, the settlement occupies a special position in the regional settlement pattern. Using the network approach, existing exchange networks to other sites and regions are reconstructed on the basis of material culture and social practices. The results show that the inhabitants of the pre-Hispanic settlement were involved in different, partly far-reaching networks. The exchange along the coast played an important role for these interactions. We assume that the special position of Guadalupe in the local settlement pattern results from its location on the coast and its function as a broker, presenting a hub between the different networks.

14 OBSIDIAN INTERCONNECTIONS ACROSS THE SEA: THE VIEW FROM THE ISLAND OF CYPRUS

**Abstract author(s):** Moutsiou, Theodora (Archaeological Research Unit, University of Cyprus)

**Abstract format:** Oral

Small quantities of obsidian tools appear in the Aceramic Neolithic (~8900-5300 cal BC) archaeological record of Cyprus in the Eastern Mediterranean. No geological sources of obsidian occur on the island, while an extensive geochemical characterisation programme has shown a number of Anatolian sources represented in the lithic assemblages. Since no land bridge existed between the island of Cyprus and the surrounding Anatolian/Levantine mainland, the existence of obsidian tools on the island necessitates maritime exchange networks. The risks and efforts associated with such practices suggest a conscious choice for obsidian consumption on behalf of these early insular populations and the desire to maintain long-distance interconnections between island and mainland populations. This paper discusses these early obsidian occurrences on the island of Cyprus in the context of maritime interactions and attempts to elucidate the effect of island and coastal movements on the social organisation of early insular communities in the Eastern Mediterranean.

15 SEA FLOOR SURVEY OF ANCIENT MAYA WOODEN BUILDINGS PRESERVED BELOW THE SEA FLOOR

**Abstract author(s):** McKillop, Heather (Louisiana State University) - Sills, Elizabeth (University of Texas at Tyler)

**Abstract format:** Oral

The location of the Paynes Creek Salt Works was selected by the inland Maya need for dietary salt and salted fish. Surplus household production of salt, its transport by canoe up rivers to regional marketplaces, and the presence of non-local pottery and stone tools, underscore the ongoing coastal-inland relations. Salt was made by boiling brine in clay pots over fires inside pole and thatch salt kitchens, whose wooden posts have preserved in a mangrove peat bog below the sea floor. The salt production pottery--briquetage--is ubiquitous at the underwater sites. Surface collection on land has used grids for defining specific areas for surface collection or flagging individual finds. We extended the method for sea floor survey. A program of sea floor survey, including systematic flotation over sites, flagging individual artifacts and wooden posts, and mapping them, results in an opportunity to evaluate the activities associated with salt production. This methodology allowed examination of spatial patterning of activities in different buildings. Ceramic analysis and radiocarbon dating of wooden posts Ek Way Nal, one of the largest sites, indicates use in the Late and Terminal Classic periods and then abandoned (C. E. 600-900). The dates correspond to the height of Classic Maya civilization inland where salt, a basic biological necessity, was in short supply. Analyses of artifacts associated with different buildings indicates fish processing, wood working, ritual and music, were carried out in addition to salt production. The sea floor survey provided valuable information from knowing the spatial locations of finds and will guide planned excavations.

16 WATER SYSTEMS IN RESPONSE TO ENVIRONMENTAL AND SOCIETAL CHANGES. THE CASE OF THE COASTAL SANCTUARY OF HERA AT SAMOS, GREECE

**Abstract author(s):** Androvitsanea, Anna (Universtity of Applied Sciences of Lübeck)

**Abstract format:** Oral

The ancient extra- urban Sanctuary of Hera at Samos is situated in a coastal plain in the Southeast of the Greek island. The hydraulic infrastructure of the archaeological site as well as the performance and vulnerability of its water system since antiquity is currently studied in a joint interdisciplinary research project bringing together civil engineers, hydrologists and archaeologists.

At the Heraion, a sophisticated ancient network of wells and subsurface terracotta pipes has been excavated, which could support many thousands of people sustainably with water. A closer investigation shows that the water supply system of the Heraion was exceptionally well engineered and resilient to even prolonged droughts and moderate floods. The diachronic reconstruction of the functioning of its water system provides an insight into the implementation of different innovations in water engineering. Additionally, it provides a better understanding on how these systems were adapted to climate change and varying societal needs until they finally collapsed, were abandoned or have been modified in order to serve changing needs of water demand.

17 FISHING LINE TECHNOLOGY IN PREHISPANIC SOUTH AMERICA. TIME, SPACE AND CONTEXT

**Abstract author(s):** Flores Fernandez, Carola (Center for Advanced Studies in Arid Zones - CEAZA) - Torres, Jimena (Universidad de Magallanes)

**Abstract format:** Oral

Fishing line is an active and individual technology used by societies inhabiting the shore of lagoons, rivers, and oceans during pre-historic times. Archaeological and ethnographic publications from South America, evidence different types and forms of capture systems and constituent elements such as sliding knots, fishhooks made of shell, bone or cactus spine, and fishing weights made also of shell or stone. These technologies have been used by societies with marine, coastal and terrestrial subsistence strategies, indicating the wide context of this fishing knowledge.

By revising available archaeological literature from Ecuador, Brazil, Peru, Chile and Argentina, we aim to generate a macro regional synthesis about the time, space and context of fishing line technology around the Prehispanic South America. By focusing on archaeological records located on marine littoral environments, we aim to set a comparative framework about the origin and development of this particular technology in used during thousands of years around the Southern part of the American continent.

442 MISUSE OF THE MEDIEVAL IN THE EARLY 21ST CENTURY

**Theme:** 3. The new normality of heritage management and museums in post-Covid times

**Organisers:** Spangen, Marte (UiT - The Arctic University of Norway) - Sindbæk, Søren (Aarhus University)

**Format:** Round table

The historical misuse of archaeology in order to defend and promote ideological standpoints is finding new expressions in the early 21st century, partly due to the development of communication technology and increasingly harsh debate rhetoric in politics and elsewhere. Social media and media in general are demonstrably aiding this development. This affects both the academic community as a whole and individual academics, whether these researchers are online and opposing the outputs or not. Perhaps more worryingly, various productions, commentaries, and debates based on false, skewed, and/or cherry-picked archaeological evidence influence public opinion concerning a series of central cultural-historical, social, and political issues today. This MERC roundtable session will focus on examples of misuse of the medieval in a variety of contexts and referring to a range of archaeological material and research. Furthermore, we wish to discuss the social responsibility and capability of academics to discuss and counter these tendencies in a fruitful way.

443 RE-IMAGINING HOW WE CREATE AND DEVELOP ARCHAEOLOGISTS IN A POST-COVID WORLD

**Theme:** 3. The new normality of heritage management and museums in post-Covid times

**Organisers:** Geary, Kate - Jones, Cara (Chartered Institute for Archaeologists) - Karl, Raimund (University of Vienna)

**Format:** Round table

Round table of the community on the teaching and training of archaeologists.

The training and skill development of archaeologists is traditionally delivered in tried and tested ways, usually starting at university. In 2020, as the profession, like the rest of the world, tumbled into safe-COVID working practice, much of these training opportunities were either disrupted, adapted or cancelled.

2020 has seen our sector change. Like any large world-wide event, the COVID-19 pandemic has shifted our working practice and brought into sharp focus our working methodologies. Never more so than how we develop, train and upskill archaeologists. We ask if this could be a watershed moment with how we deliver this? Is this an opportunity for our profession to reflect and look for innovative solutions or working practices throughout Europe and beyond and consider how they could be adapted for our own training frameworks.

We are keen to hear from a range of organisations and practitioners (at all stages of their careers) who have considered these questions and either aspire to or have created new training mechanisms. We are also keen to hear about the adaptation of the delivery of skills and training in 2020 to minimise disruption or who have identified innovative ways to deliver training opportunities that the sector could potentially continue utilising once this immediate crisis has passed.

Ultimately, we ask if we were starting from scratch, what would be our ideal mechanisms for creating and developing archaeologists?

**Theme:** 6. Material culture studies and societies

**Organisers:** Di Maida, Gianpiero (Neanderthal Museum) - Horn, Christian (Institutionen för Historiska Studier, Göteborgs Universitet) - Schaefer-Di Maida, Stefanie (Institute of Pre- and Protohistoric Archaeology, CAU Kiel; CRC1266)

**Format:** Session with presentation of 6 slides in 6 minutes

The recent increase in projects based on large-scale digitization of archaeological material has made urgent a conversation which reflects critically on issues connected to cataloguing and classification of often ample amount of collected data. On the other side, studies more reliant on traditional methods often neglect digital approaches to test basic clustering in their data. Moreover whereas archaeological classifications, especially typology, have a long history behind them, being at the foundation of the discipline itself, on the other hand digital approaches seem still to be in a tumultuous developing phase. In the archaeological practice a detrimental disconnect between the two approaches, could be problematic, one way or another: by either leading to a positivist enthusiasm towards the new, dismissing well-matured archaeological methodologies, or by setting aside the opportunities digital archaeology can provide.

These issues will be the focus of this session, by discussing projects, approaches, and theories that are situated at the confluence of traditional classification and digital methods, with a specific focus on the practical and directly work-related issues connected with the classificatory work, as for instance reflection on the role of traditional classifications in the development of machine learning for the recognition or analysis of patterns or forms, geometric morphometrics, big data studies of artifacts and other archaeological material.

We are looking forward to receiving presentations from all periods, including pre- and protohistory, classical antiquity, and historical archaeology (e.g. lithics, ceramics, metal, art, burials, architecture, etc.), regardless of their geographical origin. The aim of the session will be to bring together and discuss practical experiences as well theoretical perspectives, linking classification and digital methods in a critical and constructive way, weaving together new and old methods of recording, analyzing, and interpreting the archaeological record into a more mutual-profitable interaction.

ABSTRACTS:

1 TRADIGITAL HUMANITIES. EXPERIENCES IN A CONTEXT OF CHANGE

**Abstract author(s):** Pérez González, Jordi (Universitat de Girona)

**Abstract format:** Oral

At the beginning of the 90's, Judith Moncrieff first coined the term Tradigital art to describe those artistic processes that combined traditional and computational techniques in the creation of an image (physical or digital). In this communication we will highlight, on the one hand, our experience in various projects that have gone from accumulated data to analyzed data and then we will talk about a series of new techniques used with increasing assiduity in the field of Humanities.

Although these computational techniques introduce new methods for the identification of patterns in the data, and promise to accelerate the processes of analysis of the growing mass of data, they diverge from the beginning of the traditional narrative and its methods. In this sense, recent experiences allow us to discuss the benefits and limits of the link between traditional methods and techniques with computational ones when preparing scientific papers. Thus, we believe that without losing sight of the historian's basic essence of continually immersing himself in the reading and analysis of sources, the paradigm shifts of Science can be assumed through the assumption of this new techné.

Consequently, among our main objectives is, first, to analyze the expert figure of the Data science or Chief Data Officer (CDO) within the organization chart of research development, second, to detail the processes of Data Cleaning and Data Quality of the bases of data analyzed and finally summarize the use of new tools such as Carto, Tableau, Flourish, etc. that serve to empower researchers in decision-making in their analysis processes.

2 AMULETS NEED ATTENTION! RETURNING TO THE CLASSIFICATIONS TO BETTER UNDERSTAND THE SMALL FINDS OF TELL EL-GHABA (NORTH SINAI, EGYPT)

**Abstract author(s):** Calomino, Eva (Instituto Multidisciplinario de Historia y Ciencias Humanas - IMHICIHU - Consejo Nacional de Investigaciones Científicas y Técnicas - CONICET; Universidad de Buenos Aires)

**Abstract format:** Oral

Much of the historical-archaeological approaches integrate conceptualisations and classifications for data management, database creation and their submission under qualitative and quantitate analyses. Throughout this classification process, the artefacts are included in categories that generally correspond to previously used names within disciplinary traditions specific to each area of study. In this sense, these categories sometimes have explicit definitions and sometimes do not, hence continuing with the lack of problematisation of the assumptions that said categories entail. In this way, concepts begin to work as "labels" that integrate social and functional assumptions and broader meanings. The categories tend to become diffuse, and, as such, their explanatory power decreases. Something similar has happened with the concept of "small finds" in the research from archaeological sites in Ancient

Near East. A way to remedy this situation is proposed here by presenting a definitive classification proposal for the small finds recovered from Tell El-Ghaba (north Sinai, Egypt, 10th century BC - 7th century BC). The specific and contextual study of the 964 small finds found in the domestic structures of this site seeks to describe and create ways of interpreting the activities carried out by the inhabitants and their beliefs. They were recovered in systematic excavations, and analyzed and recorded under controlled laboratory conditions (by the Argentine Archaeological Mission in Tell el-Ghaba since 1995). The analysis of this sample is carried out from the registration databases -field and laboratory registration sheets, photographs and drawings- and several related publications. This presentation proposes clear and operational tools to approach the study of the relationships between activities and material culture, presenting categories in which the sample can be organized without referring to the functional question as the primary level of object classification and hoping that this proposal can be applied at other archaeological sites in the eastern Mediterranean.

3 THE DISAPALE PROJECT: A 3D DATABASE OF PALAEOLITHIC LITHIC TYPES

**Abstract author(s):** Di Maida, Gianpiero (Neanderthal Museum)

**Abstract format:** Oral

Hosted by the Neanderthal Museum, in the past 3 years, the DISAPALE project (a German acronym that stands for "Digital collection of Palaeolithic lithic types") has been digitally recording more than 1,000 lithic items, building thus quite an impressive 3D dataset of lithic artefacts from different periods and geographical regions.

As it is easy to imagine, the organization of the collected data required the implementation of a cataloguing system of a sort. The obvious choice - that of relying on the existing typological lists - did not come devoid of issues. Typology in fact while it constitutes a core part of the basics for students of prehistoric archaeology in colleges and universities around the world, at the same time it is far from being a fully accomplished field of study: and if this might be said for every field of study, in its case the problems run deeply to its own foundations. Contrary to other apparently similar fields (like cladistics in biology, for instance), the overall impression is that typology is still far from finding its balance.

In this paper, it will be briefly discussed the possibility that the digital recording and cataloguing of artefacts could provide a new renewed impetus to the typological analysis of lithic, with the hope to finally contribute to its more organic development in a fully, scientifically sound branch of study.

4 HYBRIDIZED METHODOLOGY IN CERAMIC SHAPE ANALYSIS: A CASE STUDY OF TYPOLOGY, GEOMETRIC MORPHOMETRICS, AND 3D DATA IN NEOLITHIC JAPAN

**Abstract author(s):** Loftus, James (Kyushu University; Japan Society for the Promotion of Science)

**Abstract format:** Oral

"Japanese archaeology is currently at a methodological turning point" has been a key phrase in the scholarship for more than two decades. With complex statistical analysis becoming the "standard" for modern analysis of shape in western scholarship, the traditional use of notions such as "attributes", and "typo-chronologies" has fallen out of favor. However, for a majority of modern archaeological study in Japan, these traditional aspects are still the favored process. While both have continued to illuminate important gaps in archaeological knowledge, this methodological gap has maintained an ever-growing wedge between Japanese archaeology and the international stage. International impact in the scholarship has continued to fall, with collaborations between domestic and international scholars few and far between.

This author believes that the solution to this precarious situation is not a complete elimination of 'traditional' methods, but instead a hybridization of methods in the analysis of shape. Utilizing a case study in the Jomon-Yayoi Neolithic transitional period, this study shows that a complex integration of typology, chronology, geometric morphometrics and 3D analysis in ceramic analysis can form not only statistically sound, but also holistically qualitative data for use in a variety of uni/multivariate analysis.

5 COMBINATION OF THE OLD AND THE NEW. CHALLENGES IN CONTEMPORARY ROCK ART STUDIES

**Abstract author(s):** Juszczuk, Karolina - Prusaczyk, Daniel (University of Warsaw)

**Abstract format:** Oral

The rock art study is one of the archaeological research areas with a wide range of possibilities in terms of the use of different research methods. Over the past years, with the development of technology, there has been an apparent dispute between the followers of traditional methods used in rock art studies and the supporters of the use of modern techniques. Currently, the prevailing trend is to combine these two approaches.

The aim of our paper is to present the research methodology we developed working on our projects in the Americas. We made an attempt to develop a new, coherent research strategy for rock art. The first project involved investigation at the Toro Muerto site in Peru, which is one of the largest repositories of rock art in the world. The second project was conducted at the Tetzcotzinco site in Mexico, where rock art is less abundant but geographically challenging to document. We will present the methods of documentation and classification of the iconography (based mainly on traditional methods), and its complementation by the use of different digital approaches, which include photogrammetry and scanning. We will also confront the traditional approach of making iconographic typologies with the method of creating digital databases. We will also present the possibilities of embedding the collected data in a GIS, taking into account the problems provided by working with big data (Toro Muerto) and synchronizing different types of data

(Tetzcotzinco). Hence, we will discuss the pros and cons of applying the same research methods at two different sites and present how different classification and interpretation results of rock art studies can be obtained using similar methods on various archaeological material.

Finally, we will present the problem of digitizing and publishing data online, which we also faced while working on the two mentioned projects.

6 A BOAT IS A BOAT IS A...UNLESS IT IS A HORSE - RETHINKING THE ROLE OF TYPOLOGY

**Abstract author(s):** Horn, Christian - Green, Ashley - Wählstrand Skärström, Victor - Lindhé, Cecilia - Peternell, Mark - Ling, Johan (Gothenburg University)

**Abstract format:** Oral

The projects “Rock art in three dimensions” and “Tracing carvers on the rocks” use traditional and 3D documentation, and granite geology to recognize motifs, styles, and utilization of the rock topography with object detection and segmentation. Simply put, these approaches cluster the data according to similarity. While the projects have concrete research questions and purposes, this clustering has also proven to be very useful for exploring the material. To identify their potential meaning any output requires careful interpretation because machine learning struggles with human creativity.

This paper argues that modern big data and machine learning can provide a powerful explorative tool, but it is only effective when typology is reconsidered. Typology was conceived based on 19th century evolutionist ideas as an archaeological tool to establish chronology which has been the major purpose of typology despite criticism and updates. However, chronology is an interpretation made on the similarity that is established by typology. Considering all this, combining typology, machine learning, and geology can create a new framework to interpret human creativity.

7 TACKLING TYPE DETERMINATION AND TYPE ASSIGNMENT WITH THE HELP OF AN APP: THE IDEA OF A DIGITAL ARCHAEOLOGICAL SLIDER PUZZLE

**Abstract author(s):** Roesler, Katja - Auth, Frederic - Domscheit, Wenke (RGK - Romano-Germanic Commission DAI)

**Abstract format:** Oral

In the context of further developing the idai.world we at the RGK are working on the digital display of norm data for archaeological objects. This includes the utilisation of virtuality to develop useful tools for the representation of the archaeological concept of type.

Vessel types usually are presented as unambiguous in archaeological publications. But the many variations of types that oftentimes have to be created, point to the vagueness that is an inherent part in the process of type determination. Furthermore, in archaeological field work ceramic finds are primarily fragmented and thus type assignment is difficult. To approach vagueness and fragmentation, we conceptualised an app under the working title Archaeological FormSlider. Inspired by <https://antlitz.ninja/> and the well-known slider puzzles, we attempt to transfer the effects of these games, that is the precise observation of features, the detection of characteristics not yet perceived, and the consideration of the not or not yet existing, into the handling of archaeological types.

Based on the example of the samian ware types of the *Conspectus formarum terrae sigillatae italic modo confectae*, we made available 1500 Sliders, each displaying parts of profiles. In a first test version of the app the user can browse through the sliders, move them and zoom in and out until they fit to a seemingly existing vessel type. By pressing the resolution-button the reconstructed exteriors of the self-created vessel pop up and the user immediately grasps if one has created an existing vessel, has come near to an existing type or drew up a “chimera”, albeit a possible one. So, by bringing into focus the uncertainty both in the determination and the assignment of a type by means of virtuality we hope to make a meaningful contribution to a long overdue discussion of digital methods and typology.

8 UNSUPERVISED CLASSIFICATION OF SWISS NEOLITHIC POTTERY USING T-SNE AND HDBSCAN

**Abstract author(s):** Hinz, Martin (Institute for Archaeological Sciences, University of Bern; Oeschger Centre for Climate Change Research, University of Bern) - Heitz, Caroline (School of Archaeology, University of Oxford; Institute for Archaeological Sciences, University of Bern; Oeschger Centre for Climate Change Research, University of Bern)

**Abstract format:** Oral

Since 2016, in the SNSF-project ‘Mobilities, entanglements and transformations in Neolithic societies on the Swiss Plateau (3900-3500 BC)’, we have been using a computer-aided classification of vessel shapes to investigate completely preserved Neolithic pottery of Swiss wetland sites and neighbouring regions from the 4th Millennium BC beyond classical typologies and cultural assignments. We follow a holistic approach in which the entire vessel body has been handled as a rotational body. One side of the rasterized, filled and equally scaled profile is extracted, and via a simple transfer of the image information into a matrix, the profile line is converted into 400 measuring points. The profile information, enriched with nominal and metric values, was then classified using a combination of t-sne as ordination and dimension-reducing method and HDBSCAN as cluster algorithm. This approach was complemented by an impressionistic classification by the naked eye.

We have found that the two methods can be used to supplement each other: While computer-aided classification was able to work out more general, cross-stylistic trends, which can be interpreted concerning the functional affordances of the vessels and a consumer perspective, impressionistic classification leads to an identification of different styles, which rather open up a producer

perspective. Combining the results of both strands of analysis can serve to overcome common stereotypes and methodological counter-positions regarding qualitative and quantitative ceramic classification.

9 STATISTICAL EXPLOITATION OF MORPHOMETRIC DATA FOR POTTERY FORMAL CLASSIFICATION: VARIABLES, PROCEDURES AND DIGITAL EXPERIENCES OF SIGNIFICANT CLUSTERING

**Abstract author(s):** Travé Allepuz, Esther (Universitat de Barcelona)

**Abstract format:** Oral

Formal analysis of pottery is a commonplace for most archaeologists regardless of the area or period of study. The classification and typological study of utilitarian earthenwares is quite complex and has often been neglected or considered non-significant in pottery studies devoted to the analytical characterization of vessels. Certainly, a low degree of standardization or the regional character of some productions can jeopardize a definition of vessel typologies with some sense of universality. Despite this, global approach dealing with vessel’s function or technology should also include typological aspects, as they are relevant at the microscale levels and have significance in determining technical choice or distribution.

In the last ten years, we have analysed and quantified vast amount of medieval greyware pottery assemblages. These coarse, plain and highly functional vessels fired under reducing conditions are highly homogeneous throughout the territory. The generation of complete and tidy datasets of morphometric variables and their exploitation via Principal Component Analysis (PCA) and Hierarchical Cluster Agglomeration (HCA) among other statistical approaches and graphical representations has lead us to the identification of regional typologies with chronological meaning. Clusters resulting from a combined study including up to four diametres, wall thickness, absolute, preserved or reconstructed height, and vector profile measurement allowed us to determining degree of breakage and to consider this variable it typological definition [1].

With our six-slide-short contribution, we aim at sharing our procedure and experience, and to discuss from a theoretical perspective its relevance for pottery studies in general and medieval common wares in particular.

[1] Travé E, Domingo G, Vicens J, Mauri A (2019): “Morfometría de cerámicas grises catalanas: Algunas consideraciones sobre la definición de tipos en cerámica común de época medieval y postmedieval”, *Zephyrus*, 84: 161-182.

10 POTTERY, 3D IMAGING AND ARTIFICIAL INTELLIGENCE: DEVELOPMENT OF A NEW METHOD FOR THE AUTOMATIC RECOGNITION AND CLASSIFICATION OF DECORATION TECHNIQUES

**Abstract author(s):** Cassard, Laura (Université Côte d’Azur, CNRS, CEPAM UMR 7264) - Kaur, Jasmine - Yao, Jean-Élysée (Université Côte d’Azur) - Coli, Vanna Lisa - Binder, Didier (Université Côte d’Azur, CNRS, CEPAM UMR 7264)

**Abstract format:** Oral

Traditionally, the identification of the tools and gestures used to print ceramics is done by qualitative analogy between archaeological and experimental prints. To this end, in addition to direct observation of the artefacts, technical drawings, photographic records or casts are generally used to document the observations. Although it gives satisfactory results for the determination of general typologies, this method is time-consuming, often limited to selected sets and is accompanied by a certain degree of subjectivity. Recently, the development of a new method for analysing pottery decoration using 3D imaging has considerably improved the processes for identifying and classifying printing tools and gestures. This method consists in high quality scans, performed with a structured light scanner, which allow for the rapid acquisition of 3D data. Pottery series are thus fully taken into account. Thanks to the accuracy of the 3D models, analogies of shapes, as well as the dimensions of decorative prints (length, width, depth), can be directly implemented in the models. Typologies are provided with more details and the identification criteria are more relevant. However, this approach still requires the operator’s judgement and does not yet exploit all the available 3D information. In addition, the use of 3D leads to an increase on the quantity of data and on the difficulties of processing. Our aim is to focus on Artificial Intelligence analysis methods in order to manage previously acquired digital data. From a dataset of experimental 3D models, we seek to characterise the whole print (shape and dimensions). We then explore the possibilities of automatic recognition and classification of the printing tools and gestures using Machine Learning methods. The creation of such algorithms aims to achieve an objective and comprehensive characterisation of the prints and thus increase the potential for data interpretation, while reducing the examination time.

11 A NOVEL APPROACH FOR NEURAL NETWORK-BASED CLASSIFICATION WITH EXPERIMENTAL BONE SURFACE MODIFICATIONS

**Abstract author(s):** Orellana Figueroa, Jordy (Department of Early Prehistory and Quaternary Ecology, University of Tübingen) - Sahle, Yonatan (Department of Archaeology, University of Cape Town)

**Abstract format:** Oral

The identification of archaeological bone surface modifications (BSMs) as anthropogenic in origin has been an important goal for zooarchaeology, with wide-ranging implications for our understanding of human evolution. Traditionally, the identification of BSM effectors (e.g. lithics or teeth) involves the examination of the morphological characteristics of experimental bone marks (where the effector is known), and the application of the insights gained to the identification of archaeological BSMs. However, there still

exists much disagreement amongst researchers regarding the different methods used, even whether equifinality makes a solid identification possible in all cases (e.g. [1]).

The debate is unsurprising, as a method capable of reliably identifying the effector of BSMs, when applied to archaeological data, could—for instance—confirm the need to push back the date of the earliest evidence for stone tool use by several hundred thousand years (e.g. [2]).

Newer approaches have focused on the application of more computationally-based methods to BSM identification—including the use of neural networks and other machine learning algorithms—with some success.[3]

We present here the methods and preliminary results of a novel approach for the application of neural network-based classification on a dataset of experimental BSMs. The BSMs were classified into two categories, based on the identified effector: ‘lithic’ or ‘(crocodile) tooth’. Through the use of data augmentation and regularisation techniques, as well as a simple neural network architecture, we obtained a mean classification accuracy of 92.60% across 30 runs. In this presentation, we discuss the advantages, disadvantages, and limitations of our methodology, and place it in context with the most recent applications of machine learning to BSM identification.

## QUANTIFYING PATTERNS IN MORTUARY PRACTICES: AN APPLICATION OF FACTOR ANALYSIS TO DATA FROM THE TAOSI SITE, CHINA

**Abstract author(s):** Bai, Yang (Kyushu University)

**Abstract format:** Oral

In modern Chinese research, too much reliance on traditional qualitative typological analysis renders quantitative elements of mortuary practice data ignored. In this research, one of the famous cemeteries in China, the Taosi cemetery (2300-1900BC), has been chosen as the case to discuss the advantages and shortcomings of typology and digital methods. Extant researches adopted non-quantifiable typological methods to classify the Taosi burials, that was divided into six vertical categories, representing a pyramidal social hierarchy. However, this approach solely relied on the presence and absence of respective grave good items and the outcome was highly subjective and difficult to verify. The study applies Factors Analysis to investigate all the variables that can be extracted from the data, including both grave goods and dimensions of mortuary facilities, and their correlations in order to overcome such shortcomings. The statistical factor scores have quantified the differences in the combination of burial objects in different tombs and allowed clarification of the process of choosing burial objects and their implication for different social meanings. The result shows two axial divisions in the Taosi Cemetery: vertical stratification based on hierarchy and horizontal differentiation based on social categories/identities such as soldiers and elites' servants. Compared with the simple description of typology, such a quantitative method can reveal the characteristics of each category much more clearly, clarify the classification criteria, and extract much more detailed information about the mortuary practice and society.

## TOOLS MODIFICATION DEGREE DEPENDING ON THE SPATIAL LOCATION (TOLBOR-21, NORTHERN MONGOLIA)

**Abstract author(s):** Marchenko, Daria - Rybin, Evgeny - Khatsenovich, Arina (Institute of Archaeology and Ethnography SB RAS, Novosibirsk)

**Abstract format:** Oral

The Tolbor-21 site in the Selenga River Basin is an important evidence of the northern Mongolia occupation by Initial Upper Paleolithic (IUP) population. It is represented by the material of archaeological horizon 4 (AH4). Two groups of combustion features (CF1 and CF2) were found in the area of the highest concentration of the findings in the Pit 2. Hearths are usually considered to be the centers of activities, determining spatial patterns of findings. The aim of the study was to examine the variability of tool-making in this area and consider the connection of combustion features with spatial patterns of the tools with different kinds of modifications.

We clustered the tools from the Pit 2 (N = 100) taking into account the secondary treatment parameters: the degree of tool edges modification and retouched part of the tool perimeter (from 1/4 to 4/4). Four groups of modification (slightly, medium, intensive, significant) were distinguished as a result of independent use of k-means and agglomerative hierarchical clustering. Distribution of these modification groups from the Pit 2 has been studied in connection with combustion features locations. We used unconstrained clustering that creates clusters according to percentage of findings. Results indicate reliable three-clusters division: two clusters are related to combustion features, and one cluster cover the rest area.

Thus, almost half of the tools have a medium modification, 20% - intensively modified, and 4% - significantly modified. Combustion features influence on spatial patterns of modification groups: significantly modified tools are related to CF1, medium modified tools predominate in CF2. Area with no combustion features has the greatest percent of slightly modified tools. This distribution suggests that CF1 was associated with an activity that required the most modified tools.

This study was supported by the Russian Science Foundation grant No. 19-18-00198.

## COMBINING TRADITIONAL AND DIGITAL APPROACHES: APPLICATION OF STATE SEQUENCE ANALYSIS TO THE STUDY OF LONG-TERM EVOLUTION OF SETTLEMENTS

**Abstract author(s):** Drillat, Quentin (Ghent University)

**Abstract format:** Oral

Settlement patterns and networks are traditionally studied as snapshots of a landscape organization. Their structure is described based on the hierarchical levels of each settlement at a given period. These hierarchical levels are attributed considering a number of variables including characteristic artifacts, settlement size and functions, that are studied in a pure archaeological or statistical approach. Some projects already introduced the time-component including chronological variables such as total duration of occupation and date of first implantation in the considered variables when clustering settlements. However, the resulting typologies do not consider chronological variation. This paper explores the way traditional archaeological classifications of settlements can be reemployed in a quantitative approach to study the evolutionary trajectories of settlements in a long-term perspective. Evolutionary trajectories are built compiling hierarchical levels determined for each occupation period of settlements (with either a traditional or a statistical approach), and State Sequence Analysis based on Optimal Matching is proposed as a tool to measure their variability. A cluster analysis finally groups trajectories and detects trends in the long-term development of settlements. Applied to the case-study of the Anapodaris river catchment (Crete, Greece), this approach enables to study the trajectories of 6 cities known from the 9th century BC, among which 2 or 3 become independent city-states after the 6th century. Hence, State Sequence Analysis offers a new perspective in the study of the evolution of landscape organization and allows to improve the modelling of city-states territories.

## INTERDISCIPLINARY RESEARCH OF EARLY BRONZE AGE AXE HOARD (KUKLENY, CZ)

**Abstract author(s):** Schimerová, Eva (University of Hradec Králové) - Havlíková, Markéta - Nosek, Vojtěch (Masaryk university)

**Abstract format:** Poster

The hoard of bronze axes found in Kukleny contained 56 axes, which makes it the largest Early Bronze Age hoard of axes from Czech Republic. The Hradec Králové district has always been considered as a periphery within the period. This hoard proves that this opinion is wrong and it also proves important position of the region on the intersection of routes between Poland, central Bohemia and Moravia. Our contribution introduces a set of documentation methods (Image Based Modelling – SfM, RTI, Laser Aided Profiler, Metal wear analysis), that are aimed on non-destructive and interdisciplinary research of Bronze Age artefacts. On this example we would like to present a documentation procedure that enables a complex study of artefact. It is focused on recognition of traces of manufacturing and use-wear traces (in combination with metallographic analysis). Result is a set of data that enables further analysis and preservation of information value of each artefact. Our goal is to create a platform that would enable to see correlations between other similar finds throughout Central Europe. The gained data is important not only when discussing hoards as phenomenon but also for the use-wear analysis itself and for typology of axes. The existing typologies are usually repetitive, locally based and in many cases very vague. We presume these categories represent very subjective opinion of each author. We believe that by precise documentation and comparison we can obtain important information that exceeds conventional typologies. For example by precise comparison of shape we can find out whether any of them were made in the same mold or based on the same model. We can also gain better understanding if manufacture technology. By metal wear analysis we can determine whether the axes were used as tools or weapons or if they represented a symbol of status in society.

B.

## AN INTEGRATED APPROACH TO 3D WEB DATA SERVER CLASSIFICATION: CORPUS VASORUM HISPANORUM

**Abstract author(s):** Bustamante Álvarez, Macarena (Universidad de Granada) - Angás, Jorge (Universidad de Salamanca)

**Abstract format:** Poster

We present the design of database that wants collect all the stamps on one of the most important ceramic categories in roman Hispania, the hispanic samian ware.

Our proposal allows us to join a relevant set associated with the information of each sigilla through a relational database. The characteristics of the developed web platform can be summarized as:

- analysis and development of a relational database with different types of information.
- generation of graphs from data sets.
- design of an interface for the front end and for the back end that allows complex searches.
- geographic representation system.
- 3D digitization of those parts that are uniquely relevant for later viewing and taking measurements using the WebGL standard specification.

So far we have collected more than 1000 stamps located in what was the former province of Lusitania.

This project becomes a pilot experience that allows obtaining typochronological data of some abundant pieces in the archaeological interventions of the ancient territory of Hispania.

EUROPEAN CRYPT BURIALS II - A HERITAGE (STILL) AT RISK BETWEEN SCIENCE AND PUBLIC DISPLAY

**Theme:** 6. Material culture studies and societies

**Organisers:** Alterauge, Amelie (Institute of Archaeological Sciences, University of Bern; Institute of Pre- and Protohistory and Near Eastern Archaeology, University of Heidelberg) - Majorek, Magdalena (Institute of Archaeology, University of Lodz) - Grömer, Karina (Department of Prehistory, Natural History Museum Vienna) - Väre, Tiina - Lipkin, Sanna (Department of Archaeology, University of Oulu)

**Format:** Discussion session

Church vaults were used as burial places for the European nobility, bourgeoisie and clergy between the 16th and 19th century AD. Due to the environmental conditions, the complete inventory of a crypt is often preserved, including coffins, fabrics, clothes, personal goods, botanical and human remains. These crypts give us important insights into the funeral customs, beliefs and traditions of the early modern period and allow us to investigate sepultures of the social elite in great detail. The vaults are also places of memoria, social representation, familial affiliation and resurrection, which becomes evident through the elaborately decorated and inscribed coffins. Though, crypts are often at risk due to changes to the built environment, cutting off the required ventilation to preserve organic materials. In this regard, conservational interventions are important to the preservation and potential public display of crypt burials.

Researchers from various European countries gathered during Session #375 at the EAA 2019 in Bern and presented individual case studies, resulting in a volume of the “Acta Universitatis Lodziensis. Folia Archaeologica” (2020).

The goal of the session's revival is to focus on the following aspects of crypt burial and of crypt archaeology:

- Cultural history: development and origin of crypt burial, transformation of funeral rituals;
- Archaeological evidence: crypt and coffin types, grave goods, symbols/objects of faith, inscriptions, clothing;
- Methodology: documentation techniques, methods for identification, infestation risks;
- Ethics: professionalism in crypt archaeology, handling of human remains, accessibility and current use of crypts.

Our aim is to go beyond local case studies in order to achieve a better understanding of regional and large-scale trends in early modern burial traditions.

ABSTRACTS:

1

OLD CRYPTS IN NEW SPLENDOUR

**Abstract author(s):** Ströbl, Regina - Ströbl, Andreas (Forschungsstelle Gruft)

**Abstract format:** Oral

Throughout Germany numerous tombs have been investigated and restored in the past two decades.

It has been shown that interdisciplinary co-operation makes sense from the start, both scientific investigation and restoration, which leads to remarkable results.

Interplay between the disciplines of archaeology, art history, folklore, anthropology, history, botany and theology on one hand and the restoration disciplines of wood, metal, textiles and stone on the other has sometimes led to impressive results.

After severe damage by damp and looting, most of the burial tombs from the early modern period are still in a deplorable condition. But even severely devastated burial vaults with mostly rotten coffins can be restored to a dignified condition in order to make the “Gesamtkunstwerk” of the tomb experienceable for future generations and to evaluate the knowledge gained.

Co-operation is planned with colleagues from Austria, Denmark, the Netherlands and Estonia who are interested in the documentation and restoration methods developed in the past 20 years.

CRYPT BURIALS IN GERMANY– PAST RESEARCH AND CURRENT TRENDS

**Abstract author(s):** Alterauge, Amelie (University of Bern)

**Abstract format:** Oral

The aim of this paper on crypt burials is to provide an overview on past research projects and current trends in German crypt archaeology. Over the last three decades, several crypts throughout Germany have been documented, usually in the context of church renovations. A growing interest in historical archaeology has led to scientific investigations and conservational interventions in these crypts, even though the state of publication has not yet met the standards set for older periods.

Since the beginning of crypt archaeology in the 1980s, there has always been a strong interdisciplinary collaboration between archaeology, physical anthropology and historical sciences, including genealogy and costume history. In recent times, methods from forensic sciences have been applied, too, thus creating a deeper knowledge on individual inhumations.

Well-researched geographical areas with several documented crypts are Northern and Eastern Germany, while evidence mainly lacks for Western and Southern Germany. The reasons for this unequal distribution are a mix of historical, religious and political fac-

tors, which nonetheless call for a comparison of burial practices throughout the country. In particular, differences between Catholic and Protestant burials have been recognized regarding the crypt's location, coffin decorations as well as the grave goods.

Besides that, the growing body of evidence reveals temporal changes in burial practices, reflecting a changing attitude towards death. The individual, social and religious purposes of crypt burials can only be understood when tracing their beginnings, development and modern adaptation through time. Therefore, a global view will complement our knowledge of regional factors.

3

ON THE WAY TO A EUROPEAN COFFIN TYPOLOGY

**Abstract author(s):** Ströbl, Regina - Ströbl, Andreas (Forschungsstelle Gruft)

**Abstract format:** Oral

Six years ago, a coffin typology and terminology of coffin components was presented with the aim of uniformly recording and naming the different coffin forms from the early Middle Ages to modern times. During the examination of numerous European tombs, many different coffin types were documented and new ones are being discovered all the time.

Discussions with colleagues from Britain, Sweden, Austria, Italy and Germany have shown that an international exchange is necessary in order to standardise the scientific recording. This also applies to gravestones, tombs and epitaphs.

Such an exchange is also valuable in order to shed light on hitherto unknown relationships between European countries and cultural transfer of sepulchral culture. For example in the 17th and 18th centuries new coffin types brought to Germany from Italy and France containing Germans who had died abroad.

The extensive coffin inventory in the Catacombe dei Cappuccini in Palermo has never been studied scientifically. A project on this matter is being planned.

4

TYPES AND IMPORTANCE OF PLANTS AND FLORAL ORNAMENTAL MOTIFS IN BURIALS FROM THE CRYPTS (17TH - 19TH CENTURIES IN POLAND)

**Abstract author(s):** Majorek, Magdalena (University of Lodz; Institute of Archaeology)

**Abstract format:** Oral

Plants had a special place in the funeral rites. Their presence with the deceased was not accidental and, apart from the decorative value, was dictated by tradition, beliefs, customs or even superstitions. Thus, the set of plants or floral ornamental motifs, e.g. on coffins, had its meaning and symbolism. Archaeological research is a source of knowledge on the basis of which we can learn about the rules governing the funeral customs.

As part of my speech, I would like to present the following issues:

- plant motifs on coffins (painted, metalwork, decorative entombs),
- plant motifs on clothing and upholstery fabrics found at burials,
- plant fillings for mattresses and pillows (diasporas: seeds and fruit, flowers, leaves and plant shoots),
- bouquets and plant wreaths placed in / on coffins and during funeral ceremonies (arrangement, shape, fresh flowers, artificial flowers),
- spiritual and religious meanings built on the basis of plant elements of nature; the importance of plants.

I will rely on my own field experience gained during archaeological research of post-medieval and modern crypts and cemeteries in Poland as well as on the subject literature (archaeological, historical, ethnographic and art history).

5

MUMMIFICATION, PRESERVATION, AND DECAY IN FINNISH CRYPT BURIALS

**Abstract author(s):** Väre, Tiina - Lipkin, Sanna - Kallio-Seppä, Titta - Junno, Juho-Antti - Tranberg, Annemari (Archeology, University of Oulu)

**Abstract format:** Oral

The paper concentrates on the conditions in Finnish crypts and the preconditions of mummification of their remains. These conclusions are based on the inventories below four northern Finnish churches and one privately owned chapel at Kourla, in southern Finland.

During the 18th and early 19th centuries, particularly the elite burials were made beneath the parish churches. Later the practice became popular also among lower classes. After the ban of the church burial tradition in the early 19th century the church renovations made during the 19th and 20th centuries have destroyed much of this heritage in many churches. In other, however, the deceased and their funerary attires and decorations have preserved in a rather unique way.

As a final resting place, the church basements and the privately-owned chapel have some noticeable differences. In Finland mummification is often a result of freezing winters. The suitable and stable humidity below the church floors enables good preservation of both mummified remains, coffins, and fabrics. While the remains in churches were likely naturally mummified, our research indicates the mummified remains in Kourla chapel were likely embalmed. It was customary to embalm members of the elite, and indeed the church records indicate of several months long wake periods. The Church did not allow the deceased to be buried in unconsecrated land. The Kourla chapel owned by a noble family was built away from the churchyard with a separate granted right from the Crown.

The presentation also considers the later human disturbance and its influence on the decay. In the Kourla chapel the location on a private land has enabled random invades by individuals out of pure curiosity. These actions have led to different kind of changes in the remains and affected their preservation.

MULTIDISCIPLINARY APPROACHES TO ENVIRONMENTAL AND HUMAN FINGERPRINTS OF THE ROMAN PERIOD

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Silva-Sánchez, Noemí (Instituto de Ciencias del Patrimonio - Incipit. CSIC; EcoPast Research Group - GI-1553. Universidade de Santiago de Compostela) - López-Costas, Olalla (EcoPast Research Group - GI-1553, Area of Archaeology, Dpto of History. Universidade de Santiago de Compostela) - Jones, Samantha (School of Geosciences. University of Aberdeen) - López Barja de Quiroga, Pedro (Síncrisis Research Group - GI-1919, Univ. of Santiago de Compostela) - Mighall, Tim (School of Geosciences. University of Aberdeen)

**Format:** Regular session

The Roman Republic and Empire were a time of intense social and environmental transformations in vast areas of Europe, the Middle East, and North Africa. The huge impact on landscape and people's lifestyle is therefore key to understanding both the subsequent environmental and human histories of these regions. The aim of this session is to build a global perspective based on local narratives by integrating historical, archaeological and environmental research. In this session, we invite researchers to contribute to explore the environmental and human fingerprints during the period in which Rome was a Mediterranean power (200 BC -AD 500) in Roman ruled areas and their vicinities, as well as discuss together its legacy.

This Regular session is designed to transcend (mono)disciplinary studies to reach an integrative vision with examples from Roman-ruled areas. We welcome multidisciplinary approaches that encourage the comparison between historical sources, classical archaeology and environmental archaeology, including bioarchaeology and geoarchaeology approaches to build an integrative story of the human-environmental interactions during Roman times.

The type of questions this session will address are: do historical texts, (bio)archaeological data and environmental findings share a common narrative? How can a fruitful dialogue between different disciplines be established? The contributions will consider the following topics or others that fall within the scope of the session:

- Migrations (human and animal)
- Health state along time and pestilences
- Agriculture, livestock strategies and their impacts (e.g., new crops, staples, palaeodiet, pastoralism, erosion, deforestation)
- Mining, metallurgy and their impacts (e.g., deforestation, pollution)
- Impacts of social transformations on landscape and economy
- Landscape, environmental and climate change
- Regional comparisons: Atlantic vs. Mediterranean; Western vs. Eastern Roman Empire; North vs. South

ABSTRACTS:

1

PRELIMINARY RESULTS ON THE ARCHAEOBOTANICAL ANALYSIS OF PLANT MACROREMAINS FROM THE ROMAN AGE PERIOD

**Abstract author(s):** Apiar, Jana (Institute of Archaeology of the CAS, Brno, v.v.i.)

**Abstract format:** Oral

The presentation is showing preliminary results of the analysis of carbonized plant macroremains. The researched issue took into account several archeological sites of the Roman Age period. They were situated mainly in Slovakia, Moravia, and the Bohemia region. According to the main results, differences in the plant assortment were present. Cereal proportions on individual sites were variable. Therefore, the identification of wider regional groups based on the occurrence of cereals has been problematic. Between barbarian-Germanic sites and sites situated closest to the limes, a slight difference in crop product finds was discovered.

Only minor differences in crop treatment and storage were present among the sites in the early stages of the Roman Age period. The sites were similar in crop product type composition. Nevertheless, the contrast was a higher density of plant macroremains obtained from the sites situated closest to the limes. The differences were gradually deepening in the later stages of the Roman Age. Cereal products as (un)thrashed ears, and their by-product residues prevailed on some sites. On barbarian-Germanic sites, the composition of cereal product types was more balanced, with a predominance of clean grain. Early and later phases of crop processing were present at all sites.

The results are contributing to the debate of usage of the archaeobotanical methods at the excavated sites. Each analyzed site was sampled differently, with a diverse number of samples collected and unequal volume per sample taken. Formal archaeological information was of unequal quality, too. This heterogeneity itself caused that not all samples could be analyzed equally. It has also caused the results to be marked by a degree of uncertainty. Consequently, patterns of the analyzed data can also represent a sampling or methodology bias itself.

2

ECONOMIC,-SOCIAL-AND-ENVIRONMENTAL-IMPACTS-CAUSED-BY-THE-RISE-AND-SUBSEQUENT-ABANDONMENT-OF-ELITE-NODES-OF-POWER-AFTER-ROMAN-WITHDRAWAL-FROM-BRITAIN: A-CASE-STUDY-FROM-A-PICTISH-ELITE-CENTRE-IN-NORTHEASTERN-SCOTLAND-BETWEEN-THE 4TH-6TH CENTURIES-AD

**Abstract author(s):** Jones, Samantha - Evans, Nick (University of Aberdeen) - Martínez Cortizas, Antonio (Universidade de Compostela) - Mighall, Tim - Noble, Gordon (University of Aberdeen)

**Abstract format:** Oral

The first millennium AD in northern Europe is still a dark age in terms of our understanding of Late Roman and post-Roman societies, with few written sources and an archaeological record that has been traditionally lacking in evidence. This is particularly true of the Picts in Scotland. First mentioned in late Roman-period sources, the Picts inhabited north-eastern Scotland until the late 1st millennium AD. The weakening of the Roman Empire in southern Britain and final withdrawal between the late 4th and early 5th centuries AD had a profound impact on the whole of Britain leaving the Brittonic tribes more susceptible to international and national raids (more so in the south – however both north and south were impacted). It is during this period that the archaeological record appears to show a rise in the construction or reoccupation of fortified settlements in northern Britain. Rhynie in Aberdeenshire is a good example of this with two fortified enclosures that date to the late 4th century AD (the Craw Stane Complex and Cairn more). In this paper we focus on the Craw Stane complex, an elite centre which was occupied from the 4th-6th century AD. During five seasons of excavation, more than 1000 artefacts were recovered including symbol stones, Mediterranean pottery, glass, metalwork and evidence for non-ferrous metalwork production. Despite the wealth of archaeological data obtained from the Craw Stane complex we still know very little about the day-to-day life of the early medieval people in this valley and why the Craw Stane complex was abandoned in the 6th century AD. By combining paleoenvironmental analysis (pollen, non-pollen-palynomorphs, and X-ray diffraction) with available historical and archaeological archives we provide new insights into the economic, social and environmental impacts caused by the rise and subsequent abandonment of this elite node of power.

3

DIVERSIFYING NARRATIVES. AGRICULTURAL CHANGE AND RESILIENCE AMONG IRON AGE SOCIETIES IN THEIR INTEGRATION INTO THE ROMAN STATE

**Abstract author(s):** Teira-Brión, Andrés (Universidade de Vigo)

**Abstract format:** Oral

The assimilation of Iron Age communities of the Iberian Northwest into the Roman state is a controversial and still unresolved subject of debate. In order to observe the impact of Roman acculturation, agriculture and the exploitation of wild plant resources offer us the possibility to understand how their life-styles and the exploitation of the territory changed or resisted. For this purpose, an archaeobotanical approach was taken, integrating all published seed analyses through multivariate statistics. The results obtained provide crucial information for understanding the social and economic settings.

The formation of hillforts, as the predominant settlement model, led to a series of social and economic consequences, which reflected on the interaction between the communities of the Northwest of the Iberian Peninsula and the environment natural resources. The transformation of the agrarian systems during the 1st millennium BC meant a change of trend towards an economic system based on the accumulation of surpluses, mainly cereals, within the existing crop diversification. The irruption of Rome into this scenario meant, on the one hand, a reorganisation based on a new administrative system, a change in the socio-economic model and, on the other, the immersion of the Northwest in the trading of products and ideas between the Atlantic and the Mediterranean. Through these routes, new crops, agricultural practices and different rituals in the consumption of plants arrived. However, these changes were uneven and with different intensities between the new Roman settlements and the model inherited from the Iron Age.

4

LANDSCAPE-SCALE INDIRECT HYDROLOGICAL TRANSFORMATIONS DURING ROMAN TIMES

**Abstract author(s):** Silva-Sánchez, Noemí (Instituto de Ciencias del Patrimonio, Incipit-CSIC) - López-Merino, Lourdes (Universidad Complutense de Madrid, Facultad de Farmacia, Unidad de Botánica, ENVIROVEG, grupo UCM 910164) - Martínez Cortizas, Antonio (Universidade de Santiago de Compostela, Facultade de Bioloxía, EcoPast - GI-1553)

**Abstract format:** Oral

It is well known that during the Roman expansion across Europe hydraulic engineering experienced a golden period. Examples of hydraulic architecture such as aqueducts for civic, domestic, farming and industrial purposes still remain in many cities (Segovia, Tarragona, Metz, Belgrado, Tivoli, etc.). Hydraulic mining systems are also very well known, such as ‘ruina montium’, which have left large-scale evidence of transformations of the landscape (e.g., Las Médulas). The work presented here focuses on less obvious hydric modifications, which were the indirect result of other anthropogenic activities. The combination of geochemical and palynological approaches in peat archives has provided evidence that, in many different places across Europe, environmental transformations associated with Roman mining, as well with other activities such as forest clearance, resulted in significant, landscape-scale, hydrological changes. These changes led to an increase in run-off and soil erosion in some areas, but also to the formation of peatlands due to a rise in the water table. At Cruz do Bocelo Mire (NW Iberia; Silva Sánchez et al., 2014), for example, the transition from the Iron Age to the Roman Period was a tipping point in the buffer capacity of the catchment in terms of water retention. As a result of a large deforestation event, which occurred between AD 210 and 240, and contrary to what had happened before, the mire hydrology started to respond more abruptly to changes occurring in its catchment. Similarly, in their study of La Molina mire, López-Merino

et al. (2011) concluded that between the AD 20 and 140 it would have been used as a ‘piscinae’, marking a no-return point in its hydrological conditions, which led to a change from a minerotropic to an ombrotropic status (responsible for its present declaration as protected habitat in Natura 2000 network).

5 **DISCREPANCIES IN THE RECONSTRUCTION OF ROMAN RIVER LANDSCAPES : FISH, BOATS AND WHAT WE CAN DO WITH THE LEGAL TEXTS**

**Abstract author(s):** Ronin, Marguerite (CNRS)  
**Abstract format:** Oral  
How do we integrate Roman legal texts (mainly contained in the Digest of Justinian) with more traditionally considered pieces of documentation (archaeology, inscriptions, literary texts...) and why does it matter anyway? While legal texts present major drawbacks for historians (i.e. debatable chronological and geographical context, ill-defined scope of application), I argue that they can improve our understanding of ancient landscapes because, dealing as they do with human activities, they can help us reconstruct economic and social uses of an environment not necessarily well documented from an archaeological/historical perspective. But first, we must address their defining features and establish a methodology for their integration.

Rivers and riverside activities are a good starting point to explore ways of integrating different pieces because they constitute a crossroad for competitive uses of water as a resource (irrigation, supplying of workshops, fountains and piscinae...) and of rivers as an environment (transport, water wheels, ports and embankment, dams, and of course fishing). As waterway transport was crucial to supplying urban centres and to exports, it is not surprising to find many legal texts referring to activities hampering the navigation and providing judicial tools to limit these. Amongst the many activities that can change the course of the river by making its bed narrower or its current faster, we may assume that legal texts refer to permanent or semi-permanent fishing installations. It is, however, hard to find them in archaeology and the literary sources hardly mention fishing activities in rivers. My aim is therefore to explore these discrepancies and to try to provide some methodological avenues for the cross-reading of different types of documentation.

6 **ENVIRONMENTAL CHANGE IN MAURETANIA TINGITANA**

**Abstract author(s):** López-Costas, Olalla (EcoPast - GI-1553, Archaeology Fac. de Xeografía e Historia, Universidade de Santiago de Compostela; Archaeological Research Laboratory, Stockholm University; Laboratorio de Antropología Física, Universidad de Granada) - Martínez Cortizas, Antonio (EcoPast - GI-1553, Facultade de Bioloxía, Universidade de Santiago de Compostela) - Iriarte, Eneko (Laboratorio de Evolución Humana, Universidad de Burgos) - García-López, Zaira (EcoPast - GI-1553, Facultade de Bioloxía, Universidade de Santiago de Compostela) - Peña Chorcarró, Leonor (Instituto de Historia, Centro de Ciencias Humanas y Sociales, CSIC) - López Merino, Lourdes (ENVIROVEG, grupo UCM 910164.Unidad de Botánica, Facultad de Farmacia, Universidad Complutense de Madrid)  
**Abstract format:** Oral

The Rif (Northern Morocco) was settlement of numerous cultures due to its strategic position. Although Mauretania Tingitana was formally incorporated within Roman frontiers by AD 40s, the Roman presence in highlands such as Middle Atlas was apparently only nominal. In contrast, lowland settlements close to the sea (e.g., Tingis, Lixus) or inland (e.g., Volubilis) were highly populated and the drivers of Roman culture spread. On one hand, the Rif was close enough to them, and surrounded by Roman roads, so intense occupation may be expected. On the other hand, their mountainous nature could have prevented an intense romanization. Considering the history of human occupation and the known scale of Roman transformations of western Mediterranean landscapes, we wonder if the Rif Mountains were also significantly impacted in Roman times.

Under the framework of the AGRWESTMED ERC grant, we collected a sediment core at Bab el Karn, a wetland located on the northern slopes of Jbel Khesana (Western Rif). We performed colour, IR-spectroscopy and geochemical analyses, in order to understand the wetland environmental history in the last four millennia. We found four main environmental signals: fine mineral matter fluxes from the catchment, variations in organic matter accumulation, changes in diatoms’ production and in the degree of oxygenation of the lake. By the onset of Roman times the wetland shifted abruptly from permanent to seasonal. This evolution is framed within the western Mediterranean aridity trend and the regional onset of deforestation in the Rif area. Surprisingly, the increase in diatoms during the Roman period can be interpreted as indicating a lower impact on the lake water quality. In sum, Roman times represented a tipping point in the wetland dynamics. This stresses the importance of including environmental information in the debate about differences in the occupation of lowlands and mountainous areas of Mauritania Tingitana.

7 **BEYOND NEMAUSUS: THE EXTENSIVE ENVIRONMENTAL PRINT OF THE ROMAN CITY THROUGH THE INVESTIGATION OF A PALAEO-CHANNEL**

**Abstract author(s):** Save, Sabrina (Amélie SARL) - Flaux, Clément - Scrinzi, Maxime (Mosaïques Archéologie)  
**Abstract format:** Oral  
Where and when do cities start and end? The Roman city of Nemausus (Nîmes, Southern France), capital city of the Volques Arécomiques established around the source of the river Le Vistre de la Fontaine, became Colonia Augusta Nemausus in 22 BC, following the annexation of Gallia Narbonensis in 118 BC. In 2019, preceding the artificial re-meandering of the river as a flood prevention measure, a developer-funded excavation took place in the plain of Le Vistre, 3km downstream of Nemausus. The excavation exposed a palaeo-channel, its southward migration along a 30m profile, and the remains of a Roman bridge, documenting in total over 2500

years of history, and providing an opportunity to see from a distance (both physical and temporal) not only when Nemausus started and ended, but how its environmental print extended beyond its physical boundaries. A multidisciplinary study of the palaeo-channel’s alluvium was undertaken, combining geoarchaeology, bioarchaeology, geochemistry and magnetic susceptibility. The results present a global vision of the impact of the creation and development of Nemausus on its surrounding environment.

Faunal and plant remains recovered from the alluvium shed light on agricultural practices, diet and the environmental context. The ceramic assemblages, combined with radiocarbon dates of charred plant remains, provide a chronological framework of the alluvial sequence. PXRF measurements reveal significant levels of lead enrichment in the chronostratigraphy corresponding to the Roman period, followed by their decrease after the IIIrd c. AD. Excavation data from the urban center and historical sources show extensive use of lead in early water distribution systems, with its progressive abandonment during the IInd c. AD. Taken together the geoarchaeological, bioarchaeological, geochemical, chronostratigraphic and magnetic susceptibility data show how increasing development at Nemausus polluted the city as well as the wider landscape, thus forcing us to ask where Nemausus really ends.

8 **THE TRANSFORMATION OF ROMAN COLONIAL LANDSCAPES (TARRACO, ILICI) FROM THE EARLY TO THE LATE EMPIRE: ARCHEOLOGICAL AND GEOARCHAEOLOGICAL DATA**

**Abstract author(s):** Vila, Oriol (Universitat Autònoma de Barcelona)  
**Abstract format:** Oral

From 2016 our team has developed several geoarchaeological works about the Roman landscape in two selected Roman colonial territories: the Ager Tarraconensis (Vilardida) and the Ager Ilicitanus (Alcúdia-Elche). In both areas we have identified the presence of Roman agricultural soils (and rural structures, like vineyard pits), and their connection with the settlement patterns.

The paper is focused on two main objectives.

First, the characteristics of the Roman agricultural soils (Geochemistry patterns, chronology...). In the case of Ilici, the Roman soils identified are included in the centuriatio system (the regular land division typical of the Roman colonies), and for the first time in the Roman Empire we are able to connect the particular plots with the general rural structure. In the case of Tarraco, the fields documented are adapted to the general topography of the “Vilardida” sector, with clear indicators of human fertilization.

Second, the evolution of both territories through Antiquity, showing the deep changes suffered in these landscapes from the 3rd c. onwards. We have documented periods of abandonment, indications of Pb pollution, phenomena of colluvium.... that could be linked with changes in the general settlement patterns (and also climate alterations) in both Roman colonies.

We will analyse finally this data in the framework of the so called crisis of the Roman urban system.

9 **A GEOCHEMICAL APPROACH TO SOILS FROM POST-ROMAN BURIALS (A LANZADA, NW SPAIN)**

**Abstract author(s):** García-López, Zaira - Martínez Cortizas, Antonio (EcoPast - GI-1553, Facultade de Bioloxía, Universidade de Santiago de Compostela) - López-Costas, Olalla (EcoPast - GI-1553, Archaeology, Facultade de Xeografía e Historia, Universidade de Santiago de Compostela; Archaeological Research Laboratory, Stockholm University; Laboratorio de Antropología Física, Departamento de Medicina Legal, Toxicología y Antropología Física, Facultad de Medicina, Universidad de Granada)  
**Abstract format:** Oral

Necropolises enable to approach ancient societies through the study of the human remains they contain and their funerary contexts. Most research has focused on skeletons, burial typology and grave goods, but the associated soils and sediments have been seldom considered. The interaction between human remains and sediments (i.e. diagenesis) starts after inhumation, leading to bidirectional physical and chemical changes. As a result, a new kind of soil, so-called Necrosol, develops. Morphologically described by Sobocka in 2004, the associated pedogenetic processes are only starting to be approached.

In this study we analysed 46 samples taken from longitudinal and transverse transects of two graves (one single and one double) from the post-Roman funerary area of A Lanzada (Sanxenxo, NW Spain), and 34 samples of a nearby pedo-sedimentary sequence. The dominant type of soil in the necropolis is Arenosol, developed from dune material. Samples were analysed for physical (grain size, colour) and chemical (pH; elemental composition: XRF, C and N) properties.

Principal components analysis resulted in four main components: Cp1 and Cp2 reflect pedogenic processes related with the balance between organic matter (OM) and biogenic carbonates; while Cp3 and Cp4 reflect changes in mineralogy. OM content is higher in the Necrosol (i.e., samples inside the burial), showing differences with the soils of the pedo-sedimentary sequence and also with sediments collected outside the burials. The Necrosol has a lower content of biogenetic carbonates, as a result of higher chemical alteration. In terms of mineralogy, the Necrosol shares a similar composition to that of samples from the same stratigraphic layer, i.e., same parent material. Despite most of the surrounding soils are acidic, the Necrosol is slightly to moderately alkaline (pH–8-9). The intensity and uniqueness of the Necrosol pedogenesis make this soil a valuable archive that provides complementary information for the study of skeletal remains.

THE HISPANIA PALEODIET: A REVIEW OF ISOTOPIC STUDIES ON HUMAN REMAINS FROM THE 1ST TO THE 8TH CENTURIES AD

**Abstract author(s):** García-Moreno, Carlos - Martínez-Cortizas, Antonio (EcoPast - GI-1553, Faculty of Biology, University of Santiago de Compostela) - López-Costas, Olalla (EcoPast - GI-1553, Archaeology, Faculty of Geography and History, University of Santiago de Compostela; Archaeological Research Laboratory, Stockholm University; Physical Anthropology Laboratory)

**Abstract format:** Oral

Food in antiquity is one of the booming topics in archaeology. Paleodiet can be approached through the study of stable isotopes in human remains from ancient populations. For Spain and Portugal, there are several isotopic studies dealing with diet of Roman and Post-Roman times; however, these data have yet not been explored in detail.

In this work, we review the isotopic composition ( $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  in human bone collagen) of 16 necropolises (1st-8th AD) from Spain and Portugal. Apart from the comparison of human and animal raw data, we also calculated the isotopic enrichment in humans in order to consider the necropolis baseline. The enrichment was obtained by subtracting the mean isotopic value of herbivore data (caprine+cattle of each necropolis) to the individuals' isotopic values.

Our results show a similar diet in Spain and Portugal, characterized by C3 plants with some meat/dairy products from terrestrial herbivores, which were mainly fed with C3 plants. Most of the sites are rural and located close to the sea (<50km). Although diet is not homogeneous, especially when compared with that of earlier centuries, intra-site is greater than inter-site variability. A Lanzada (NW Spain) site is exceptional since it shows a greater human consumption of C4 (millet) and marine resources. Necropolises separate slightly better when enrichments are considered, increasing the inter-site variability. Atlantic sites seem more dependent on marine resources than inland or Mediterranean ones. The  $\delta^{15}\text{N}$  values show a slight correlation to the distance to the sea, but this is less clear for  $\delta^{13}\text{C}$  values. No urban/rural or Roman/post-Roman differences were found. Our review stresses the need to increase the data for urban inland sites. Necropolis such as Emerita Augusta, where we are working at the moment, may help to fill this gap and allow a closer view to life in Hispania.

WOMEN AND CHILDREN IN ROMAN THESSALONIKI: AN INVESTIGATION OF BREASTFEEDING AND WEANING THROUGH  $\delta^{13}\text{C}$  AND  $\delta^{15}\text{N}$  INCREMENTAL ANALYSIS

**Abstract author(s):** Ganiatsou, Elissavet - Vika, Efrossini - Georgiadou, Aggeliki (Laboratory of Physical Anthropology, Department of History and Ethnology, Democritus University of Thrace) - Protopsalti, Tania (Ephorate of Antiquities of Thessaloniki City, Ministry of Culture and Sports) - Papageorgopoulou, Christina (Laboratory of Physical Anthropology, Department of History and Ethnology, Democritus University of Thrace)

**Abstract format:** Oral

The ancient city of Thessaloniki was conquered by the Romans in 168 BC and quickly became the capital of the Provincia Macedonia. Having the great advantage of being located on the sea front and along the Via Egnatia, the monumental Roman road that connected the Adriatic to the Black Sea, Thessaloniki developed into one of the most prominent trade centres of the Roman Empire. At the same time, the flourishing local artisanality and cultural countenance created the unique regional character of the city: although it was the affluent capital of the province, Thessaloniki was declared a *Liberam Civitatem* with many privileges, attested through the city's exceptional architecture and influential artistic expression.

The recent excavations of the two main necropoleis provide an unprecedented opportunity to investigate the bioarchaeological expressions of the city's distinctive cultural character as part of the Empire.

In this study, we explore the role of women in the domestic sphere as mothers and care-givers in Roman Thessaloniki. For this purpose, we employed  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  stable isotope analysis from dental increments to study breastfeeding and weaning patterns, under the premise that breastfeeding is a complex interaction between biological necessity and cultural evolution and a concept critical to the understanding of parental investment and the liminality of childhood.

Our holistic approach aims to enhance the fruitful integration of historical and bioarcheological research to better explain the cultural complexities during a time of social transformation in the south of the Roman Empire.

INSULA EXHAUSTA SILVARUM? HISTORICAL AND (GEO)ARCHAEOLOGICAL SOURCES ALLOW DOUBTING THE NARRATIVE OF THE DEFORESTATION OF ELBA ISLAND IN ROMAN TIMES

**Abstract author(s):** Becker, Fabian (Freie Universität Berlin / Physical Geography) - Eser, Raphael A. (Humboldt Universität zu Berlin / Classical Archaeology) - Schütt, Brigitta (Freie Universität Berlin / Physical Geography)

**Abstract format:** Oral

Iron production in the ancient metallurgical centre on Elba Island (Italy; 7th century BCE to 2nd century CE) was observed by various ancient writers. Diodorus (5.13.1) accounts for the smoking smelting furnaces on the island in the 1st century BCE—Strabo (5.2.6) some years later instead reports that all iron from Elba was transported to the mainland to be processed there. This contradiction (or shift) is at least since the 18th century habitually read as evidence for a “deforestation narrative”, i.e. the lack of fuelwood on the island in the 1st century BCE that resulted in the end of smelting activities. New archaeological and physio-geographical studies in the last years have challenged an “environmental” reading of Strabo’s account, though.

Proceeding from Bayesian models and cumulative probability functions of radiocarbon ages and facies interpretations from sediment sequences, we attempt to challenge the narrative. At it, we contrast (and integrate) the ancient texts, archaeological chronologies, palaeoenvironmental reconstructions (sedimentological data and pollen analysis), cliometric findings (Monte-Carlo-simulation of the fuelwood requirements based on chronology and amount of archaeometallurgical remains), and the modern interpretations of the ancient environmental conditions (as found in travelogues and scientific literature).

Although the different approaches used to analyse the situation on Elba Island rely on different spatial, temporal, and measurement scales and specificities, they appear to be closely complementary.

From the findings of the methodical triangulation, we support the following hypotheses:

1. Iron smelting on Elba had a distinct environmental impact, causing i.a. increased flood dynamics and sedimentation.
2. A complete lack of fuelwood is—however—most likely not the cause for the end of smelting on Elba, but supra-regional economic changes must be employed.
3. The deforestation narrative mainly developed in the modern period when readers of Strabo’s comment experienced contemporary deforestation and a fuel scarcity on the island.

POLLUTION’S BOOMERANG: THE IMPACT OF INCREASED ATMOSPHERIC MERCURY LEVELS IN PAST POPULATIONS

**Abstract author(s):** Álvarez Fernández, Noemi - Martínez Cortizas, Antonio (EcoPast (GI-1553), Faculdade de Bioloxia, Universidade de Santiago de Compostela) - López-Costas, Olalla (EcoPast - GI-1553, Arqueoloxía, Facultade de Xeografía e Historia, Universidade de Santiago de Compostela; Archaeological Research Laboratory, Stockholm University; Laboratorio de Antropología Física, Facultad de Medicina, Universidad de Granada)

**Abstract format:** Oral

Past human societies modified their environment in several ways; however, the extent of these modifications is, in many cases, poorly known. Under the Roman rule, extensive environmental changes took place, in the Western Empire in particular. During this historical period, atmospheric levels of several potentially toxic metals, such as mercury, increased substantially due to intense mining and metallurgy. These activities left behind their imprint in both the landscape and humans.

This research is focused on A Lanzada (NW Iberia) – a rural necropolis placed relatively far away from the neuralgic sources of mercury emissions during the Roman period. The aim was to find out variations in mercury levels in human remains. Human (cortical) bone was analysed from skeletons covering contrasting periods of atmospheric pollution (Roman, AD 1st-4th centuries, post-Roman, AD 5th -7th centuries). Samples from 3 types of bone (n=143; ribs, long bones, and crania) as well as soils/sediments associated with the burials (n=34) were analysed. Mercury concentrations in soils were below 5 ng g<sup>-1</sup>, while the average in bone was 36±52 ng g<sup>-1</sup>, making post-depositional incorporation unlikely. Concentrations were found to be significantly different between the two periods (Roman: 54 ± 60 ng g<sup>-1</sup>, post-Romans: 21±23 ng g<sup>-1</sup>), but for type of bone, sex, age, social status, or diet of the individuals they were not. Values from Roman times were moderately elevated when compared with other collections of individuals subjected to direct mercury exposition. These results agree well with the chronology of mercury pollution reconstructed from a local peatland, suggesting a predominant atmospheric source. Our study shows that, as it happens today, rural Roman populations were mostly affected by low dose chronic mercury exposure, whose levels varied with the intensity of the anthropogenic activities.

THE CHANGING LANDSCAPE OF AUGUSTAN ROME: SACRO-IDYLLIC PAINTINGS AND POLLEN EVIDENCE FROM THE GULF OF GAETA

**Abstract author(s):** Shriver-Rice, Meryl (University of Miami, Abess Center for Ecosystem Science & Policy) - Rosenthal, Crystal (University of Texas at Austin)

**Abstract format:** Oral

Sacro-idyllic fresco paintings from the homes of first century Roman elites appeared at a time of dramatic change to the topography of the Bay of Naples. Verdant woodlands and forests that once had defined Roman identity were sacrificed to expanding urban development. Roman authors praised the power of architecture over natural forces, on the one hand, while criticizing the destruction of trees, funerary gardens, and sacred groves, on the other. To date, scholarly inquiry about this distinctive genre within the history of Roman wall painting has sought to connect these paintings to Vergilian literary constructs, such as the locus amoenus, accounting for their sudden appearance in the archaeological record as a consequence of stylistic influence or elite whimsy. The aim of this paper is to examine these murals, which date from 60 BCE to the end of the first century CE, in light of recent scholarship on the regional ecology of the period, specifically palynological and climate reconstruction research from the Gulf of Gaeta. A survey of arboreal pollen data from the region indicates a rise in secondary forest species caused by human activity; while additional data regarding planktonic foraminifera and oxygen stable isotopes will help to disentangle the effects of human activity on vegetation from natural climate phenomena (Sadori et al. 2018, Sadori 2015, Di Rita et al. 2017). Sacro-idyllic imagery at such sites as Boscotrecase and Boscoreale work to resolve a crisis of Romanness faced by the Imperial elite who increasingly struggled to reconcile their urban political identities with the lost rustic virtues from which they had become estranged. In these images we witness a longing for the dignity of pastoral labor amidst a context of irreversible deforestation caused in part by Augustan agrarian reforms and the growing consumption of natural resources in a globalized world.

FUELLING ROMAN BARCINO (BARCELONA, SPAIN). THE CONTRIBUTION OF CHARCOAL ANALYSIS TO APPROACH THE CITY’S WOODLANDS EXPLOITATION FOR FIREWOOD PROCUREMENT

**Abstract author(s):** Bianco, Sabrina (Institut Català de Paleoecologia Humana i Evolució Social - IPHES-CERCA; University of Barcelona, Faculty of Geography and History) - Riera Mora, Santiago (University of Barcelona, Faculty of Geography and History) - Miró Alaix, Carme (Servei d’Arqueologia de Barcelona, Direcció de Memòria, Història i Patrimoni - ICUB)

**Abstract format:** Oral

Forested areas played an important role in past fuel supply of human settlements. In particular, in a Roman city there were many activities and facilities that demanded fuel according to a recurrent use of fire: from domestic heating and kitchens, to the the wide-spread thermae, as well as several workshops (i.e. pottery, metallurgical and glass productions), bakeries or other food processing installations, to even funerary practices as cremations.

The colony of Barcino (Barcelona) was founded at around 10 BC in the northeast of Hispania Citerior region, in a plain providing diverse natural resources. Nonetheless, archaeological evidences in the urban area and the suburbs suggest that economical activities were mostly oriented to satisfy the daily needs of the inhabitants. In this sense, pollen analyses indicate that a limited and punctual transformation of the landscape occurred during Roman times nearby the city, evidencing a predominance of woodlands over crops.

Within such a context, the aim of this presentation is to study various sites of the Roman city (domestic, productive, ritual) to identify the wood taxa used as fuel. The analysis is based on wood charcoal fragments recovered during commercial/preventive archaeological excavations carried out throughout the last decade in Barcelona. Charcoal fragments are, in fact, very durable plant material that preserves in all kind of archaeological contexts, allowing for the observation of wood anatomical characters and the subsequent taxonomical identification.

Results of charcoal analysis focusing on urban contexts, which are up-to-date quite scarce, constitute a valuable proxy to shed a light on the woodland exploitation system and fuel needs of Barcino, and to assess preferences for forest products in relation to different activities documented. At the same time, this work offers new evidence to enrich the knowledge on the urban settlement impact on the environment and the landscape evolution in the surrounding area.

THE CELESTIAL ENVIRONMENT OF THE ROMAN CITIES OF THE WESTERN PART OF EMPIRE

**Abstract author(s):** González-García, Antonio César (Institute of Heritage Sciences, Incipit-CSIC) - Garcia Quintela, Marco (Universidade de Santiago de Compostela)

**Abstract format:** Oral

One of the most prominent and characteristic elements of the Roman expansion in the West is the construction of a large number of cities, many of them built or reformed at the time of Augustus.

According to Vitruvius, the new cities had to be built taking into account the location and the prevailing winds to secure the healthiness of the new town. The ideal city followed an orthogonal grid, with streets running north-south and those perpendicular running east-west. However, according to the ‘agrimensores’, one way to achieve such orientation would be following the course of the sun by directing the streets (decumani) towards a particular sunrise.

Such practice was deeply rooted in the legendary accounts for the foundation of Rome and the ritual practices associated to them, that allegedly had an influence in the orientation cities founded or restored at that time.

In the last decade, we have measured nearly 200 towns in the ancient provinces of Germania, Gallia, Hispania, Italia, Mauritania and Africa. The idea was testing if their orientations followed random directions or if they appeared grouped towards particular directions.

In the present talk, we will review the state of the art on this research question. We will show that one of the clearest concentrations appeared for the cities built or reformed at the time of Augustus.

In order to interpret these results, we will consider new data from the centre of Rome. We will provide a new reading for some of the foundation myths of Rome in the light of this new data. Further, we will present a review of the connections of Augustus with the Sun. Finally, such lines will provide support to some of the ideas proposed to explain the peculiar orientations of the cities built at the time of Augustus in the west.

ROME TRANSFORMED: AN INTERDISCIPLINARY ANALYSIS OF POLITICAL, MILITARY AND RELIGIOUS REGENERATIONS OF THE CITY’S FORGOTTEN QUARTER C1 – C8 CE

**Abstract author(s):** Bailey, Phyllida (Newcastle University) - Azzari, Margherita (Universita’ degli Studi di Firenze) - Haynes, Ian (Newcastle University) - Liverani, Paolo (Universita’ degli Studi di Firenze) - Rosa, Carlo (S.I.G.E.A. Lazio) - Shillito, Lisa-Marie (Newcastle University)

**Abstract format:** Poster

The environmental impact of political, military and religious changes in the Eastern Caelian

ROMETRANS, the first project of its kind, aims to further our understanding of the religious, military and political transformation of the Eastern Caelian Hill from the 1st to 8th centuries C.E. During this time the area went from being home to the extravagant qua-

si-rural horti, homes to elite families, through a period when it was dominated by imperial palaces and military bases, to becoming, with the building of the world’s first cathedral and the palace of the Bishop of Rome, the centre of Catholic Christendom.

ROMETRANS integrates the study of 11 sub-surface excavated areas, the largest geo-radar and laser scanning surveys ever conducted in Rome, and an extensive programme of archival research to revolutionise our knowledge of this quarter. By incorporating archaeological, historical, topographical and geographical research, the project seeks to create a holistic 4D approach to the Eastern Caelian that goes beyond isolated studies of individual structures to understanding the evolving landscape as a whole.

Fundamental to this aim is consideration of how these changes manifested on the environment in terms of vegetation cover and land exploitation. This will be investigated through a combination of geophysical survey data, archival research, archaeobotanical and borehole analysis. Provisional archaeobotanical techniques include palynology and microcharcoal analysis with the likely addition of macro-remain identification and further micro-fossil analysis in the future depending on the nature of the deposits recovered.

This environmental investigation stands to not only significantly expand our knowledge of local and regional vegetation but will also synthesise existing data into an invaluable diachronic visualisation of the landscape in a key quarter of Imperial Rome during a time of unprecedented change that echoed throughout the Empire.

APPLIED ARCHAEOLOGY – NEW DIRECTIONS FOR THE DISCIPLINE IN A CHANGING WORLD

**Theme:** 2. Pandemics and climate change: responses to global challenges

**Organisers:** Horak, Jan (Czech University of Life Sciences in Prague, Faculty of Environmental Sciences) - Cembrzyński, Pawel (Christian-Albrechts-Universität zu Kiel, Cluster of Excellence ROOTS)

**Format:** Round table

Rapidly changing climate, growing inequalities, migration, and social changes pose a great challenge to social sciences and humanities. They are facing a question of their role and contribution in the modern world. Among them, archaeology and history seem to be especially entitled to provide insights into the modern-day problems because they study human development in long-term perspectives and the reasons behind social, economic, and environmental changes. Archaeology and history can evaluate past processes in their context and can overcome simplistic present-past analogies. They can provide such a context to other disciplines which use historical data, like environmental and life sciences, climatology, or sociology.

This session intends to create an opportunity for a meeting and discussion concentrated around a central Theme: has applied archaeology a viable potential for future? This central question leads us to a variety of important issues, like:

1. What does archaeology as a discipline need to be successfully applied?
2. Is there a viable network of specialists able to guide archaeology this way?
3. Archaeological data in other disciplines – ensuring their availability (and standardisation?), ensuring their correct interpretation.
4. Environmental and conservation issues – what people did in the past (human impact), how they dealt with the world (landscape / nature management).
5. How can archaeology contribute to present social issues like migration or racism?
6. How to correctly use historical parallels and how to deal with problems of ahistoricism (lack of correct context).

We invite to discuss and to be involved people from various fields of archaeology to share their view on applied archaeology. We believe it can create great potential for networking, sharing ideas and experiences, and looking for opportunities for future cooperation.

FROM CONTEMPORARY KNOWNs TO PAST UNKNOWNs - UNLOCKING ANCIENT HUMAN-ENVIRONMENT INTERCONNECTIONS VIA MODERN ISOTOPIC RECORDS

**Theme:** 1. Widening horizons through human-environment interconnections

**Organisers:** Winter-Schuh, Christine (Institut für Ur- und Fruehgeschichte, University of Kiel) - Eckelmann, Rebekka (Department of Cultures, Archaeology; University of Helsinki)

**Format:** Regular session

Isotopic analyses of ancient human and faunal skeletal remains has flourished over the past decade, providing new insights into how people (and animals) moved across the landscape, exploited food resources, and interacted with new environments and changing climates. However, the interpretation of stable and radiogenic isotopic data gleaned from ancient remains relies on an established understanding of the mechanics that drive isotopic variation in water, soil, plant and animal communities demonstrated in diverse ecological settings, metabolic and physiological conditions, and sample materials. This session aims to bring together isotope practitioners that explore how isotopic data from modern contexts with known/controlled conditions can help to better understand mobility, dietary intake as well as animal and agricultural management practices in the past.

More specifically this could include the following topics, but is not limited to:

- nitrogen and carbon isotopic studies of modern plant and soil systems to better understand environmental and cultural variables such as manuring, tillage, cultivation, grazing, foddering, stocking rate;

- multi-isotopic studies of modern faunal materials with known history and their diet to better understand the effect of animal physiology and diet-tissue isotopic fractionation;
- multi-isotopic studies of modern environmental samples to create local and regional isoscapes to better understand the spatial distribution of isotopes and their relevance for humans and animals in the past.

ABSTRACTS:

1 USING MODERN MULTI-PROXY ENVIRONMENTAL SAMPLES TO CONSTRAIN BIOAVAILABLE SR ISOTOPE BASELINES FOR HUMAN MOBILITY STUDIES: A CASE STUDY FROM GREECE

**Abstract author(s):** Frank, Anja (National Museum of Denmark) - Kristiansen, Kristian (University of Gothenburg) - Frei, Karin (National Museum of Denmark)

**Abstract format:** Oral

The application of Sr isotopes as a tracer for past human mobility has provided us with unprecedented insights, but hinges on the availability of bioavailable  $87\text{Sr}/86\text{Sr}$  reference baselines. To date, no consensus exists on how to establish these, which resulted in many studies using different proxies to characterise the bioavailable  $87\text{Sr}/86\text{Sr}$  signature of an area of interest. Here, we present Sr concentrations and  $87\text{Sr}/86\text{Sr}$  data for three modern environmental proxies (plants, soils and water) from the Peloponnese, Central and West Greece to constrain the differences in their respective  $87\text{Sr}/86\text{Sr}$  values and to evaluate their suitability as a baseline proxy. The  $87\text{Sr}/86\text{Sr}$  values of the different proxies appear to be dominated by geologically-sourced Sr. This is particularly true for the water samples, which record the widest isotopic range ( $87\text{Sr}/86\text{Sr} = 0.7077 - 0.7237$ ). In areas characterised by Mesozoic and Cenozoic sediments the environmental proxies record very similar  $87\text{Sr}/86\text{Sr}$  values with an average of  $0.70852 \pm 0.00174$  ( $\bar{x} \pm 2\sigma$ ) and  $0.70845 \pm 0.00085$  ( $\bar{x} \pm 2\sigma$ ), respectively. However, while the plants and soil leachate  $87\text{Sr}/86\text{Sr}$  values from these sediments are strongly correlated, they show a lower correlation to the  $87\text{Sr}/86\text{Sr}$  signatures measured for surface and spring waters. The surface and spring water samples from areas dominated by Mesozoic sediments are strongly correlated, while no correlation was observed between spring and surface waters within Cenozoic areas. Areas characterised by Palaeozoic bedrocks returned the widest range in environmental  $87\text{Sr}/86\text{Sr}$  values with an average of  $0.71427 \pm 0.01065$  ( $\bar{x} \pm 2\sigma$ ). The few samples collected from these areas are strongly correlated in their  $87\text{Sr}/86\text{Sr}$  signatures of all three proxies. The differences in proxy  $87\text{Sr}/86\text{Sr}$  signatures and correlations observed in this study emphasises the complexity behind establishing suitable baselines and highlights the importance of comprehensive, multi-proxy sampling to best characterise bioavailable Sr isotope baselines.

2 ON THE CONSTRUCTION OF MULTI-PROXY, BIOAVAILABLE SR-ISOTOPE BASELINES IN DIFFERENT TERRANES

**Abstract author(s):** Ladegaard-Pedersen, Pernille (National Museum of Denmark) - Sabatini, Serena (University of Gothenburg) - Kaul, Flemming - Frank, Anja (National Museum of Denmark) - Kristiansen, Kristian (University of Gothenburg; Globe Institute, GeoGenetics Centre) - Frei, Karin (National Museum of Denmark)

**Abstract format:** Oral

The strontium isotope tracing technique is a powerful tool for expanding our understanding of individual mobility in prehistory. The technique relies on the comparison of analysed human samples to an environmental baseline, which defines the range of bioavailable  $87\text{Sr}/86\text{Sr}$  ratios available through the food chain in the area of investigation. Thus, the constraining of the bioavailable strontium baselines influences the interpretation of who is local and who is not. These interpretations influence the archaeological narrative about prehistoric societies.

Understanding the relationship between the geological background of a specific area, the measured bioavailable strontium isotope ratios in the same area, and the strontium isotope ratios of the archaeological material under investigation is not a trivial task. As part of the “Towards a New European Prehistory” and “Tales of Bronze Age People” research projects, we are attempting to aggrandize our knowledge of this complex system by constructing Sr-isotopic baselines through a multi-proxy technique in which we collect soil, plants and water from the study areas. This talk discusses the continued challenges in the construction of bioavailable Sr-isotope baselines in different terranes by use of case studies drawn directly from ongoing research in different terranes in Scania (south Sweden), Cyprus and northern Italy.

3 STRONTIUM ISOTOPIC RATIOS ( $87\text{Sr}/86\text{Sr}$ ) FROM TOOTH ENAMEL REFLECT SEASONAL MOBILITY OF MODERN HERDS. EXAMPLES FROM THE PYRENEES (PRESENT-DAY CATALONIA)

**Abstract author(s):** Nieto-Espinet, Ariadna (Archaeology of Social Dynamics IMF-CSIC) - Trentacoste, Angela (University of Oxford) - Cardona, Gerard (Casa Ricou livestock farmer - Catalan Pyrenees) - Bòria, Artur (Catalan Goat project livestock farmer - Catalan Pre-Pyrenees) - Guimarães, Silvia (Archaeology of Social Dynamics IMF-CSIC) - García-Solsona, Ester - Torner-Pérez, Judit - Pena, Leopoldo (GRC-Geociències Marines, Dept. de Dinàmica de la Terra i de l’Oceà, Facultat de Ciències de la Terra, University of Barcelona) - Carrocio, Mateo Maria (Catalan Goat project livestock farmer - Catalan Pre-Pyrenees) - Valenzuela-Lamas, Silvia (Archaeology of Social Dynamics IMF-CSIC)

**Abstract format:** Oral

The analysis of animal mobility is key to understanding pastoral strategies and animal husbandry regimes. In the frame of the ERC-StG project ‘ZooMWest’ we conducted ethnographic work with present-day herders with organic herds in the Pyrenees. This comprised several steps: making first contacts, choosing the most relevant sheep and goat herds, accompanying and recording their transhumant and local movements, attaining agreement that the animals that could be used for the project, requesting permission from the health authorities to access the slaughterhouse, preparing the modern jaws, and finally sequentially sampling and analysing the teeth. No animals were slaughtered specifically for the purpose for the project. We respected the rhythm of each herd, and kept a fluent relationship with the herders to ensure a two-way knowledge transfer.

This work allowed us to develop a relevant baseline for both strontium and oxygen isotopic ratios ( $87\text{Sr}/86\text{Sr}$ ;  $\pm 180$ ), together with an understanding of the challenges and constraints linked to livestock mobility. Our isotopic results demonstrate that strontium isotopic ratios closely reflect mobility patterns and can be used to trace animal mobility in the past. The work also provides an opportunity for critical reflection on tooth sampling protocols and ethnographic work. Consequently, it provides highly relevant results that will help improve and refine isotopic reference for the study of mobility, and also reflects on what is involved in doing ethnographic work with modern livestock farmers beyond the scientific issues.

4 RESOLUTION AND LIMITS OF ISOTOPIC APPROACHES TO PUZZLE OUT SEASONAL HERD MOBILITY. A MODERN CASE STUDY FROM AZERBAIJAN

**Abstract author(s):** Berthon, Remi (Archéozoologie, Archéobotanique - Sociétés, Pratiques, Environnement - AASPE, MNHN-CNRS) - Giblin, Julia (Quinnipiac University, Department of Sociology, Criminal Justice and Anthropology) - Balasse, Marie - Mashkour, Marjan (Archéozoologie, Archéobotanique - Sociétés, Pratiques, Environnement - AASPE, MNHN-CNRS) - Thévenin, Michaël (Unité de recherches Migrations et société, Université de Paris-UCA-CNRS-IRD) - Fiorillo, Denis (Archéozoologie, Archéobotanique - Sociétés, Pratiques, Environnement - AASPE, MNHN-CNRS) - Ehleringer, James (University of Utah, School of Biological Sciences) - Amiri, Sarieh (Department of Archaeology, University of Tehran) - Sheikhi Sheno, Shiva (Independant scholar)

**Abstract format:** Oral

Herd mobility is a key parameter of many agro-pastoral strategies. Sequential variations of oxygen, carbon and strontium isotope ratios in ruminant teeth are commonly used for characterizing herd mobility along altitudinal gradients and across geological areas. To what extent is the variation and covariation of isotopic ratios along a tooth actually reflecting vertical and geological mobility? The interpretation of such data from archaeological material widely depends on our ability to answer to this question. Few modern baselines are available to assess covariation of oxygen and carbon isotope ratios along the tooth of modern sheep experiencing vertical mobilities. There are no such baselines for the covariation of strontium, oxygen and carbon isotope ratios. Our study aimed at analyzing the variation and covariation of isotope ratios of oxygen, carbon, and strontium in the teeth and guard hair of domestic ruminants experiencing different pastoral mobilities along altitudinal gradients and across geological areas. We sampled lower molars from one cow and 17 sheep, as well as the guard hair from five goats, all grazing in different mountainous areas of Azerbaijan (Nakhchivan, Ganja-Qazakh, and Lankaran regions) at least part of the year. Our results suggest that the covariation of the isotope ratios of oxygen and carbon allow to spot easily the specimens moving seasonally between the plains and the highlands and also between the subalpine zone and the highland meadows. To a lesser extent it is possible to sort two-staged annual mobility from four-staged annual mobility. The variations in strontium isotope ratios during the period of enamel formation also adequately reflect seasonal mobility but it deeply depends on the number of samples analyzed along the tooth crown. These results allow us to interpret isotope ratio variations in archaeological domestic ruminant teeth in order to analyze the role of herd mobilities in past agro-pastoral communities.

5 DETERMINING BIRTH SEASON USING OXYGEN ISOTOPES IN ENAMEL. A NEW MODERN REFERENCE SET FOR AUTUMN BIRTHS IN SHEEP

**Abstract author(s):** Balasse, Marie (AASPE Archéozoologie, archéobotanique : sociétés, pratiques, environnements, UMR 7209, CNRS MNHN) - Keller, Matthieu - Chemineau, Philippe (Physiologie de la Reproduction et des Comportements, UMR 7247, CNRS, INRAE, Univ Tours, IFCE) - Parisot, Sara (Unité Expérimentale de La Fage, UE0321, INRAE) - Fiorillo, Denis (AASPE Archéozoologie, archéobotanique : sociétés, pratiques, environnements, UMR 7209, CNRS MNHN)

**Abstract format:** Oral

The season of births in domestic herds determines the availability of animal production, the organization of agropastoral tasks and herds mobility on the annual scale. It can be manipulated by the herder to a certain extent and it may have been so early in

6 the history of domestication. Birth season can be investigated through the reconstruction of the seasonal cycle record in teeth, using sequential analysis of stable oxygen isotope ratios in enamel. The season of birth is then determined by comparison with modern references, i.e. oxygen isotope sequences measured in the teeth from animals of known birth season. Such works have been conducted in particular in sheep. For those, previous modern references have mostly included winter and early spring births, the season when most births occur under temperate latitudes in Europe. In order to complete the existing framework, we have built a new reference set focusing on autumn births, occurring currently in the western Mediterranean area. This new set is composed of 27 teeth (including second and third molars) from Lacause and Merinos ewes raised in southern France. We will explain how the set was constituted, present the data for autumn births, connect it to previous data for winter and early spring births on different sheep breeds, and discuss intra- and inter-breeds variability.

6 SEQUENTIAL ANALYSES OF BOVINE TOOTH DENTINE AND THE RECONSTRUCTION OF WEANING PROCESSES

**Abstract author(s):** Eckelmann, Rebekka (University of Helsinki) - Makarewicz, Cheryl - Winter-Schuh, Christine (Kiel University)

**Abstract format:** Oral

Exploitation of livestock for their dairy had a significant impact on human subsistence, providing people with a readily renewable source of fats and protein. Human manipulation of livestock for their milk can be identified by tracing changes in animal age at weaning, an ontogenetic shift associated with a decrease in trophic level that is detectable in the nitrogen isotopes of sequentially sampled herbivore dentinal collagen. However, various challenges remain with this method, in particular a loss of temporal resolution caused during sampling by cross-cutting dentine layers with different formation times. In this contribution, we explore sequential sampling methods, their effect on measured dentinal collagen d13C and d15N values, and how this impacts our interpretation of weaning patterns. We do so using cattle from northern Germany with known grazing histories, pasture stocking rates, and age at natural weaning in order to better detect human interference in calf weaning and other seasonally-related husbandry strategies.

7 MEASURING NITROGEN ISOTOPES IN TOOTH ENAMEL: A NOVEL METHOD FOR CHARACTERIZING TROPHIC POSITION IN MODERN AND ANCIENT FOOD WEBS

**Abstract author(s):** Leichliter, Jennifer (Institute of Geosciences, Johannes Gutenberg University; Max Planck Institute for Chemistry, Mainz) - Lüdecke, Tina (Max Planck Institute for Chemistry, Mainz; Senckenberg Biodiversity and Climate Research Centre, Frankfurt; Institute of Cognitive and Evolutionary Anthropology, University of Oxford) - Foreman, Alan - Duprey, Nicolas (Max Planck Institute for Chemistry, Mainz) - Winkler, Daniela (Department of Natural and Environmental Studies, University of Tokyo) - Clauss, Marcus (Clinic for Zoo Animals, Exotic Pets and Wildlife, Vetsuisse Faculty, University of Zurich) - Tütken, Thomas (Institute of Geosciences, Johannes Gutenberg University) - Martínez-García, Alfredo (Max Planck Institute for Chemistry, Mainz)

**Abstract format:** Oral

Nitrogen isotopes (d15N) are a well-established tool for investigating the trophic position of animals and humans in modern and ancient food webs. In the archeological record, d15N is usually measured in collagen extracted from bone or dentin. However, these tissues are susceptible to diagenetic alteration over time and only relatively young (<100 ka), well-preserved material is typically analyzed. In contrast, tooth enamel is less susceptible to diagenesis, but d15N analysis of enamel has long been hindered by its low nitrogen content. Here, we present a novel oxidation-denitrification method for measuring d15N in tooth enamel, which requires ≤5 mg of enamel, a 100-fold improvement in sensitivity over existing techniques.

To demonstrate that tooth enamel reflects the N isotope composition of diet, we conducted a feeding experiment with rodents (n=36), which were fed a plant-, insect- or meat-based diet. We found significant differences in enamel d15N between all dietary groups; animals which received plant-based diets had the lowest enamel d15N values (6.0 ‰), followed by insect- (7.1 ‰), then meat-based diets (7.8 ‰).

Additionally, in order to evaluate whether enamel d15N records trophic level in a natural ecosystem, we analyzed the tooth enamel of modern African fauna (herbivores, omnivores, and carnivores; n=60) and compared these data to collagen d15N values from the same individuals. We found a positive correlation between enamel and collagen d15N (R2 = 0.75; n = 34), and a trophic spacing of ~3 ‰ in enamel d15N between herbivores (6.3 ± 1.7 ‰) and carnivores (9.9 ± 2.0 ‰).

These initial datasets provide us with a framework for interpreting enamel d15N values from archeological records. The application of this novel method to diagenetically robust tooth enamel has the potential to open up new frontiers in paleodietary research by granting access to samples that were previously analytically out of reach.

8 USING MODERN MAMMAL TOOTH ENAMEL DATA TO UNDERSTAND NOVEL TROPHIC LEVEL RECONSTRUCTIONS OF EARLY PLEISTOCENE AUSTRALOPITHECUS (STERKFONTEIN, SOUTH AFRICA)

**Abstract author(s):** Lüdecke, Tina (Department of Climate Geochemistry, Max Planck Institute for Chemistry, Mainz; Institute of Cognitive and Evolutionary Anthropology, University of Oxford; Senckenberg Biodiversity and Climate Research Centre) - Leichliter, Jennifer (Department of Climate Geochemistry, Max Planck Institute for Chemistry, Mainz; Institute of Geosciences, Johannes Gutenberg University) - Duprey, Nicolas (Department of Climate Geochemistry, Max Planck Institute for Chemistry, Mainz) - Stratford, Dominic (School of Geography, Archaeology and Environmental Studies, University of the Witwatersrand) - Haug, Gerald (Department of Climate Geochemistry, Max Planck Institute for Chemistry) - Bamford, Marion (Evolutionary Studies Institute and School of Geosciences, University of the Witwatersrand) - Mathe, Jacinto - Bobe, René - Carvalho, Susana (Institute of Cognitive and Evolutionary Anthropology, University of Oxford; Gorongosa National Park) - Martinez-Garcia, Alfredo (Department of Climate Geochemistry, Max Planck Institute for Chemistry, Mainz)

**Abstract format:** Oral

Direct evidence regarding when and to what degree our early ancestors incorporated animal resources into their diets is sparse. The strongest, but indirect, evidence for meat (and bone marrow) consumption so far are cut and percussion marks on fossil bone material. Yet, meat eating has major implications for the evolution of the hominin lineage, as it is a calorie-dense, high-quality food whose consumption has been linked to significant adaptations (e.g., brain expansion). Improving capacity to identify meat consumption is crucial step towards reconstructing the timing of changes in hominin dietary behavior and to evaluate their position in (paleo) food-webs.

Nitrogen isotopes (d15N) reveal information about an individual's position in the food-web and are frequently used in conjunction with carbon isotopes (d13C) to reconstruct diet. However, d15N has thus far only been measured in specimens younger than 120,000 years, because large quantities of relatively unaltered collagen are required for analysis. Here, we utilize a novel biogeochemical method that enables us to perform high precision d15N measurements of diagenetically resistant tooth enamel (Leichliter et al., 2021).

To gain a better understanding of d15N patterns in tooth enamel in a well-constrained, modern ecosystem, we analyzed enamel of modern mammals (herbivores, carnivores and omnivores, including primates) from Gorongosa National Park, Mozambique. Then, we measured isotope values of fossil tooth enamel from a Plio-Pleistocene assemblage from southern Africa (Sterkfontein Member 4), including Australopithecus (n=7). These data represent the first d15N values measured in any early hominin. Our results indicate a large variation in d15N values among Australopithecus individuals, exceeding that observed in all other analyzed primate taxa from Sterkfontein or Gorongosa. However, the hominin values do not overlap with carnivore d15N data, pointing to a plant- rather than meat-based diet for these early Pleistocene hominins, providing a first glimpse into the trophic level of Australopithecus.

9 UNSPOOLING ENVIRONMENTAL FROM ANTHROPOGENIC INPUTS RECORDED IN HAIR KERATIN CARBON AND NITROGEN ISOTOPES OF SEMI-ARID REGION CAPRINES

**Abstract author(s):** Flohr, Pascal - Makarewicz, Cheryl (ROOTS Excellence Cluster, Kiel University; Institute for Prehistoric and Protohistoric Archaeology, Kiel University)

**Abstract format:** Oral

Establishing the intensity of ancient pasturage systems through carbon and nitrogen isotopic analyses of herbivorous animal skeletal remains offers new perspectives into nascent animal management, agro-pastoralist production, pasture access rights associated with territorialization of landscapes, and the provisioning of cities. However, establishing if variation in herbivore isotopic composition is environmental or anthropogenic in origin is particularly challenging in environments such as the southern Levant, where there are sharp differences in rainfall levels and vegetation composition over short distances. In this region, the carbon and nitrogen isotope composition of floral growth (i.e. pasture) is heavily influenced by aridity, precipitation patterns, and localized water availability, but can be further modified by, among other things, anthropogenic intensification activities involved with food production. Here, we investigate the relationship between precipitation, other aridity and water availability indicators, soil type, stocking rates, and livestock δ13C and δ15N values through isotopic analyses of hair keratin obtained from caprines grazed across the diverse landscapes of Jordan. In doing so, we seek to decouple pasturing intensity from environmental inputs in an effort to build better isotopic models for identifying pasturing dynamics in semi-arid environments.

WELL-WATERED VS. WATER-STRESSED: THE CONTRIBUTION OF MODERN C4 PLANT STABLE ISOTOPE ANALYSIS FOR RECONSTRUCTING PAST AGRICULTURAL PRACTICES IN DRYLANDS

**Abstract author(s):** Varalli, Alessandra - D'Agostini, Francesca (CaSEs Research Group, Department of Humanities, Universitat Pompeu Fabra) - Fiorentino, Girolamo (Laboratory of Archaeobotany and Palaeoecology, Department of Cultural Heritage, University of Salento) - De Benedetto, Giuseppe - Pennetta, Antonio (Laboratorio di Spettrometria di Massa Analitica ed Isotopica, Department of Cultural Heritage, University of Salento) - Madella, Marco (CaSEs Research Group, Department of Humanities, Universitat Pompeu Fabra; ICREA) - Vadez, Vincent (Institut de Recherche pour le Developpement - IRD, Université de Montpellier – UMR DIADE, BP; International Crops Research Institute for Semi-Arid Tropics - ICRISAT) - Lancelotti, Carla (CaSEs Research Group, Department of Humanities, Universitat Pompeu Fabra; ICREA)

**Abstract format:** Oral

Charred seeds from archaeobotanical assemblages are routinely investigated to reconstruct past agricultural management. In arid environment, C4 plants like millets are widespread as their physiology makes them tolerant to drought. Because of this, it is generally assumed that C4 plants' isotopic values do not vary with different hydrological conditions. Nevertheless, recent research based on modern plants has found correlations between carbon and nitrogen values and watering conditions in some species of millets (e.g. *Setaria italica*). Our aim is to define the isotopic variability in selected species of C4 crops grown under different water treatments in order to deliver a reliable framework to reconstruct past water management based on experimental analyses.

Within the framework of RAINDROPS (ERC-Stg 759800), we conducted two different controlled experiments on two C4 species, *Pennisetum glaucum* and *Sorghum bicolor*. The plants were grown under different water treatments and all the physiological parameters (e.g. water transpired) were monitored. In the first experiment, the well-watered plants were irrigated weekly to maintain 80% of the soil field capacity while the water-stressed plants received water only until the flowering. In the second experiment, plants were irrigated following four water-stress treatments, stopping the irrigation at the second, fourth, sixth and eighth week from the sowing. We then compared  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  in all plant grains in order to estimates ranges of variability.

The preliminary results show that pearl millet and sorghum react differently to the diverse hydric conditions. *Sorghum* (NADP-ME) is more sensitive to irrigation than pearl millet (NAD-ME), likely because of the different physiology. In both experiment,  $\delta^{13}\text{C}$  in sorghum is positively correlated with water availability, while  $\delta^{15}\text{N}$  does not show any correlations. Concerning pearl millet, no correlations are evident any of the experiments. This allows for considering sorghum as an eventual good proxy for reconstructing agricultural strategies in the past.

STABLE ISOTOPE COMPOSITION OF WEED PLANT CARBONATE AS A PALEOENVIRONMENTAL INDICATOR FOR PAST AGROECOSYSTEMS

**Abstract author(s):** Pustovoytov, Konstantin (Institute for Archaeological Science and Senckenberg Center for Human Evolution and Palaeoenvironment, Tübingen University; Institute of Oil and Gas, Yugra State University) - Riehl, Simone (Institute for Archaeological Science and Senckenberg Center for Human Evolution and Palaeoenvironment, Tübingen University)

**Abstract format:** Oral

Human-ecosystem interactions in the past remain poorly understood because of the scarcity of accurate paleoenvironmental records on ancient agroecosystems. Here we report about the potential of plant carbonate in the weed taxon *Lithospermeae* (fam. *Boraginaceae*) as a local paleoenvironmental indicator of growing conditions on ancient arable fields.

The tribe *Lithospermeae* includes the genera *Lithospermum* and *Buglossoides*, which are typical representatives of weed flora with-in a broad range of climates, but especially common in the Mediterranean regions. These plants accumulate biogenic carbonate in tissues of their fruits during one vegetative season. The ripe fruits represent small (2-5 mm in length) nutlets with calcareous pericarps. Under arid-semiarid conditions, they can remain well-preserved over millennia in cultural layers and sediments. Ancient nutlets of *Lithospermeae* widely occur in archaeobotanical spectra of Eurasia and both Americas. A comparison of  $^{14}\text{C}$  ages of fruit carbonate with numerical chronology shows that biogenic  $\text{CaCO}_3$  of the taxon can be successfully dated with radiocarbon.

In this study, we use modern  $\delta^{18}\text{O}$  and  $\delta^{13}\text{C}$  values of plant carbonate sampled in herbaria and from experimentally grown plants to demonstrate sensitivity of the  $\text{CaCO}_3$  fraction to ambient factors. Our data suggest that the oxygen isotope fractionation in fruit carbonate is relatively low ( $1000\ln\alpha = 4.72$ ). Furthermore, its  $\delta^{18}\text{O}$  is clearly sensitive to amount of atmospheric precipitation for the warm season ( $r_s$  and  $R^2$  about -0.70 and 0.45 respectively), but shows a lower degree of correlation to air temperatures. The indicative role of  $\delta^{13}\text{C}$  of fruit carbonate is less evident and may be linked to specific physiology of photosynthesis of *Lithospermeae*. The findings of this study thus demonstrate potential possibilities of fruit  $\text{CaCO}_3$  as a specific paleoenvironmental indicator, primarily for problematic issues of moisture availability in the past.

EFFECTS OF MARINE BIOFERTILISATION ON CELTIC BEAN CARBON, NITROGEN AND SULPHUR ISOTOPES: IMPLICATIONS FOR RECONSTRUCTING PAST DIET AND FARMING PRACTICES

**Abstract author(s):** Gröcke, Darren - Church, Mike - Treasure, Edward - Gron, Kurt (University of Durham)

**Abstract format:** Oral

The application of fertilisers to crops can be monitored and assessed through stable isotope ratios. However, the effect of marine biofertilisers (e.g., fish, macroalgae/seaweed) on crop stable isotope ratios has been rarely studied, despite widespread archaeo-

logical and historical evidence for the use of marine resources as a soil amendment. A heritage variety of Celtic bean, similar in size and shape to archaeobotanical macrofossils of *Vicia faba* L., was grown in three 1×0.5m outdoor plots under three soil conditions: natural soil (control); natural soil mixed with macroalgae (seaweed); and 15cm of natural soil placed on a layer of fish carcasses (Atlantic cod). These experiments were performed over two growing seasons in the same plots. At the end of each growing season, the plants were sampled, measured and analysed for carbon, nitrogen and sulphur stable isotope ratios. The bean plants freely uptake the newly bioavailable nutrients (nitrogen and sulphur) and incorporate a marine isotopic ratio into all tissues. Bean nitrogen-isotope values average 0.9‰ in the control experiment compared with 2.5‰ in the macroalgae crop. The cod fish crop exhibited a range between 8‰ to 17‰. Sulphur isotope values averaged 6‰ in the control, compared with 15.5‰ in the macroalgae crop and 10.5‰ in the cod fish crop. The beans became more  $^{13}\text{C}$ -depleted due to crop management practices. Humans and animals consuming plants grown with marine biofertilisers will incorporate a marine signature. Isotopic enrichment in nitrogen and sulphur using marine resources has significant implications when reconstructing diets and farming practices in archaeological populations. Additional archaeological bean isotope data from coastal and in-land sites will be presented as examples.

SEAWEED FERTILISATION AND CONSUMPTION: MODERN REFERENCE DATA OF FERTILISED BARLEY AND BONES AND TEETH OF SEAWEED-EATING SHEEP

**Abstract author(s):** Blanz, Magdalena (University of Vienna, Austria; University of the Highlands and Islands) - Mainland, Ingrid (University of the Highlands and Islands) - Ascough, Philippa (Scottish Universities Environmental Research Centre) - Taggart, Mark (University of the Highlands and Islands) - Richards, Michael (Simon Fraser University) - Wishart, John - Martin, Peter (University of the Highlands and Islands) - Raab, Andrea - Feldmann, Jörg (University of Graz)

**Abstract format:** Oral

Historical evidence indicates the use of seaweed as a fertiliser and as forage for domesticated animals to have been common in coastal areas. However, until recently it has been unknown how fertilisation of terrestrial crops with seaweed affects  $\delta^{13}\text{C}$ ,  $\delta^{15}\text{N}$  and  $^{87}\text{Sr}/^{86}\text{Sr}$  values. Similarly, the effects of seaweed consumption on bone collagen  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  had not been studied.

To further study the effects of fertilisation, a field trial was undertaken where bere barley was fertilised with seaweed (25t/ha and 50t/ha). Analysis of the crop showed  $\delta^{13}\text{C}$  values to be unaffected, but  $\delta^{15}\text{N}$  were elevated by  $0.6\pm0.5\text{‰}$  (average $\pm1\sigma$  for five replicate plots) in grain, and  $1.1\pm0.4\text{‰}$  in straw due to seaweed fertilisation. Sr concentrations were elevated by a factor of 1.3 in seaweed fertilised grain, but no significant difference was found for straw.

Additionally, bone collagen  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  of modern seaweed-eating and grass-eating sheep (C3 vegetation) as well as terrestrial vegetation and seaweed from the Orkney islands were analysed. For the seaweed-eating sheep  $\delta^{13}\text{C}$  values were significantly elevated compared to grass-eating sheep, ranging from  $-25.1\text{‰}$  in a terrestrially feeding sheep and up to  $-10.7\text{‰}$  in a seaweed-eating sheep. Since collagen and tooth enamel bulk  $\delta^{13}\text{C}$  values suffer from equifinality issues when C3, C4 and marine plants are present, an alternative method to identify seaweed consumption would be beneficial for aeras where C4 plants grow. For this reason trace elemental analysis of modern sheep enamel was undertaken, which revealed significantly lower lg(Ba/Sr) values for seaweed-eating sheep than terrestrial feeding sheep. Trace elemental ratios may thus be useful to support studies of isotope ratios.

The results of this work show that the study of modern reference materials is necessary for the correct interpretation of isotope ratios from archaeological material and will aid the identification of seaweed consumption by herbivores globally.

MULTI-ISOTOPIC APPROACH OF MODERN ENVIRONMENTAL SAMPLES FROM THE BALTIC COAST REVEALS INSIGHTS INTO SEA SPRAY MECHANISMS

**Abstract author(s):** Göhring, Andrea (Ludwig Maximilian University, Faculty of Biology, Department of Biology I, Anthropology and Human Genomics) - Hölzl, Stefan (RiesKraterMuseum Nördlingen) - Mayr, Christoph (Friedrich Alexander University Erlangen-Nuremberg, Institute of Geography; Ludwig Maximilian University Munich, Faculty of Geosciences, Department of Earth and Environmental Studies) - Strauß, Harald (University of Münster, Institute of Geology and Palaeontology)

**Abstract format:** Oral

Isotopic analyses on skeletal remains from archaeological sites close to the sea are hampered by the so-called sea spray effect. This effect causes a marine signal in terrestrial environments in all trophic levels, including humans. This results in a misleading isotopic fingerprint, if the data were not corrected for the sea spray effect. However, so far, the impact of the sea spray effect can only be mathematically approximated. Moreover, we do not know how and in what magnitude the sea spray actually enters the food chain in the different isotopic systems.

Therefore, modern environmental samples (plant, soil, water) were collected along the Baltic coast three times a year. In addition, greenhouse samples treated with known mineral salt concentrations or seawater solutions were analyzed for comparison. A multi-isotope approach including  $\delta^{13}\text{C}$  of cellulose (plant),  $\delta^{18}\text{O}$  of cellulose (plant) and inorganic sulfate (plant, soil, water),  $\delta^{34}\text{S}$  of total sulfur (plant), inorganic sulfate (plant, soil, water), and organic sulfur (plant), as well as  $^{87}\text{Sr}/^{86}\text{Sr}$  of the inorganic components of plant, soil, and water was performed.

The influence of the sea spray can be clearly seen in the seven isotopic dimensions. The impact of the sea spray on the isotopic systems under study differs due to different biochemical pathways. The isotopic data also show remarkable seasonal variability between spring, summer, and autumn samples, partly due to temperature effects as well as prevailing wind directions. Moreover,

the sea spray differs between sites and distance from the coast. The influence of the sea spray on the different isotopic systems is evidenced using cluster analysis.

Modern environmental samples can help to solve the problem of the sea spray effect on stable isotopes of archaeological skeletal remains. If we know the impact of sea spray on the isotopic fingerprints of individuals, the data can be interpreted correctly.

PRESERVATION OF 87SR/86SR SIGNATURES IN EXPERIMENTALLY HEATED HARD CLAMS: IMPLICATIONS FOR SHELL MIDDEN RESEARCH

**Abstract author(s):** Höpker, Sebastian (Leibniz Centre for Tropical Marine Research - ZMT - GmbH, Bremen, Germany; Faculty of Geosciences, University of Bremen; Environmental Research Institute, School of Science, Faculty of Science and Engineering, University of Waikato) - Wu, Henry (Leibniz Centre for Tropical Marine Research - ZMT - GmbH) - Lucassen, Friedrich (Faculty of Geosciences and MARUM - Center for Marine Environmental Sciences, University of Bremen) - Merschel, Peter (Leibniz Centre for Tropical Marine Research - ZMT - GmbH, Bremen, Germany; BDG Berufsverband Deutscher Geowissenschaftler e.V.) - Kasemann, Simone (Faculty of Geosciences and MARUM - Center for Marine Environmental Sciences, University of Bremen) - Westphal, Hildegard (Leibniz Centre for Tropical Marine Research - ZMT - GmbH; Faculty of Geosciences, University of Bremen)

**Abstract format:** Oral

Archaeological shell middens present valuable archives of past human societies and the environment that they lived in. Much of the information gained from midden deposits relies on geochemical analyses of individual components, such as the skeletal remains of shellfish and fish. Sr isotope ratios ( $^{87}\text{Sr}/^{86}\text{Sr}$ ) are of increasing interest to archaeological enquiries as a means of geochemical tracing of dietary habits and migration patterns, and measured in midden-derived biogenic carbonates can serve as a proxy of precipitation and runoff in the respective organisms’ aquatic habitats. However, when using geochemical information from midden constituents, a potential alteration of the material’s original chemical composition due to pre-depositional processing or cooking practices by historic communities needs to be considered. In this regard, the stability of Sr isotopic signatures with respect to such treatments has not been affirmed to date, which is required for any confident  $^{87}\text{Sr}/^{86}\text{Sr}$ -based interpretations. In this study, we assessed the preservation potential of  $^{87}\text{Sr}/^{86}\text{Sr}$  by re-analysing 23 cultured hard clams from the experimental study by Müller et al. (2017). Our findings suggest that none of the three simulated prehistoric cooking practices (boiling, roasting, burning) alter the original  $^{87}\text{Sr}/^{86}\text{Sr}$  signature ( $0.70918 - 0.70920$ ;  $p = 0.26$ , one-way ANOVA), despite significant mineralogical changes and previously reported implications for other geochemical properties. Based on our results, we suggest that carbonate  $^{87}\text{Sr}/^{86}\text{Sr}$  measured in midden constituents can be expected to present the original isotopic composition, which in turn can be linked to past runoff patterns and hydroclimate, and foraging habits of human settlements.

STABLE OXYGEN ISOTOPE ANALYSIS ON PATELLA DEPRESSA REVEALS SEASONAL MARINE MOLLUSC EXPLOITATION PATTERNS IN N IBERIA BY MESOLITHIC FORAGERS

**Abstract author(s):** García-Escárzaga, Asier (Max Planck Institute for the Science of Human History; Universidad del País Vasco) - Gutiérrez-Zugasti, Igor (Instituto Internacional de Investigaciones Prehistóricas de Cantabria, Universidad de Cantabria) - Cuenca-Solana, David (Instituto Internacional de Investigaciones Prehistóricas de Cantabria, Universidad de Cantabria; Centre de Recherche en Archéologie, Archéosciences, Histoire - CReAAH) - González-Morales, Manuel (Instituto Internacional de Investigaciones Prehistóricas de Cantabria, Universidad de Cantabria) - Ilgner, Jana (Max Planck Institute for the Science of Human History) - Roberts, Patrick (Max Planck Institute for the Science of Human History; School of Social Sciences (University of Queensland))

**Abstract format:** Oral

Investigations conducted during last few decades in the Cantabrian region (N Iberia) have greatly increased our knowledge about littoral resource exploitation patterns during the Mesolithic period (ca. 10,500 - 6,700 cal BP). Stable oxygen isotope ratios ( $\delta^{18}\text{O}$ ) can act as powerful recorders of the seasonal seawater temperature variations experienced by a mollusc in the past, enabling us to accurately establish the period of the year when it died/was collected by humans. Recent studies applying this methodology to mollusc shells have allowed us to properly determine seasonal exploitation patterns of the topshell *Phorcus lineatus* (da Costa, 1778) and the limpet *Patella vulgata* Linnaeus, 1758 in N Spain. Results obtained so far have reported differences in collection strategies depending on the species, with *P. lineatus* collection patterns being driven by a cost-benefit principle. However, while the limpet *Patella depressa* Pennant, 1777 is one of the most common mollusc species found in Holocene archaeological assemblages along the Atlantic façade of Europe, seasonal collection patterns in relation to this species have been under-studied. Here, we apply stable oxygen isotope analyses to *P. depressa* shells recovered from the shell midden site of El Mazo cave (Asturias, Spain) to determine if there are seasonal patterns in its exploitation by humans. We also undertake a modern experimental programme, collecting *P. depressa* individuals all year round from N Iberia, in order to establish whether observed seasonality (if any) is likely to have caused by cost-benefit principles or other cultural factors. The results obtained allow us to better understand patterns of littoral resource exploitation and overall subsistence of some of the last specialized hunter-fisher-gatherers in western Europe.

ASSESSING THE IMPACT OF MAJOR CLIMATIC AND/OR ENVIRONMENTAL EVENTS ON HUMAN CULTURE AND SUBSISTENCE

**Theme:** 2. Pandemics and climate change: responses to global challenges

**Organisers:** Glykou, Aikaterini - Lidén, Kerstin (Archaeological Research Laboratory, Stockholm University) - López-Costas, Olalla (EcoPast, Area of Archaeology, Dpto. History, Universidade de Santiago de Compostela) - Jordan, Peter (Department of Archaeology and Ancient History, Lund University) - Uchiyama, Junzo (Sainsbury Institute for the Study of Japanese Arts and Cultures, University of East Anglia and Center for Cultural Resource Studies, Kanazawa University)

**Format:** Regular session

This session will examine the extent to which archaeologists can reconstruct the impact of major climatic and/or environmental events on humans and their environment and the extent to which past societies were able to respond, culturally and economically, to such changes during the Late Pleistocene and the Holocene. Sudden climatic events and weather extremes probably had significant societal impact, as they directly influence the food resources, plants and animals, upon which human livelihood depend. Climatic shifts and environmental change have the potential to be major drivers of societal change but this is poorly understood in practice. Additionally, both short-term catastrophic environmental disasters and long-term protracted and deep-seated climatic change may provoke different responses from different human societies. Major global environmental events such as the Preboreal Oscillation at 11.3 ka, the 8.2 ka cold event, the 4.2 ka aridification event and the 536 AD dust-veil event have been associated with cultural shifts in different regions worldwide. It is highly likely that there was variability in the extent to which different societies in different times and places were able to respond. Expression of such responses could be high mobility, relocations, large-scale abandonments, or adaptation and resilience. Cultural adaptation, however, is the most challenging to establish in the archaeological record. This session aims to bring together researchers who are interested in discussing how we can provide evidence-based data on past human adaptive strategies to climate/environmental change. This session is open for papers presenting various methodological approaches that use a multi-proxy approach to reconstruct past environmental impacts and the human cultural responses, from archaeology, archaeobotany, bioarchaeology, zooarchaeology, geoarchaeology.

ABSTRACTS:

CONVERGENT CATASTROPHE? THE COMBINED HUMAN IMPACTS OF THE 8.2KA EVENT AND THE STOREGGA TSUNAMI ON MESOLITHIC FORAGERS IN WESTERN DENMARK

**Abstract author(s):** Andreassen, Kathrine - Riede, Felix (Department of Archaeology and Heritage Studies, Aarhus University)

**Abstract format:** Oral

The so-called ‘8.2ka event’ arguably had a major impact on Northern Hemisphere climate. In Denmark, it appears to have had an influence on lakes and rivers, which were essential landscape features for contemporaneous foragers. Around the same time as the 8.2ka event, the Storegga tsunami affected the North Sea Basin. While there is considerable debate about the loss of lives and livelihoods associated with this event, we here explore whether it, in combination with broadly coincidental climate change, lead to changing land-use amongst contemporaneous Maglemosian foragers in western Denmark. Drawing on theoretical approaches from environmental anthropology, our focus is in particular on sites in the catchment area of the River Gudenå. We review their numerical and techno-typological dating as well as associated evidence for environmental changes around the 8.2ka event horizon, and explore the possibility of a major reorientation from inland to coastal, and from networks reaching westwards towards networks with a preferential eastern orientation.

COMPARING HUMAN RESPONSE TO THE ONSET OF THE HOLOCENE IN NORTHERN GERMANY AND DENMARK

**Abstract author(s):** Weber, Mara-Julia - Eriksen, Berit Valentin - Grimm, Sonja B. - Groß, Daniel (ZBSA - Centre for Baltic and Scandinavian Archaeology; CRC 1266 “Scales of Transformation”) - Krüger, Sascha - Mortensen, Morten (National Museum of Denmark) - Wild, Markus (Cluster of Excellence “ROOTS”; CAU Kiel)

**Abstract format:** Oral

The Pleistocene-Holocene transition is well suited to study how major climatic shifts were reflected in the composition of floral and faunal communities and how prehistoric societies responded to these climatic and/or environmental changes due to its significant impact on the environment. After a long phase of colder climate in the Younger Dryas, the onset of the Holocene is marked by a rapid rise of temperature, which was in some areas only interrupted by the short-term climatic and environmental event of the Preboreal Oscillation.

We jointly investigate the interrelationship of changes in the technical, economic and social behaviour of the Ahrensburgian and early Maglemosian hunter-gatherer groups on the one hand and the climatic as well as environmental transformations from the Younger Dryas to the early Holocene on the other hand. For this purpose, archaeological studies of the material culture are interlinked with archaeozoological and palaeobotanical analyses. In addition, supposed Lateglacial and Early Holocene bone and antler artefacts from Denmark have recently been reviewed and radiocarbon dated.

3

### SURVIVING IN THE ASHES: A PRELIMINARY ASSESSMENT OF SOCIO-ECOLOGICAL RESPONSES TO A “SUPER-ERUPTION” IN FORAGING SOUTHWEST JAPAN (7.3KA CAL BP)

**Abstract author(s):** Uchiyama, Junzo (Sainsbury Institute for the Study of Japanese Arts and Cultures; Center for Cultural Resource Studies, Kanazawa University) - Jordan, Peter (Department of Archaeology and Ancient History, Lund University) - Isaksson, Sven (Archaeological Research Laboratory, Department of Archaeology and Classical Studies, Stockholm University) - Kuwahata, Mitsuhiro (Advanced Asian Archaeological Research Center, Kyushu University)

**Abstract format:** Oral

Major volcanic eruptions are one of the most devastating and unpredictable events for all societies past and present. Although major progress has been made by archaeologists in understanding volcanic impacts on past societies, almost all this work has focused on urban or settled agricultural societies. In contrast, there is a major gap in knowledge about how forager communities were able to respond and recover, though important work has been conducted in northern Europe. In this paper we aim to add to this emerging knowledge base, and present a case-study from the Pacific “Ring of Fire” – we aim to understand the extent to which Jōmon Hunter-Fisher-Gatherers were impacted by the Kikai-Akahoya (K-Ah) super-eruption of 7.3ka cal BP, by looking at devastation, resettlement and recovery with a long-term perspective.

The K-Ah eruption was equivalent to VEI 7 and one of the top 6 large eruptions in the Holocene, which occurred in the ocean off the coast of Southern Kyushu. It produced more than 100 km<sup>3</sup> tephra which covered a 2 million km<sup>2</sup> area of Northeast Asia. Tanegashima Island, which is located only about 50 km to the east of the eruption centre, was exposed to the full force of the pyroclastic flow. Everything was destroyed and the entire landscape decked with metres of ash. But within a few centuries, people were back and recolonised the island. We use the data of site location, lithic tool, and food residue analysis as well as paleo-ecological information to explore how people adapted to the new environments and estimate the long-term influence of the eruption.

We are in the process of launching a larger interdisciplinary project that will investigate K-Ah impacts and socio-ecological responses across a transect of local and more distant sites and regions.

4

### DEALING WITH THE IMPACT OF THREE MAJOR ENVIRONMENTAL EVENTS ON PREHISTORIC COASTAL SOCIETIES AND THEIR MAIN PREY SPECIES

**Abstract author(s):** Liden, Kerstin - Glykou, Aikaterini - Eriksson, Gunilla - Isaksson, Sven (Archaeological Research Laboratory)

**Abstract format:** Oral

How did humans use culture as a means to handle sudden environmental change, and can we detect common patterns of human behaviour in prehistoric coastal societies in the Baltic Sea area? Our project is focusing on three major global environmental events that are likely to have affected both humans and marine mammals, and consequently should be possible to trace in the archaeological record: the 8200 cal BP cold event in the Mesolithic (the 8.2 event), the 4200 cal BP aridification event in the Neolithic (the 4.2 event) and the 536 AD dust-veil event in the Migration Period. These events have been associated with cultural shifts in different regions worldwide, but not previously in the Baltic Sea Region. Although there are detailed records on both geological/environmental processes and the archaeological cultural contexts, respectively, in this area, the impact of climatic change on cultural shifts has not been previously taken entirely into consideration. By integrating studies on archaeology, bioarchaeology, marine mammal ecology and environment, the project will provide new data on how the prehistoric environment was entangled with both human culture and marine mammal ecology, affecting each other both ways.

The project will address the following questions:

1. How did humans deal culturally with environmental/climatic change?
2. Is it possible to identify temperature fluctuations caused by such events in skeletal remains of humans and seals?
3. Can we recognize dietary shifts and mobility triggered by environmental/climatic change?

5

### SEALS ON THE ICE: THE IMPACT OF CLIMATIC CHANGE ON THE BALTIC SEA HARP SEALS AND ON HUMAN SUBSISTENCE

**Abstract author(s):** Glykou, Aikaterini (Archaeological Research Laboratory, Stockholm University) - Lõugas, Lembi (Archaeological Research Collection, Tallinn University) - Piličiauskienė, Giedrė (Department of Archaeology, Vilnius University) - Schmölcke, Ulrich (Centre for Baltic and Scandinavian Archaeology - ZBSA, Schleswig) - Eriksson, Gunilla - Lidén, Kerstin (Archaeological Research Laboratory, Stockholm University)

**Abstract format:** Oral

This paper will explore climatic/environmental and human impacts on a temperature sensitive species, the harp seal (*Pagophilus groenlandicus*), which occurred frequently in the Baltic Sea during the mid-Holocene and became extirpated during the late Holocene. Seal hunting was of great economic significance for the coastal societies of the Baltic Sea mainly during the mid-Holocene

and to a lower extent during the late Holocene. One of the most hunted seal species in this area was the harp seal, which is commonly found in archaeological assemblages. Harp seal is cold adapted and today, it has a subarctic distribution with breeding populations in the White Sea, the Jan Mayen Islands and around Newfoundland. Harp seals are considered to be a good paleoclimate indicator as they are highly depended on pack ice and are highly sensitive to any changes in their habitat that affect breeding and foraging patterns. We combined radiocarbon dating of harp seal bones with zooarchaeological, palaeoenvironmental, stable isotope and strontium isotope data to reconstruct the presence of harp seals in the Baltic Sea during the Holocene. Our data show that the harp seal bred in the Baltic Sea already during the Holocene Thermal Maximum (HTM), the population declined or even went locally extinct around the 4.2 event, and final extirpation coincided with the onset of the Medieval Warm Period. Further, this paper will discuss how temperature sensitive species can be used as proxies to explore impacts of climatic/environmental change on human subsistence.

6

### THE BALTIC GREY SEAL – A HISTORY OF PRESENCE AND ABSENCE

**Abstract author(s):** Bro-Jørgensen, Maiken (Archaeological Research Laboratory, Department of Archaeology and Classical Studies, Stockholm University; Section for Evolutionary Genomics, GLOBE Institute, University of Copenhagen) - Ahlgren, Hans - Glykou, Aikaterini (Archaeological Research Laboratory, Department of Archaeology and Classical Studies, Stockholm University) - Schmölcke, Ulrich (Schleswig-Holsteinische Landesmuseen) - Angerbjörn, Anders (Department of Zoology, Stockholm University) - Olsen, Morten (Section for Evolutionary Genomics, GLOBE Institute, University of Copenhagen) - Lidén, Kerstin (Archaeological Research Laboratory, Department of Archaeology and Classical Studies, Stockholm University)

**Abstract format:** Oral

The grey seal has been part of the Baltic fauna since at least 9000 BP and were together with other seal species an important resource for coastal hunter-gatherer societies. Large numbers of bone remains bear witness to the intensity of seal hunting and seal bones are plentiful at the Swedish site Stora Förvar (Gotland) and the German site Neustadt. We generated 69 mitochondrial control regions from ancient grey seals from Stora Förvar and Neustadt and applied radiocarbon dating on the same bone material in order to investigate genetic changes in the Baltic grey seal population through time and in response to known climatic events. Based on the radiocarbon dates, the disappearance of grey seals from Stora Förvar in the Mesolithic was not directly link-able to the 8.2 ka cold event, and might instead reflect intensive hunting prior to this climatic event. The genetic results show that a population replacement took place some time between the Early Neolithic and the Bronze Age. As this time range overlap with the 4.2 ka aridification event, it is possible that a prior population size reduction or even local extinction of grey seals in the Baltic Sea can be linked to this climatic event. The new genetic variation, which appeared in the Bronze Age, is similar to that of modern Baltic grey seals. The majority of the mitochondrial haplotypes from the Mesolithic and Neolithic are not found among modern and historical data, and are therefore to be considered extinct today.

7

### A LONG TRANSITION: THE END OF LATEGLACIAL AND THE BEGINNING OF THE HOLOCENE AT COVES DE SANTA MAIRA (ALICANTE, SPAIN)

**Abstract author(s):** Conesa, Margarita - Carrión Marco, Yolanda - Pérez Jordà, Guillem - Martínez Varea, Carmen M<sup>a</sup> - Morales Pérez, Juan V. - Balcázar Campos, Nicole - Miret Estruch, Carles - Aura Tortosa, J. Emili (Universitat de València)

**Abstract format:** Oral

The Lateglacial to early Holocene transition includes climatic events of high and medium magnitude, which ended up defining the current Mediterranean landscapes. Santa Maira sequence covers this period and analyses of different materials have allowed for the reconstruction of the landscape and human strategies for raw materials exploitation.

Wood charcoal analysis shows that the most exploited tree taxa are both deciduous and evergreen *Quercus* types (oak) together with *Juniperus* sp. (juniper) throughout the sequence. As far as the plant composition is concerned, there were no major changes. However, the frequencies of some taxa change noticeably, thus indicating a shift in the woodland structure and/or in the plant resources management strategies. Large numbers of macroremains of fruits (*Quercus* sp., *Sorbus* sp., *Olea* sp. and *Vitis* sp.) were also found, but a significant quantity of legumes together with a few grass seeds have also been identified.

Regarding the exploitation of mammals, no abrupt changes are identified throughout the sequence. However, a trend towards diversification is observed, with a greater presence of taxa which in turn represent a greater relative weight within the samples. This trend starts in the Lateglacial and can be linked to ecological changes, particularly to afforestation processes. The evolution of lithic assemblages during this period is also characterised by continuity (local and regional raw material procurement, production objectives), although some changes occur (exploitation modalities and retouched tools). However, this did not affect the essential purposes of lithic production: microlaminar tools intended for creating composite and household tools linked to maintenance and consumption.

It can be inferred that there was a long process of change in the management of forest resources and raw materials, which began ca. 14.5 ky cal BP and lasted until the appearance of the Mesolithic period ca. 10.5 ky cal BP.

8 **CLIMATIC IMPACT ON THE CULTURAL DEVELOPMENT IN THE VOLGA AND KAMA BASIN**  
**Abstract author(s):** Vybornov, Alexander (Samara State University of Social Sciences and Education) - Kulkova, Marianna (Herzen University)

**Abstract format:** Oral

The territory of the Volga and Kama basin is presented by different landscape zones: semi-desert of the Northern Cis-Caspian, steppe zone in the Low Volga basin, forest-steppe of the Middle Volga basin and forest zone in the Kama basin. Based on the investigations of last years, the climatic changes around 6,2 ka calBP and cultural transformations in this time should be considered as well. In the Povolzhye in this time the Khvalinian culture was developed. After the abrupt climatic event at 6,2 ka calBP, the sites of this culture disappeared from this territory. Some hiatus can be noticed between the Khvalinian culture and the early stage of Yamnaya culture. We can suggest that this connects with strong aridization at this time. In the forest area of Povolzhye at 6,2 ka, BP the sites of Krasnomostovskogo type were open. They are the results of the syncretism of two cultures and reflect the transition from Neolithic to Eneolithic. In the forest zone of the Upper Povolzye, the protovolosoovsky type of sites demonstrates the same process. In the forest zone of the Kama basin, the sites of Novoilinskaya culture appeared at 6,2 ka calBP. The changes in technology and typology of the stone tools and ceramics are registered on the sites of these cultures. This culture was developed on the base of the Kamskaya culture and reflects the transition to the Eneolithic. So, the aridization around 6,2 ka cal BP influenced the cultural processes on the territory of the Volga and Kama basin, but there have features in these transformations in each landscape zone. The most mosaic process has occurred in the forest-steppe of Povolzhye. The cultural monotony characterizes the sites of Kama basin. But all these features predict the transition stage to the Eneolithic period.

9 **ENVIRONMENTAL CHANGE AND HUMAN RESPONSE IN A THESSALIAN BASIN LANDSCAPE SOUTH OF MT OLYMPUS: A DIACHRONIC STUDY (6500-3300 BC)**  
**Abstract author(s):** Reingruber, Agathe (FU-Berlin) - Toufexis, Giorgos (Ephorate of Antiquities of Larissa)

**Abstract format:** Oral

In a joint German-Greek project, intensive surveys were carried out between 2017 and 2020 in the basins of Sykourio and Elateia (north-eastern Thessaly), an area of about 15 x 5 km. In the process, we were able to re-locate already known prehistoric sites as well as discover new ones. The archaeological and geographical information collected was uploaded in a Geographical Information System (GIS) and evaluated diachronically. In addition, emphasis was placed on describing the surroundings of the various sites, be they tell sites (magoules), flat sites, hilltop settlements or limited assemblages of finds. Their proximity or distance to a water source (a lake or a river) or to various raw material sources was also recorded. Based on a detailed relative chronological system, we were able to establish that the oldest permanent sites were founded in the lowest areas of the basins in the Early Neolithic and the early part of the Middle Neolithic (ca. 6500-5700 BC). During the later MN, these areas were abandoned and new sites emerged at slightly higher altitudes, which were also preserved during the Late Neolithic and the first part of the Chalcolithic. After about 4000 BC, the magoules were abandoned and single-layer sites emerged in new locations in the basins, with new habitats on hilltops also being favoured.

We interpret these relocations over 3000 years of prehistory not only as a cultural change, but also as a response to changing environmental conditions, in particular to fluctuating water levels of a currently desiccated lake as well as to flooding events originating from riverbeds that have also dried out today. This working hypothesis requires further evidence from drillings and geographical investigations.

10 **MAJOR CLIMATIC EVENTS DURING THE MEDITERRANEAN NEOLITHIC DISPERSAL FROM A SHORT-TERM AND LOCAL PERSPECTIVE**  
**Abstract author(s):** Hausmann, Niklas (Römisch Germanisches Zentralmuseum - RGZM; University of York)

**Abstract format:** Oral

This talk will outline how the impact of major climatic events on Neolithic dispersals could be identified and quantified by archaeological research using mollusc shell records.

We aim to use limpet shells from Mesolithic/Neolithic transitional sites of the Mediterranean, to ascertain whether the spread of the Neolithic was accompanied or even constrained by climatic conditions at that time (i.e. 8.2 event, Rapid Climate Change (RCC) Events). Different to long-term climate archives, limpet shells are often found on site and record temperature changes on a seasonal scale, allowing us to measure weather extremes on a resolution that a) would have been noticeable to Neolithic Farmers and b) is essential to agricultural strategies.

The fast maritime expansion of Neolithic farmers across the central and western Mediterranean occurred only after a continental-scale climatic amelioration around 8,000 cal BP (6,000 cal BC) and supposedly after the climate became more predictable. But whether an unpredictable and extreme climate prevented a similarly swift expansion before 8,000 cal BP is not certain, because the local and short-term expressions of this climate are unknown. We hope to provide a better environmental backdrop to this question and quantify extreme short-term events on site should they have occurred.

In addition, Neolithic farmers have been shown to be highly adaptive and often part of a network of sites, strengthening economic as well as social resilience. If major climatic events did cause unpredictable short-term extremes, would they have increased agricultural risks by so much that the spread of farming was constrained?

11 **USING MG/CA RATIOS FROM THE LIMPET PATELLA DEPRESSA PENNANT, 1777 MEASURED BY LASER INDUCED BREAKDOWN SPECTROSCOPY (LIBS) TO RECONSTRUCT PALAEOCLIMATE**

**Abstract author(s):** García-Escárzaga, Asier (Max Planck Institute for the Science of Human History; Universidad del País Vasco - UPV/EHU) - Martínez-Mincheró, Marina (Grupo de Ingeniería Fotónica, Universidad de Cantabria; Instituto de Investigación Sanitaria Valdecilla - IDIVAL) - Cobo, Adolfo (Grupo de Ingeniería Fotónica, Universidad de Cantabria; Instituto de Investigación Sanitaria Valdecilla - IDIVAL; CIBER-BBN, Instituto de Salud Carlos III) - Gutiérrez-Zugasti, Igor (Instituto Internacional de Investigaciones Prehistóricas de Cantabria, Universidad de Cantabria) - Arrizabalaga, Alvaro (Universidad del País Vasco - UPV/EHU) - Roberts, Patrick (Max Planck Institute for the Science of Human History; School of Social Sciences, University of Queensland)

**Abstract format:** Oral

Measurement of the elemental composition of shells is increasingly emerging as an avenue for obtaining high-resolution insights into palaeoclimate and past seasonality. Several studies have shown significant correlations between Mg/Ca ratios measured on shell carbonate and the sea surface temperature (SST) within which this carbonate was precipitated. However, other investigations have reported large variability in this relationship between species. Therefore, further studies including taxa previously not considered are still required in order to validate these new species as suitable climate proxies. Here, we measure Mg/Ca ratios for limpet *Patella depressa* Pennant, 1777 samples live-collected in northern Spain for the first time. The elemental ratio was measured using Laser Induced Breakdown Spectroscopy (LIBS), a technique that significantly decreases the time required for sample preparation and increases the number of shells that can be analysed. In this study, CF-LIBS methods were applied to estimate molar concentrations of chemical elements on biogenic calcium carbonate. The Mg/Ca ratio evolution along the shell growth axis was compared with stable oxygen isotope ( $\delta^{18}O$ ) profiles obtained from these same limpets and the SST at the place where mollusc grew in order to determine if the sequences obtained correctly reflect environmental conditions during the life-span of the mollusc. The results showed a significant correlation between Mg/Ca ratio series and both  $\delta^{18}O$  profiles and SST, highlighting the palaeoenvironmental and archaeological potential of LIBS analyses on this mollusc species that is frequently found in archaeological contexts in the western Europe.

12 **DEMOGRAPHIC FLUCTUATIONS IN THE SOUTHERN LEVANT IN RELATION TO THE 8.2 AND 4.2KA CLIMATE EVENTS**  
**Abstract author(s):** Schmid, Magdalena (Kiel University)

**Abstract format:** Oral

The southern Levant has had multiple cycles of cultural transition and human migration over the last 15.000 years. Causations of mobility are varied and center around opposing hypotheses including the role of rapid climate events and overexploitation of local resources. It has been argued that drought events either had limited impacts on southern Levant communities to they have led to societal collapse.

In this study, a series of quantitative analyses was undertaken (Bayesian, frequency, outlier and aoristic) to correlate climate and archaeological datasets and to provide a robust temporal resolution of the intensity of human occupation on macro and micro scales. Using a new radiocarbon dataset compilation (> 3900 dates from > 580 archaeological sites), this study assess fluctuations in relative population numbers, archaeological sites and 14C-date frequencies. Coupled with aoristic approaches, it establishes for the first time the spatio-temporal distribution of human activities as narrow as 100-year intervals.

This study demonstrates that 14C dates are uniformly distributed among archaeological sites and provide a robust narrative of human population trends. All models show a bottleneck at 8.1 and 4.3/4.0ka. Increased aridity has led to population decrease and the relocation of southern Levantine communities into mesic ecozones, where more stable and abundant resources are available. Increased humidity has led to population increase and relocation into marginal desert zones to allow for diversification of resources as a means of demographic pressure. These findings promise to contribute to the broader archaeological discussion regarding the relocation of human communities as a mitigation strategy for major climate fluctuations.

13 **CLIMATE CHANGE, ADAPTATION AND RESILIENCE IN THE INDUS CIVILIZATION: NEW ARCHAEOBOTANICAL DATA FROM BHANDO QUBO (SINDH, PAKISTAN)**  
**Abstract author(s):** Jiménez Arteaga, Carolina - Madella, Marco - Lancelotti, Carla - Parque Pérez, Óscar (Universitat Pompeu Fabra) - Veesar, Ghualm - Abro, Tasleem - Chandio, Amin (Shah Abdul Latif University)

**Abstract format:** Oral

The Indus Civilization was one of the great early complex societies (c.5.2–3.3 kyrs BP) and the earliest known urban culture of South Asia, spreading across modern Pakistan and India and reaching into Afghanistan during its peak. Archaeological evidence points to continuous adaptation by the Harappan people to climate changes, variable hydrologic regimes and regional ecological differences through diverse farming strategies and a mastery of water-supply management.

While it seems clear that the northwestern sites relied mainly on winter cyclonic rainfall originating in the eastern Mediterranean, southeastern rainfall was almost entirely sourced from the Indian Summer Monsoon. However, little is known about the Indus and Ghaggar-Hakra valleys, located in the transition zone, where both systems are most irregular. This area is of special interest as the western region of the Indo-Gangetic plain saw an unprecedented urban development during the Mature Harappan period (c.4.6–3.9 kys BP). Yet, no systematic studies of plant and animal remains have been done at Indus floodplain sites.

Preliminary archaeobotanical data from Bhandu Qubo, an archaeological site in the alluvial plain of the lower Indus Valley (Sindh, Pakistan), provides an interesting test case for exploring the role of climate in societal transformation. New multi-proxy evidence sheds light into local and regional adaptive strategies to environmental changes in the Indian subcontinent including (but not limited to) the 4.2 kyr aridification event. This new data is deepening our understanding of the rise and fall of Indus cultural traditions.

14 PRELIMINARY THOUGHTS ON SIGNS OF CHANGE IN BRONZE AGE SCOTLAND

**Abstract author(s):** Higginbottom, Gail (El Instituto de Ciencias del Patrimonio - Incipit, CSIC)

**Abstract format:** Oral

Exactly when and why prehistoric Standing stones first appeared remains an enigma (Scarre 2019: 216). Whilst they were culturally significant is already clear, as they came to be used across Europe in their tens of thousands for at least 5000 years (from c. 6000), no-one has discovered the actual reason for the start of these stone monuments in Europe, nor the reasons they stopped being built, nor again why in some areas the construction began anew (Higginbottom et al 2015). Key triggers for such relatively sudden appearances, changes and disappearances in cultures have been linked to a combination of competing cultural/people influxes (Whittle 2018; Olalde et al 2017) or climate change factors (Diers & Fritsch 2019). For Scotland, we know that StS first appeared as the great Circles c. 3000–2900 cal BC (Late Neolithic in Britain; Ashmore 2016; Ritchie 1976), with single StS in association with other monuments and some smaller-stoned circles dating between c. 2900-2600 BC (Bradley 1998; Burl 1993, 2000; Richards 2013b; Ashmore 2016; Ritchie 1976; Schulting et al. 2010; Gibson 2010; Ritchie 1974; Sheridan 2008; Noble and Brophy 2011, 2015). However, despite the fact that some StS monuments were still occasionally reused (Ashmore 2016, Bradley 2000, 2011; Gibson 2010), there are two possible eras of hiatus for their construction, the second one being c. 1800 BC - 1300 BC (Curtis and Wilkin 2012; Higginbottom et al 2015), after which a great number of simple StS monuments were erected across western Scotland (Higginbottom et al. 2015). The intention of this paper is to investigate known climate data and investigate the possible links between these and the start of this Middle Bronze Age megalithic phenomenon. It will also explain why it might be possible that these stones flag a change in the environment of the builders of these monument.

15 THE LITTLE ICE AGE (A.D. 1300-1850) AND ITS IMPACT ON HEALTH AND DIET IN NW SPAIN

**Abstract author(s):** López-Costas, Olalla (EcoPast - Gi-1553, Archaeology Fac. de Xeografía e Historia, Universidade de Santiago de Compostela; Archaeological Research Laboratory, Stockholm University; Laboratorio de Antropología Física, Universidad de Granada) - Mangas-Carrasco, Elvira (EcoPast - Gi-1553, Archaeology Fac. de Xeografía e Historia, Universidade de Santiago de Compostela) - Martínez Cortizas, Antonio (EcoPast - GI-1553, Facultade de Biología, Universidade de Santiago de Compostela)

**Abstract format:** Oral

North-western Spain offers a unique opportunity to explore changes in ancient lifestyles during The Little Ice Age (LIA, AD 1300-1850) due to the availability of detailed regional environmental reconstructions. Investigations based on peat records (pollen and geochemistry) revealed that the climate during the LIA was characterized by intense cooling (a decrease up to 5°C in comparison with maxima in the Medieval warm period), abrupt changes in rainfall, and higher frequency of storms. These changes are also common to other regions of the Iberian Peninsula, but our studies show that Galicia may have had a delay of 100-years in reaching the characteristic cool temperatures of the LIA. In order to understand the impact of these conditions on the human populations, we studied six skeletal collections for paleopathology and dietary changes (using stable isotope analyses in bone collagen). The three coastal collections displayed an increase on marine resources and C4 plants (millet and maize later), when compared with previous centuries. The change in diet fits well with the climate evolution and has been interpreted as a possible strategy to bioproductivity deterioration, as it was also observed in the Roman/post-Roman transition. We also detected elevated rates of porotic lesions such as cribra orbitalia (78%) and femoralis (70%) that could be linked to both diet change and climate deterioration. Infectious diseases such as tuberculosis, related to climate (i.e. fogs) and diet, were also present in the studied collections. Our investigation suggests that it is possible to detect the effects of abrupt climate changes on past human populations. Considering paleoenvironment in paleopathology is clearly an advantage, but we believe that future knowledge depends on including in the “formulae” also more detailed environmental reconstructions.

16 ANALYZING ADULT SURVIVORSHIP FROM CHILDHOOD STRESS DURING THE LITTLE ICE AGE IN THE NORTH AMERICAN GREAT PLAINS

**Abstract author(s):** MinskyRowland, Jocelyn (Smithsonian Instiution; Howard Community College)

**Abstract format:** Oral

Extreme climatic events can affect human populations, culturally, and physiologically. The Little Ice Age (LIA) on the North American Great Plains caused temperature changes and droughts, influencing the availability of resources (1550-1850 CE). The Arikara Native Americans of South Dakota (1600-1832 CE) exhibit several childhood stress markers, including cribra orbitalia/porotic hyperosto-

sis, short stature and linear enamel hypoplasias (LEH). One-hundred and ninety-three adult individuals, with and without LEH, were analyzed for survivorship differences. Survivorship was estimated using Kaplan-Meier estimates with log-rank tests in SPSS version 27 and was analyzed in a two-step process. First survivorship of individuals with and without LEH was compared between the sites. These results were not statistically significant. However, the associated survivorship curves indicate that, among individuals with LEH, those at Mobridge, died earlier in life compared to those at the other sites. Next, survivorship differences, within each site, between individuals with and without LEH, was estimated. These results were only statistically significant for the Mobridge site. The individuals with LEH, at this site, died earlier in life compared to individuals without LEH at Mobridge. Temporally, this is the earliest site, and is not known to have had contact with Euro-American explorers. While Euro-American contact has been shown to influence physiological stress in other contexts, this project reinforces the notion that multiple causes must be considered when evaluating stress in past populations and the variable effects of childhood stress markers on later adult health and survivorship. Furthermore, these results demonstrate the significance in evaluating survivorship within sites, as well as comparing survivorship over time between culturally related sites. Future research will consider survivorship, during the LIA, relative to cribra orbitalia/porotic hyperostosis and in the context of multiple stress markers.

463 WHAT REALLY WAS A CASTLE?: WIDENING THE HORIZONS OF INTERDISCIPLINARY INTERPRETATION

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Swallow, Rachel (University of Liverpool; University of Chester) - Rzepiela, Michał (Department of Medieval Latin of the Institute of Polish Language, the Polish Academy of Sciences, Kraków)

**Format:** Regular session

Past scholars have discussed the unresolved contemporary definition of ‘castle’, generally resorting to the ill-defined ‘private fortified residence of a lord’ for a variety of elite residences, fortified buildings and associated landscapes - including earthwork, timber and masonry fortifications, palaces, manor houses, crenellated church towers and hunting lodges.

Contemporary archaeological research across Europe, however, is now widening the research horizons of current academic disciplines, to include not only Archaeology, but also History; Medieval Literature; Linguistics; Landscape History and Archaeology; Architecture; Digital Humanities. This innovative research approach opens up new debate on what really was a castle? Through emerging research on medieval fortifications, new interpretations will be proposed for the contemporary meaning(s) of scribed words such as castrum, castellum, and domus defensibilis, all commonly translated by later international generations as simply ‘castle.’

Exploring the interplay between archaeological theory and the archaeological sciences, as well as examining the ebb and flow of various theoretical currents and analytical approaches, our session provides the opportunity to come to a better understanding of our shared human past. To revive debate and shed light on this particular problem, we welcome paper proposals of archaeological research aiming to widen the horizons of past castle interpretation in a new, multi-disciplinary and cross-period way.

ABSTRACTS:

1 THE TERMINOLOGY, DISTRIBUTION AND FORM OF FORTIFIED ELITE RESIDENCES IN MEDIEVAL IRELAND, MAN AND ATLANTIC SCOTLAND

**Abstract author(s):** Ó Riagáin, Russell (Independent Scholar)

**Abstract format:** Oral

The presence of castles in Ireland before its incorporation into the Angevin Empire has been a matter of some debate due to the use of several Latin loanwords in Old and Middle Irish relating to enclosed settlements. This paper will apply a transdisciplinary approach, using philological, textual, toponymic, archaeological and architectural evidence together to make a contribution to this debate. The paper will open by treating the use of loanwords in Irish sources in their palaeographical, codicological, and political context. It will also explore the epistemological and ontological systems, and the general intellectual and intertextual context of these texts and their authors. This will shed important light on the motivations of the scribes using these words, seeing as no act of textual production is passive, helping to unpack and unpick their use of terminology. Rather than focus solely on twelfth-century Ireland, the paper will outline the sum evidence for castle-building in areas where Middle Irish/Gaelic was a spoken language, either as the principal language or spoken along with Old Norse, Middle Scots or Middle English, proposing several distinct forms of region-specific castle, which will then be used to explore the examples in Ireland, and how these forms may have influenced the emergence of more widespread castle use outside of core areas of the English colony in Ireland in the later medieval period. This will provide an important corrective to the standard narrative of transculturation in high and late medieval Ireland, by bringing a much wider set of potential interaction and cultural reference into the analysis, and its results will be applicable to encastellation in areas occupied by other speech communities.

2 **CASTLES IN THE RURAL LANDSCAPE: A SEMANTIC PROBLEM IN EUROPEAN ARCHAEOLOGICAL RESEARCHES**

**Abstract author(s):** Bernardi, Martina (Dipartimento di Studi Umanistici, Università degli Studi di Roma Tre)

**Abstract format:** Oral

The castle seems usually to indicate a building located in the rural landscape and dated back to the medieval ages. Indeed, the word castrum summarizes a multiplicity of meanings from the Roman period until today: a military encampment, a fortification located to control the borders the territory around (by sea and by land), a fortified village where peasants live inside, an aristocratic residence, up to the Bavarian medieval fake residence of Ludwig II, which is called castle but is not a castle.

Why Latin sources used just one or two words (castrum or castellum) to define several (and different) settlement realities? This represents a real problem, a semantic trouble in which the researchers have to take into account in their studies.

The purpose of this paper is to concentrate the attention on the different typologies of castles born in the European context, especially in Italy, where the phenomenon of castra can be generally described as a concentration of the rural population inside fortified high-altitude fenced sites, starting between X-XI century AD; but also in this context not all that castles are the same for the different chronology, function, and history.

3 **CLASSICAL WITH A TWIST?: RE-EXAMINING THE ANGLO-NORMAN USE OF THE WORDS CASTRUM AND CASTELLUM FOR ‘CASTLE’ IN ENGLAND**

**Abstract author(s):** Swallow, Rachel (University of Liverpool; University of Chester)

**Abstract format:** Oral

Taking a multi-disciplinary approach to research, this paper (re-)interprets the Anglo-Normans’ documentary use of the words castrum and castellum, both of which are generally—and, it is argued here, over-simply—translated today as ‘castle’. This fresh examination of the originally intended nuance(s) of both terms (re-)considers the language, architecture, archaeology, history—and particularly the multi-period landscapes and their monuments—of a number of English castles and their documentary mentions from the end of the eleventh century. Early conclusions point to a new interpretation, that the late-eleventh-century Anglo-Normans deliberately used either and/or both terms for ‘castle’ in their documents, because different meanings were in fact intended: castellum was communicated to signify the site of a new-build Anglo-Norman castle, and the Anglo-Norman use of castrum—notably a Classical Latin/Roman word originally—intentionally referred to the likely extant walls/delineation of a pre-existing Roman fort as the foundations and wider enclosed area as the basis for a new Anglo-Norman fortification.

4 **JUST AROUND THE RIVERBEND. THE MEDIEVAL FORTRESSES OF THE RIVER SEGRE (11TH CENTURY)**

**Abstract author(s):** Closa Ribera, Ariadna (Universitat Autònoma de Barcelona)

**Abstract format:** Oral

Traditional historiography has considered the castles situated along the river Segre, in its middle section (northeast of the Iberian Peninsula), as “husun”, fortresses from Al-Andalus, built in the context of a castle building programme promoted either by the State or by the muladi family of Banû Qasí, former Christians, throughout the 9th and 10th centuries. These castles were assumed to be part of the defence system of Al-Andalus set in front of the territories of the Christian counties. Nonetheless, the concept of “frontier” has been revised as a moving and dynamic space, where the Catalan counties and the Caliphate of Cordova were able to impose their authority, although in an unstable way. So, these castles were occupied and transformed after the feudal conquest of this area by the counts of Barcelona and Urgell. In the feudal written records, they appear as “castri” and some of them were linked to settlements and means of production, such as mills or irrigated systems, that evolved to permanent settlements. Most of them have endured until the present day.

Without setting aside the military role they played in the frontier, these fortifications developed into a network of castles with no jurisdictional gaps between them created by feudal lords. Castles served as centres of management and control of the population, which transformed the rural landscape. Through the archaeological and historical study of these buildings and their construction materials, as well as the study of their landscapes and their productive spaces, we aim to define their chronology, military function in the frontier, and their role in the colonisation process and control of the land’s population after the feudal conquest.

5 **KEEPING UP APPEARANCES. THE USE OF ARCHAIC ARCHITECTURAL FEATURES IN CASTLES IN THE LOW COUNTRIES (15TH AND 16TH CENTURY)**

**Abstract author(s):** Eekelen, Bart (Utrecht University; Museum Het Markiezenhof)

**Abstract format:** Oral

Over the course of the fifteenth and sixteenth century, the vast majority of nobility’s castles in the Low Countries was not practically defensible anymore against the increased power of artillery. Qualities of defence were often interchanged for a higher degree of comfort and a more representative appearance. Still, these rural dwellings often kept their archaic castellated appearance. Why keeping up appearances?

I will argue that the concept of a castle was inextricably bound to the concept of the past as a justification of the present. The castellated appearance was a visible and tangible reference to the descendance and legitimate rulership of the local lord. So the castle was used to legitimize rulership.

Which architectural features made these castles? For this presentation, I will focus on castles and rural houses of the high nobility in the Low Countries, roughly between 1450 and 1550. By identifying architectural modernizations, we will start recognizing the archaic elements. I will show how some castles/rural dwellings were turned into more representative, modern courts that lost their defensive qualities and at the same time kept characteristic elements of a ‘castle’. I will also relate them to the 1536 definition of the ‘ridderhofstede’ (knight’s house) issued by emperor Charles V. Thereby I will briefly consider contemporary terminology.

6 **THE FORTIFIED LANDSCAPE OF EARLY MEDIEVAL CENTRAL PORTUGAL: CASTLES ON THE HORIZON?**

**Abstract author(s):** Vilarinho, Gil (The University of Edinburgh)

**Abstract format:** Oral

Castles are one of the most conspicuous features of the medieval landscape. The origins of these fortifications have been the subject of ample debate and though some basic features are common across Europe, other aspects are prone to different levels of regionalisms. The administrative and military organization undertaken by Alfonso III of Asturias (r. 866-910) is often considered the first step towards the incastellamento that occurred across the NW Iberian peninsula in the tenth century. The territory was organized in civitates, militar and administrative regions with a network of defensive structures spread across the landscape. Though these structures are mentioned in the literary sources with different nomenclature, such as civitate, castro, castello, penna and others, up until recently the studies of the incastellamento have considered all these fortified structures as castles. But what exactly was a castle in this period? Drawing on evidence from literary sources, archaeological record, aerial surveys and LiDAR data, this study seeks to offer a perspective from central-north Portugal and discuss the architecture, topography and function of the medieval fortifications in the 10th and 11th centuries, using the frontier coastal region between the cities of Coimbra and Porto as a particular case study area. The results presented here allow to widen our horizons on early medieval fortifications and help to build a better understanding of this particular military landscape.

7 **REWRITING THE HISTORY OF THE CASTLES IN THE SOUTH OF THE NORTHERN BORDER OF THE IBERIAN PENINSULA. RIOJAN FORT-TOWERS**

**Abstract author(s):** Espinosa, Isaac (Universidad Autónoma de Madrid & Instituto de Estudios Riojanos)

**Abstract format:** Oral

For hundreds of years, the wars between the Christians and Muslims first, and between the Christian kingdoms later, encouraged the construction of defensive architectures in the valley of the Ebro River and its tributaries, which was known as the Northern Frontier. For this reason, the current Autonomous Community of La Rioja has the highest number of castles per inhabitant in the country, although, unfortunately, many of them are in a dilapidated state.

The objective of this proposal is to analyze the different types of castles that exists in the area, their current state and the restorations that have been carried out in some of them, paying special attention to the Fort-Towers, the most common type in La Rioja, but very unusual in the rest of the country. The actions that have been carried out and the new materials and techniques with which they have been counted will be discussed in order to better understand the history of these castles, demystify and analysing the idiosyncrasy of their construction, value the efforts to rehabilitate them and disseminate to the entire population the new story they offer us. The Fort-Towers represented a change in the mental paradigm of people from the 14th to the 16th centuries, going from a purely defensive mentality for defensive architectures, to a structure that seeks social, economic, administrative, judicial, military, and legislative control and mental of the people that the Lord controls. As there are no monographic studies in this regard in La Rioja and the existing general studies being outdated, an in-depth study and a new point of view in regional castellological studies is necessary.

8 **TRYPOL ON DNEEPER: CASTLE, PALACE, FORTIFIED PALACE, FORTRESS, TOWN: AND WHAT IT REALLY WAS**

**Abstract author(s):** Videiko, Mariia - Videiko, Mykhailo (Kyiv Borys Grinchenko University)

**Abstract format:** Oral

Known from as a city from XIth century, from 1501 this place with area around became property of Fedor Detkovich. For more than a hundred years, Trypol and the castle in it became the residence of family. In 1551 this family became so rich that they built a real masonry castle in the city. The foundations of the castle, erected on the top of the hill, were built of stone, and the upper part of the brick. The castle had towers, one of them was crowned with a dome. Massonry fortification was complemented by an earthen rampart and ditch. The castle was armed with artillery. In documents and narratives described Trepol-Trypillia were used different terms for this fortified place: castle, fortress, palace, fortified palace, town. Using of terms depended on situation and time. In the 16th and 17th centuries, the words “castle” and “town” was used in military relations. In the descriptions travelers used terms a “palace” or a “fortified palace”. The ruins were later perceived as a “fortress”. Archaeological research allows us to combine these quite diverse concepts that actually apply to the same object. Together with the documents, they demonstrate the variety of functions he performed depending on the circumstances and context. Archaeological finds from the central part of the city testify to the wealth of its inhabitants. Trypol-Trypillia was combination of two structures: the medieval castle and the medieval city, both with one owner.

9

The defense functions were of special importance due to their location in the border areas. This is also an interesting example of the existence of a typical European model of a castle so far in the East.

9

## RELATIONSHIP BETWEEN CASTLE AND TOWN IN MEDIEVAL POLAND IN THE LIGHT OF LINGUISTIC EXAMINATION

**Abstract author(s):** Rzepiela, Michal (The Institute of Polish Language, The Polish Academy of Sciences)

**Abstract format:** Oral

A generally adopted perspective when examining the relationship between castle and town in the Middle Ages, is that of the modern expert, who tends to provide a balanced and interdisciplinary interpretation, as far as possible. However, it is only through linguistic examination, and particularly one based on the electronic corpus of Medieval Latin data available, that truly reveals the viewpoint of contemporaries writing about the relationship between their castles and towns. This paper examines such testimonies, focusing on the utterances concerning interaction between town and castle as they are encountered in the corpus of Polish Medieval Latin eFontes. A special attention is given to the distribution and collocational force of the term castrum as well as its more or less synonymic equivalents, such as castellum, arx and fortalitium. The research points to fresh interpretations for the definitions and delimitations of the functions of both castle and town in the medieval social sphere.

10

## “CASTLES” OF THE CENTRAL SICILY

**Abstract author(s):** Patti, Daniela (University of Enna)

**Abstract format:** Oral

The landscape of central Sicily is marked by the presence of several fortified elite residences, but also hilltop fortifications defined generically “castles”.

However, in the publications, with some exceptions, have not been investigated by means of the multidisciplinary research including Landscape History and Archaeology, Archaeology of Architecture, Linguistics, Antropology.

The same word “castle”is used continuously to indicate generically the castles in Medieval age without regards to the different architectonic features, functions, roles, and social cultural processes in the Byzantine, Norman Age and later.

The castles in this area often built or powered in the Norman age, today often appears in establishing assumed by the Swabian age; even if, they are involved in restorations, or damaged, or almost completely destroyed, still characterize the rural and urban landscape of the Island, often in closely topographic proximity with fortified cathedral churches.

The research documents a variety of “castles”, despite the several issues in common, often linked to the rock settlement, characterized by use long time with different functions suggesting that it is a cross-cultural phenomenon.

Only interdisciplinary approach will be allowed to have a detailed and complete analysis of the different phases of the fortified architecture in the central Sicily, also in order to understand the dynamic settlement over the long term and the connected cross- cultural behavioral processes.

A interdisciplinary research, including by means of digital humanities (also important for exploitation and dissemination) it’s necessary for examining large-scale archeological and anthropological questions regarding the “castlescapes” and the unexplored issues about cross-cultural developments of central Sicily within the Mediterranean area.

## „...IN CIVITATEM, QUE BUDEC...” WHAT REALLY WAS THE EARLY MEDIEVAL STRONGHOLD OF BUDEČ?

**Abstract author(s):** Tomanova, Pavla (Institute of Archaeology of the Czech Academy of Sciences, Prague)

**Abstract format:** Oral

The Budeč Stronghold is an abandoned early medieval fortified settlement located in central Bohemia (Czech Republic). It represents a site that would be traditionally labelled as an early medieval “castle”. In the contemporary written evidence of 10th century, Budeč was described with the term „civitas“. Past intensive and systematic archaeological research put together an image of the Budeč Stronghold as one of the most significant regional centres in Bohemia, and an administrative support point of the royal Přemyslid family in the times of emergence of the early medieval Czech state. In this traditional approach, the administrative and political aspects were usually accented.

The proposed paper however aims to offer a different approach to the investigation of the Budeč Stronghold. Recently, a study has been conducted that has focused primarily on the testimony of church architecture and on spatial analyses of the site. The study has combined methods of traditional and digital archaeology, together with history of architecture. Results of the study have put together an image of Budeč as not only an administrative-political centre, but primarily as a missionary centre and support point for Christianisation of the early medieval Přemyslid Bohemia. Moreover, some finds and features at Budeč indicate the everyday reality of the Christianisation process, including cultural syncretism and even violence. To sum up, the proposed paper turns the perspective from a general image of early medieval “castle” to the more specific image of Budeč as a significant (not only) political, but also (and especially) ecclesiastical centre of early medieval Bohemia.

## CONCEALED DRAWBRIDGE IN THE FORBIDDEN CASTLE OF VIRTSU. SNEAKING AROUND THE LACKING LICENCE TO CRENELLATE?

**Abstract author(s):** Kadakas, Villu (Tallinn University)

**Abstract format:** Oral

The fieldwork of 2018 in the ruins of the gatehouse of Virtsu castle (Estonia) revealed a puzzling built element. It appeared that in its final building stage its drawbridge was not located in front of the gatehouse, above the moat, but inside the gatehouse, above a trap pit. This very rare solution among the castles of Europe could be ignored as a random caprice of the owner. However, the written history offers events, which enable to interpret it as a calculated choice. According to written sources, during the Feud of Saare-Lääne (1532–1536), the owner of the castle was on the losing side. Eventually, the winning landlord returned him the land estate with the castle site, but only after it had been demolished, ‘razed to the ground’, and a ban was imposed to build it up again.

There was no legal act to regulate the licence to fortify in medieval Livonia, but the respective chapters of Sachsenspiegel were probably known. The expression ‘razed to the ground’ was obviously an exaggeration as the ruin still stands 1½ storeys high. Combining the material and written evidence, it can be assumed, that Virtsu castle was only stripped of its obvious defensive elements. However, the owner did not overtly cross the ban, but probably tried to compensate the effect by circumventing it in a formal way, by concealing one of the defensive capacities inside the building.

Deception and concealment play an important part in warfare. In case of castles, there has been a lot of discussion of apparently defensive elements with limited or even decorative capacities. This rare case offers an opportunity to discuss the possibilities to identify and interpret the evidence about the opposite – concealment of functional defensive capacities, not so much to deceive the attacking army but rather to fool the landlord.

## SEARCHING FOR THE DUTCH CASTLE LANDSCAPE

**Abstract author(s):** Jong-Lambregts, Nancy (Tilburg University; municipal archaeologist gemeente Alkmaar) - van den Oever, Ferry (Geophysicist Saricon BV)

**Abstract format:** Oral

Castles are part of an extensive infrastructure consisting of outer wards, artisanal buildings, defensive structures, roads, ports and farmsteads: The Castle Landscape. In England it is a common research practice to involve the landscape during castle research, but in the Netherlands the focus used to be on the main castle and not its landscape.

To understand the castles position a holistic, interdisciplinary approach should be used using historical sources, archaeology, remote sensing and using a combination of different geophysical techniques. In the Netherlands this is a new innovative way of doing castle research and is now part of a PhD study.

The research area is the province of North-Holland (Netherlands) and is an important part of the 13th century county ship of Holland. During that era a lot of castles were built as part of a defensive ring of fortresses to suppress the West-Frisians.

The presented case is the spin-off a PhD research and includes a 13th century castle, the Middelburg (Alkmaar), the smallest fortress within the defensive structure. This archaeological cold case from 1942 is reinvestigated using multiple geophysical techniques, renewed extensive historical-archaeological research (including WW2-aerial photography) on a larger scale and the interdisciplinary interpretation of the data. Results showed that the castle was at least three times bigger and had a different function. It wasn’t just a fortress, it was a medieval distribution center, complete with harbor and other functions and not just a military stronghold.

This PhD researches other similar 13th castles in this area using the same interdisciplinary large scale approach to prove that the meaning of these castles needs to be redefined. Applying this approach on Dutch castle research in general will lead to better understanding of the medieval castle and will make it possible to compare with similar castles in international context.

## SOIL AND SEDIMENT MICROMORPHOLOGY IN ARCHAEOLOGY

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Devos, Yannick (Maritime Cultures Research Institute - MARI, Vrije Universiteit Brussel) - Krupski, Mateusz (Archeolodzy.org Foundation; Institute of Soil Science and Environmental Protection, Wrocław University of Environmental and Life Sciences) - Nicosia, Cristiano (Dipartimento dei beni Culturali, Università di Padova)

**Format:** Discussion session

Over the last decades soil and sediment micromorphology has become an important technique to study diverse archaeological problems. Whereas it initially mostly dealt with stratigraphical issues and palaeoenvironmental reconstructions, the scope has definitely widened. This resulted in a steady growth of publications (see for instance Stoops, 2014). Together with this growth we also witness a discipline that reaches its maturity with a series of important reference works.

Although these developments are encouraging, Goldberg and Aldeias (2016) rightly point out that the technique is still underutilized in archaeological research. One of the main points they make is that many archaeologists are still unfamiliar with the discipline and its potential and limitations.

The aim of our session is therefore to present some clear (recent) examples of how soil and sediment micromorphology can be utilised in the archaeological framework. We welcome contributions that highlight the potential of soil and sediment micromorphology to address specific archaeological questions from the interpretation of archaeological structures and stratigraphy to the reconstruction of past environments and the human-environment relations.

ABSTRACTS:

1 MICROMORPHOLOGICAL WAYS

**Abstract author(s):** Goldberg, Paul (University of Tübingen)

**Abstract format:** Oral

A long, long time ago my archaeology professor at the University of Michigan, Henry T. Wright, commented to me, wouldn't it be marvellous to be able to examine in cross section living floors and surfaces such as those at the Upper Palaeolithic site of Pincevent in France? I was a doctoral student in geology so didn't immediately get it. At the time, however, I was a teaching assistant for the sedimentology course and straightaway thought of using thin sections/petrography to tackle this query. I immediately asked the sedimentology professor if there were such a book on the petrography of unconsolidated sediments and soils. He suggested, Brewer's Fabric and Mineral Analysis of Soils. I checked it out of the library and tried to read it over the weekend. I got lost in the terminology and gave up, but I was convinced that there was something of value in studying archaeological deposits (sensu lato) with thin sections. That was over 50 years ago, and the study of archaeological deposits in thin section (whether by 'petrography' or by 'micromorphology') has come a long way in investigating floors and other features, as well as soils and sediments from prehistoric periods to modern ones. In this presentation I will attempt to sketch the development of micromorphology since those days and talk about its future evolution using a few examples of natural soils and sediments from prehistoric and archaeological sites.

2 THE LARGEST SWISS CITY ON A SMALL SCALE: A DECADE OF MICROMORPHOLOGICAL INVESTIGATIONS IN THE OLD TOWN OF ZURICH

**Abstract author(s):** Brönnimann, David (Integrative Prehistory and Archeological Science - IPAS, University of Basel) - Ohnsorg, Petra (ProSpect GmbH; Archaeological Department of the City of Zurich) - Rumo, Andrea - Wyss, Stephan (Archaeological Department of the City of Zurich)

**Abstract format:** Oral

Over the past 12 years, micromorphological analyses have been performed on more than 100 block samples from several archaeological excavations. This large dataset has provided unique insights into the eventful history of Zurich:

1. Reconstruction of the landscape history and lake level changes of Lake Zurich from the Iron Age to the Middle Ages on the basis of fluvial and limnic deposits.
2. Identification of Neolithic, Bronze Age and Iron Age agricultural soils and thus new insights into the use and development of the (cultural) landscape in prehistoric times.
3. Fine-stratigraphic investigations of various archaeological structures such as a Roman water channel, an early medieval glass workshop or laminated medieval house floors.
4. Reconstruction of natural and anthropogenic layer formation processes and, based on this, of different phases.

These multi-faceted results were only possible thanks to the close and continuous cooperation between the Archaeological Department of the City of Zurich and the Geoarchaeology Research Group at IPAS (Integrative Prehistory and Archaeological Science) at the University of Basel. In retrospect, it is apparent that the following points were crucial for this successful collaboration:

1. Fieldwork: the micromorphological research starts on the archaeological excavation. Geoarchaeological fieldwork helps to develop the right research questions and a stringent sampling strategy from the beginning.
2. Trust: honest evaluation of the potential and informative value of micromorphological samples creates a relationship of trust.
3. Rapid results: long time span between sampling and first micromorphological results can be a problem in some situations. Compromise and pragmatism may be required in these instances.
4. Staff continuity: especially in urban areas, where numerous but mostly small excavations take place.

3 BUILDING AND CRAFTING DURING EARLY MIDDLE AGES: MICROMORPHOLOGICAL INVESTIGATIONS INTO OVEN, KILN, AND FURNACE (FRANCE, 6TH – 11TH C.)

**Abstract author(s):** Borderie, Quentin (CNRS UMR 7041 ArScAn) - Bourdelle, Anthony (Univ. Orléans) - Sordoillet, Dominique (Inrap - CNRS UMR6249 Chrono-environnement Besançon)

**Abstract format:** Oral

In France, early medieval fire-related buildings often include excavated pits and fire chambers, such as in oven, kiln, and furnace. If the most of the building is scarcely preserved due to the erosion, the excavated parts are very regularly found in archaeological sites. The fillings of those pits are complex, both in the fire chamber as in the working area. In the latter, the stratification is made of a large number of thin or thick layers which can be hardly excavated one by one with a trowell due to their small size. They contain ashes, phytoliths, charcoals, and other very diversified fragments of artefact depending on the type of the building. In cooking oven, burnt bread or seeds and gramineae phytoliths can be encountered, while in metal working ones burnt iron oxydes and slaggs are numerous. In every type of working pits, strata can contain a large amount of burnt aggregates of silty clay, soils, and thin floor preparation layers. Into the fire chamber, layers can be produced by the building and the re-building of the hearth, the roof, or the flue which can have collapsed into the chamber. They also can contain ashy layers with charcoals. The micromorphological investigation of several buildings allows to better understand the processes of accumulation of the thin layers into the working area, where trampled floors can be built in relation with the refurbishing of the fire chamber. In few cases, the probable use of excrements as fuel can be assumed. Micromorphology gives clue data about the manufacturing of earth based building materials but also concerning the processes of heating, cleaning and rebuilding the fire chamber. Finally, it's the crafting activities, the social perception of waste, and the managment of space that are highlighted.

4 UNDERSTANDING COMPLEX URBAN STRATIGRAPHIES IN NORTHWESTERN EUROPE THROUGH SOIL AND SEDIMENT MICROMORPHOLOGY

**Abstract author(s):** Wouters, Barbora (Vrije Universiteit Brussel)

**Abstract format:** Oral

Micromorphology, the microscopic study of soils and sediments, is a highly suited method for the identification of natural as well as anthropogenic processes on archaeological sites. It is ideal for the detailed study of human activities, the environmental context and site taphonomy, and especially so in the framework of complex stratigraphies, such as those typically encountered in urban contexts. Two specific phenomena, dark earths on the one hand, and microlaminated deposits on the other, that often occur in urban excavations, can arguably be understood solely through the application of high-definition methods such as micromorphology. This contribution explores the ways in which soil and sediment micromorphology has contributed to our understanding of several urban sites in Northwestern Europe from Late Antiquity to the High Middle Ages. The focus will lie on a number of common research questions concerning the character and development of towns based on their stratigraphical information, such as their foundations and earliest development, the character of dark earths and thinly stratified floor deposits, the evolution of activities through time, as well as on questions about indoor versus open spaces such as (street) markets, and finally, marked depositional events and post-depositional alterations. This contribution will zoom in on the types and extent of archaeological interpretations that can be procured using this method. It will also mention where it is complementary with other techniques in order to attain the best possible resolution of interpretations.

Case studies from the Low Countries and Scandinavia illustrate how this approach has the potential to bypass a generalising discourse of (early) medieval towns and lead to sometimes unexpected results. Sites such as Ribe (Denmark), Ieper and Lier (Belgium) and others will be presented in order to demonstrate how the above-mentioned questions can be answered for urban contexts in a temperate climate.

5 MICROMORPHOLOGY OF PREHISTORIC DITCH INFILLS. TOWARDS THE IDENTIFICATION OF FORMATION PROCESSES AND LAND-USE AT ARCHAEOLOGICAL SITES

**Abstract author(s):** Krupski, Mateusz (Archeolodzy.org Foundation; Institute of Soil Science and Environmental Protection, Wrocław University of Environmental and Life Sciences)

**Abstract format:** Oral

Features cut into the soil, such as pits and ditches constitute a major part of the archaeological heritage worldwide. In the absence of occupational layers and free-standing structures (embankments, mounds), often poorly preserved in areas with a history of intensive, modern-era agriculture, the infills of these features represent the only stratigraphic sequences available for study. Micromorphology plays a prominent role in the identification of formation processes of this record.

Enclosures are spectacular relicts of past societies. Their significance in prehistoric cultural landscapes is a long-debated subject – they have been described as fortified settlements, places of social/ritual and economic importance (e.g. animal pens). The use of enclosures might have changed in time, nevertheless, the conducted activities are presumably recorded in the stratigraphy of archaeological features.

This issue was explored in detail during research at two double- and triple-ditched enclosures, with different layouts and initial interpretations – Mikulin (Neolithic) and Pietrowice Wielkie (early Bronze Age), both located in the loess-zone in S Poland. The macro-

scopically identified layers of the ditch infills were sampled and studied also in thin sections. This allowed to recognize certain sets of soil features (microfacies) and link them to depositional processes (natural and anthropogenic) and postdepositional alterations. The infills consist largely of colluvium translocated from the prehistoric surface, ditch walls and ramparts and bearing diverse signs of anthropogenic enrichment. Direct human action is evidenced by intentional backfilling and single episodes of waste-dumping and fire management. In some cases, postdepositional processes have led to substantial modifications of physico-chemical properties of the layers (e.g. formation of humus horizons).

In sum, different use-patterns of individual ditches were observed. Placed in a relative and absolute chronological timeframe, this showed variations in human activity in certain zones of the enclosures.

## 6 GEOARCHAEOLOGICAL PERSPECTIVES ON EARLY IRON AGE BURIAL MOUND BUILDING IN SLOVENIA

**Abstract author(s):** Prijatelj, Agni (Durham University, Department of Archaeology; University of Ljubljana, Faculty of Arts, Department of Archaeology) - Gruškovnjak, Luka (University of Ljubljana, Faculty of Arts, Department of Archaeology) - Turniški, Rok - Grčman, Helena (University of Ljubljana, The Biotechnical Faculty, Department of Agronomy) - Črešnar, Matija (University of Ljubljana, Faculty of Arts, Department of Archaeology) - Grahek, Lucija (Research Centre of the Slovenian Academy of Sciences and Arts, Institute of Archaeology) - Brezigar, Barbara (Avgusta d.o.o.) - Draksler, Matej (Skupina STIK)

**Abstract format:** Oral

As conspicuous and (occasionally) monumental grave-markers, burial mounds are one of the most recognizable elements of past and present landscapes. Soil/sediment micromorphology and select complementary analyses allow us to examine them as an independent archaeological source with the potential to reveal information on materials, distinct construction techniques and, ultimately, symbolic and ritual meanings embedded within their distinct materiality.

In this paper, we present the preliminary results of geoarchaeological research into four Early Iron Age burial mounds in Slovenia: at Poštela (NE Slovenia), Vače and Trata near Škofja Loka (Central Slovenia), and Podzemelj (SE Slovenia). Here, we address two research questions. First, were all the examined mounds man-made, or did people, in some instances at least, pragmatically take advantage of the local, undulating terrain? Second, what distinct materials, construction techniques and symbolic and ritual meanings can be recognised and/or inferred from the study of their stratigraphy?

The paper is structured into two sections. In the first, we present the four mounds on a macro-scale by comparing and contrasting their diverse geomorphological settings ranging from the Pleistocene alluvial terraces to complex slope systems. We also examine the strengths of micromorphological and other supporting analyses that may help to discern between natural and man-made mounds. In the second part of the paper, we present the preliminary results of micromorphological and bulk analyses of soils from the Poštela mound and highlight a complex interplay of anthropogenic, geogenic and pedogenic processes involved in the formation of the mound’s intricate stratigraphy. To transcend the persisting misconception of burial mounds as a mere mass of dumped earth, we demonstrate their significant potential for revealing information that cannot be garnered through the study of graves, tombs or grave goods assemblages they contain.

## 7 PALEOCLIMATIC RECONSTRUCTIONS BASED ON THE STUDY OF BIG KURGANS OF THE BRONZE AGE IN THE STEPPE AREA OF RUSSIA

**Abstract author(s):** Khokhlova, Olga - Sverchkova, Alena (Institute of Physicochemical and Biological Problems of Soil Science, Russian Academy of Sciences)

**Abstract format:** Oral

Kurgans of considerable sizes often have several structures made one after the other. It allows studying a horizontal chronosequence of paleosols buried under those structures from a center to a periphery of a kurgan. Geoarchaeological studies were conducted in two key areas: in Krasnodar (kurgan Beisuzhek 9) and Stavropol (kurgan Essentuksky 1) regions in the steppe area of Russia.

Kurgan Essentuksky 1 was built in the second quarter of the 4th millennium BC (early stage of the Maykop culture) according to a single plan in a short time (several decades). The kurgan with a height of 5.5-6.0 m and a diameter of over 60 m consisted of four earthen structures. These structures consisted of alternating layers of dark and light materials that were taken from buried soils. This is confirmed by similar changes in the physicochemical properties of paleosols and overlying kurgan structures.

In the Beysuzhek 9 kurgan, three earthen structures of different ages were identified: the first and the second was built at the middle of the 2nd millennium BC (Novotitorovo culture), the third construction – at the beginning of the 2nd millennium BC (Catacomb culture). The height of the kurgan was more than 4 m, the diameter - about 100 m. The material of structures was a soil mass from the middle horizons of the buried soils.

As the material for the different constructions of the kurgans was mainly obtained from local soils, therefore, changes in soil properties affected the properties of the earthen material of the kurgan structures. According to the analysis of the physicochemical properties of both paleosols and the material of structures of two kurgans, an increase in climatic aridization is reconstructed during the time interval of their building. The technical and technological approaches of the kurgans’ construction were also examined using a micromorphological approach.

## 8 A FUMIER DEPOSIT IN A VOLCANIC ISLAND: MICROSTRATIGRAPHY AND MINERALOGICAL DIAGENETIC PATHWAYS AT BELMACO CAVE

**Abstract author(s):** Fernández-Palacios, Enrique (Archaeological Micromorphology and Biomarkers - AMBI - Research Lab, Instituto Universitario de Bio-Orgánica Antonio González, Universidad de La Laguna; Dept. de Geografía e Historia, Facultad de Humanidades, Universidad de La Laguna; Institute for Archaeological Sciences, Eberhard Karls Universität Tübingen) - Mentzer, Susan (Institute for Archaeological Sciences, Eberhard Karls Universität Tübingen) - Mallol, Carolina (Archaeological Micromorphology and Biomarkers - AMBI - Research Lab, Instituto Universitario de Bio-Orgánica Antonio González, Universidad de La Laguna; Dept. de Geografía e Historia, Facultad de Humanidades, Universidad de La Laguna)

**Abstract format:** Oral

Prehistoric burnt animal stabling accumulations in caves and rock-shelters, also known as fumiers, have been widely documented across the Mediterranean region dating from the Neolithic to the Iron Age. The sedimentary features of these stabling deposits reflect regular substrate maintenance through burning. They are characterized by complex, and often thick stratified sequences comprise of alternating thin sedimentary layers of burnt and unburnt animal dung and plant fodder capped with wood ash or dung ash layers. Here, we present results from a high-resolution geoarchaeological study conducted on sediment samples from an approximately 700-to-1100-year old fumier deposit at the aboriginal site of Belmaco Cave (La Palma, Canary Islands). We combined soil micromorphology, Fourier-transform infrared spectroscopy (FTIR), micro-X-ray fluorescence (μ-XRF), and X-ray diffraction (XRD) to understand the site formation processes involved in the Belmaco Cave fumier. We documented recurrent goat/sheep habitation and maintenance activity throughout the sequence represented by interstratified layers of unburned dung, charcoal-rich sediment, and dung ash. Radiocarbon dates available for the sequence allowed us to estimate a minimum of 10 stabling episodes across a period of 200 to 400 years. Our results also revealed a suite of authigenic minerals, some of which have been previously documented in fumier (e.g. sylvite) and others that are not commonly reported (e.g. aragonite). Some of these were possibly formed through diagenetic interaction between the dung-derived components and the geogenic ones (volcanogenic rocks and clay). Our study contributes an example of a relatively recent fumier deposit in a volcanic island setting, corroborating the presence of the characteristic sedimentary features of these kinds of deposits and revealing previously undocumented fumier-related diagenetic alteration.

## 9 SAMPLING FOR MULTIPROXY MICROSTRATIGRAPHIC ANALYSIS IN DOMESTIC ARCHAEOLOGICAL CONTEXTS: THE CASES OF CERRO DE SAN VICENTE AND CUEVA PINTADA

**Abstract author(s):** Tomé, Laura (Archaeological Micromorphology and Biomarker Research Lab, Instituto Universitario de Bio-Orgánica Antonio González, Universidad de La Laguna; Dept. de Geografía e Historia, Facultad de Humanidades, Universidad de La Laguna) - Herrera-Herrera, Antonio (Archaeological Micromorphology and Biomarker Research Lab, Instituto Universitario de Bio-Orgánica Antonio González, Universidad de La Laguna) - Blanco-González, Antonio (Dept. de Prehistoria, Facultad de Geografía e Historia, Universidad de Salamanca) - Onrubia Pintado, Jorge (Dept. de Historia, Facultad de Letras, Universidad de Castilla-La Mancha) - Rodríguez Santana, Carmen Gloria - Sáenz, Iñaki (Museo y Parque Arqueológico Cueva Pintada – Cabildo de Gran Canaria) - Mallol, Carolina (Archaeological Micromorphology and Biomarker Research Lab, Instituto Universitario de Bio-Orgánica Antonio González, Universidad de La Laguna; Dept. de Geografía e Historia, Facultad de Humanidades, Universidad de La Laguna; ICArEHB - Interdisciplinary Center for Archaeology and the Evolution of Human Behaviour, Universidade do Algarve)

**Abstract format:** Oral

Multi-technique microcontextual approaches have been proven to be efficient in archaeological science. For example, joint archaeological soil micromorphology and lipid biomarker analysis have played an important role in reconstructing site formation processes, obtaining paleoenvironmental data and identifying relevant human behavioral patterns. However, currently there is uncertainty in the degree of microstratigraphic correlation between micromorphological and lipid biomarker data due to the sampling method, which consists in collecting an undisturbed block and loose sediment next to it. Here, we present the first tests towards more accurate sampling. We collected two adjacent undisturbed blocks: one for micromorphology and the other to be subsampled for subsequent lipid biomarker analysis. We applied this sampling method at two different archaeological domestic contexts from the sites of Cerro de San Vicente (Early Iron Age) and Cueva Pintada (Canarian Prehistory). The blocks from Cerro de San Vicente were sufficiently compact for handling and transport to the lab, where they were successfully excavated and subsampled. Those from Cueva Pintada were loose, and subsampling for lipid biomarkers was meticulously carried out in situ. In both cases, lipid biomarker subsampling from undisturbed blocks provided the opportunity to identify different visible microfacies while sampling. Future analysis of all the samples will tell if the new sampling method is likely to result in more accurate, microcontextualized data.

IN WHAT WAYS CAN ANT ACTIVITY AID IN CLARIFYING, OR DISGUIISING OF ARCHAEOLOGICAL SEDIMENT FORMATION PROCESSES?

**Abstract author(s):** Lisá, Lenka (Institute of Geology CAS, Prague) - Mohammadi, Sahar (Department of Applied Geoinformatics and Spatial Planning, University of Life Science) - Bajer, Aleš (Department of Geology and Pedology, Faculty of Forestry and Wood Technology, Mendel University in Brno) - Rohovec, Jan (Institute of Geology CAS, Prague) - Hajnalová, Marie - Goláňová, Petra (Masaryk University, Faculty of Philosophy, Department of Archaeology and Museology, Brno) - Fránková, Markéta (Department of Paleocoogy, Institute of Botany, The Czech Academy of Sciences, Brno)

**Abstract format:** Oral

The implementation of the modern methods brought the possibility to detect human influence on the soil via chemistry or via soil microstructure. On the other hand humans are not the only triggers of the soil properties. One of the very active part of the soil microfauna is represented by ants. What is their role in mechanical and chemical impact on archaeological sediments?

The effect of possible ant bioturbation on archaeological soils was studied at the Celtic oppidum Bibracte located in the SE France. Sedimentary archives containing visible ant hills those with only imprints of former hills those with no visible traces of human or ant influence as well as those influenced by human presence were compared. The sections were compared using the multiproxy approach. The methods of ICP from Mehlich III and XRF, TOC, TN, magnetic susceptibility, grain size distribution combined with micro-morphological observations were the main methodological approaches.

Ants are able to influence the soil into a depth through vertical and lateral galleries which are macroscopically difficult to recognize. They produce special type of granular microstructure. Ants pick up soil grains, bite off fragments of soil aggregates and relocate soil particles from deeper soil horizons to the top surface and the soil organic matter together with the microcharcoal is buried deeper increasing the water holding capacity of deep soil. Among the chemical properties an increase in soil organic matter (organic carbon), P, N, K, Na, Ca and Mg which may be miss leaded with the human activity has been reported. Ant-impacted soils are generally lower in clay, higher in sand and silt. Generally, ant action doesn´t have strong impact on artefact relocation but may be disguising when interpreting the archaeological signal only via chemistry or archaeobotanical studies.

ROMAN MITHRAS CULT UNDER THE MICROSCOPE: NEW INSIGHTS INTO RITUALS THROUGH MICROMORPHOLOGY, HISTOTAPHONOMY AND ZOOARCHAEOLOGY

**Abstract author(s):** Lo Russo, Sarah (MARI, Vrije Universiteit Brussel; IPAS - Integrative Prehistory and Archaeological Science, University of Basel) - David, Brönnimann - Deschler-Erb, Sabine (IPAS - Integrative Prehistory and Archaeological Science, University of Basel) - Ebnöther, Christa (University of Bern) - Rentzel, Philippe (IPAS - Integrative Prehistory and Archaeological Science, University of Basel)

**Abstract format:** Oral

Roman Mithraism was a mystery cult known in the whole Roman empire. Mithras was worshiped in small communities and the cult actions to be kept (mostly) secret to outsiders.

Our contribution shows the potential soil micromorphology has to study Roman Mithraism, especially combined with zooarchaeology and histotaphonomy. This study highlights that multiple floor constructions as well as the related deposits and (micro-) artefacts of cultic indoor features are important sources of information - mostly unused in the otherwise broad and interdisciplinary research field.

Thanks to the recent micromorphological investigations in two mithraea (Biesheim F, Kempraten CH) and one cult cave (Zillis CH), it was possible to demonstrate that repeatedly spreading combustion residues and renewing the floor was an important part of the cult practices of Mithraism in the studied areas. The combination of micromorphological, histotaphonomical and zooarchaeological approaches enabled a systematic evaluation of thermal alteration and bioerosion (in particular bacterial attack) on animal bone fragments. This allows an identification and differentiation of various (cult) practices involving animals so far unknown to Roman Mithraism.

Our results suggest that a cult practice consisting of several stages was carried out on all three sites under study – a ritual so far unknown.

MICROMORPHOLOGY- AND XRF-BASED TYPOLOGY OF CERAMICS IN EARLY MEDIEVAL TOWN OF DZHANKENT (KAZAKHSTAN)

**Abstract author(s):** Karpova, Julia - Bronnikova, Maria (Institute of Geography Russian Academy of Sciences) - Amirgalina, Gulmira (Kyzylorda University named after Korkyt Ata, Scientific Center “Archeology and Ethnography”; Tübingen University) - Arzhantseva, Irina (Institute of Ethnology and Anthropology Russian Academy of Science; Institute for Oriental and Classical Studies, Higher School of Economics) - Haerke, Heinrich (Tübingen University; Institute for Oriental and Classical Studies, Higher School of Economics)

**Abstract format:** Oral

Micromorphology and XRF-analysis provide valuable information about ceramic craft technologies, sources of raw materials, their processing, and in some cases allow to suggests local production or possible importation of ceramics.

This paper presents the results of study of ceramic fragments from early medieval settlement Dzhan Kent using micromorphology and XRF-analysis. The site is located in the ancient delta of Syrdarya River in the south-west of Kazakhstan. The objectives of the study included characterization of the composition and morphology of ceramic fragments and local raw clays: bulk chemical composition, thin-section studies of key micromorphological features such as particle size distribution, colour, porosity, homogeneity/ heterogeneity, features indicative of artificially added non-plastic leaning admixtures into the dough, reconstruction of technology and firing conditions.

In total, 4 samples of local raw clays and 15 samples of ceramic fragments were examined assigned to packing, dining, kitchen and household items. Based on their bulk chemical composition and morphological features a morpho-substantive typology was developed. The studied fragments were clearly subdivided by chemical and microelements composition into two groups. Group I includes high-calcium samples supposedly in-site manufactures. These samples were made from high-carbonate «fat» highly plastic clay with a low proportion of coarse silicate fractions. The dough of ceramic fragments is dense, fine-pored, colour is from grey-olive to dark-brown. Some samples contain different types of artificially introduced leaner. Sintering traces of the clay mass indicate high firing temperatures (800-1000 C). Group II incorporates all imported ceramic fragments. Samples of this group are low-calcium, made of low-carbonate meagre clay. The dough of ceramic fragments unevenly coloured, porous with the addition of different types of leaner. Low amorphization degree of clay mass, indicate low firing temperatures (500-900 C). Every group was further subdivided on the basis of firing conditions, colour, the presence of an artificially introduced leaner and its composition.

MICROPEPPER: AN AFFORDABLE 3D PRINTED PORTABLE PETROGRAPHIC MICROSCOPE FOR SCIENCE AND EDUCATION

**Abstract author(s):** Barbieri, Alvise - Aldeias, Vera (Universidade do Algarve)

**Abstract format:** Poster

The infrastructures required for the visualisation of micromorphological samples as well as the microscopes used for teaching and thin section analysis are costly for most institutes and companies working in archaeology, especially in developing countries. Consequently, despite the increase number of case studies and applications, micromorphology remains poorly known and/or understood outside the close network of its specialists (Goldberg and Aldeias 2018 [1]).

To make micromorphology more accessible, we have developed an affordable 3D PrintEd Portable PEtRographic Microscope (MicroPEPPER). MicroPEPPER combines the low magnification of a stereoscope with the specifications of a petrographic microscope (rotating stage and analyser) and it is designed for high education, on-site analyses, museum exhibits, and scientific workshops/ meetings. With MicroPEPPER it is possible to easily connect a smartphone to a x20 objective, allowing for an on-screen magnification of ca. x8 to x32 (depending on the smartphone model). The integration of a smartphone in the design allows for three main advantages. (1) Two users can comfortably look together at the same thin section, making this microscope the perfect tool to be used for teaching, outreach, and workshops. (2) Thanks to the compact and light design (<0.4 Kg), MicroPEPPER can be easily carried to the field to perform real time analyses (Goren 2014 [2]). Lastly, (3) no licensed software is required to take photomicrographs.

The raw materials used in a MicroPEPPER (0.07 L of 1.75 mm PLA filament, x20 objective, light source, cooling fan for smartphone, polarizing filters) cost less than 30 €, making it an affordable solution for institutes and businesses working on a limited budget. In the future we plan to further develop MicroPEPPER, adding more features such as a condenser, custom objectives, and a tailored software to add labels and perform measurements on real-time images.

NEW PERSPECTIVE ON NEOLITHIC RECTANGULAR FEATURES USING SOIL MICROMORPHOLOGY AND ETHNOARCHAEOLOGY. A CASE STUDY FROM STŘELICE U BRNA, CZECH REPUBLIC

**Abstract author(s):** Lisá, Lenka (Institute of Geology CAS, Prague) - Trampota, František (Institute of Archaeology and museology, Masaryk university) - Parma, David (Archaeological Heritage Institute Brno) - Hrnčíř, Václav (Institute of Archaeology of the Czech Academy of Sciences, Prague) - Přichystal, Antonín (Department of Geological Sciences, Faculty of Science, Masaryk University) - Nývltová Fišáková, Miriam (Department of Physiology, Faculty of Medicine, Masaryk University) - Dreslerová, Gabriela (Masaryk Museum in Hodonín)

**Abstract format:** Poster

The function of sunken rectangular features in the Late Neolithic has been a subject of interest in Central Europe for many years. This type of pit is not found very often. One of the latest examples is a square Lengyel feature in the village of Střelice near Brno. A study of the microstratigraphy of fill has made it possible to qualitatively move the debate to a new level. The qualitative assessment of bone micro-fragments is also innovative for the method of micromorphology in the archaeological context. The study also includes an analysis of artefacts in the actual fill of feature 562, especially the deposits of fragments of “other lithic industry”, pottery and parts of an animal’s body. The discovered situation is then interpreted in the context of other known contemporary features of this type. The presence of excrement with digested bone micro-fragments in the lower layer and the absence of a floor treatment, tread horizon or bedding can be interpreted in the context of ethnoarchaeological knowledge in the broader context of

the activities of archaic societies, e.g., as the short-term use of a faecal pit for an omnivorous or carnivorous species (bear) with a subsequent ritual ending.

## THE FUTURE IS NOW: SUSTAINABLE APPROACHES TO POST-PANDEMIC UNDERSTANDING AND MANAGEMENT OF CULTURAL HERITAGE

**Theme:** 3. The new normality of heritage management and museums in post-Covid times

**Organisers:** Hadji, Athena (DIKEMES - College Year in Athens; Independent Social Research Foundation; Hellenic Ministry of Culture) - Serin, Ufuk (Middle East Technical University)

**Format:** Regular session

As we approach the end of the annus horribilis 2020, it is imperative that we widen our horizons both as human beings and scholars. Tangible cultural heritage has been hit extremely hard by the pandemic and its consequences, with most museums and sites around the globe closed intermittently or permanently. Moreover, intangible heritage, in the sense of values, ideas and principles that give coherence to the social and cultural fabric of contemporary societies, has been shaken de profundis. One thing that emerges clearly from the pandemic is that our existing cultural policies and cultural attitudes do not correspond to the 21st century and its realities.

A call for sustainability in heritage and heritage-related practices, made urgent by the visible, tangible and measurable environmental impact on heritage sites has been underway for quite some time. Along these lines, measures were taken in certain circumstances, sometimes of ambivalent purpose (i.e. MOSES project in flood-befallen Venice). Still, a common approach based on a consensus of urgency for all matters pertaining to heritage and its management is still lacking.

The lack of visitors during the pandemic was beneficial for many sites, catastrophic for most major museums and cultural institutions, indicative of a problem that cannot wait any longer to be addressed: whose heritage is it? Whom do we invite to partake in heritage as stakeholders and practitioners thereof? How do we plan to assume responsibility for an Anthropocene-induced trauma that undoubtedly will haunt humanity for years to come?

We invite contributions that relate to heritage, its understanding and management amidst and in the aftermath of the pandemic, as an endeavor to establish impact and evaluate lessons learnt.

### ABSTRACTS:

## 1 (RE)DEFINING HERITAGE: PEOPLE-CENTERED STRATEGIES FOR A MORE SUSTAINABLE HERITAGE FUTURE

**Abstract author(s):** Arauz, Emily (Independent Scholar)

**Abstract format:** Oral

Following the global pandemic of 2020, we are facing new critical issues in 2021 that are unprecedented for our generation and within the field of heritage studies. The research presented in this paper was originally developed and conducted in the wake of the 2015 European “Migration Crisis” to address the concept of migratory heritage. At the heart of this research was the belief that heritage could be defined on a personal level. Responses to the question “What is your heritage?” asked during interviews conducted with persons on the move in 2017 in Berlin and Amsterdam, illustrated that heritage moves, changes, and adapts as people move between cities, across borders, and over seas. These insights ultimately revealed an alternative approach to the top-down heritage processes that focus on heritage defined by national governments, proffering instead a bottom-up approach that conveys transnational, personal, and conceptual forms of heritage.

Applying this methodology to a post-pandemic field of heritage studies, these results can provide a more sustainable model for defining heritage via individuals and their personal experiences. Informed by the people-centered and rights-based approaches put forth by ICCROM and ICOMOS, respectively, and based on an in-depth analysis of participatory structures, this paper proposes a collaborative approach to heritage that acknowledges the role of individuals in heritage processes. Suggesting a way forward, this paper will share plans for a crowdsourced digital archive intended as a dynamic platform of heritage makers that can transgress national borders and establish a collaborative initiative towards defining forms of personal heritage. While the post-pandemic social landscape and implications for the heritage field may not yet be fully apparent in 2021, this research endeavors to provide a sustainable framework for rethinking which, how, and by whom heritage is defined.

## 2 MANIPULATION OF HISTORY AND CREATION OF HERITAGE IN MARDIN: POST-PANDEMIC PROSPECTS

**Abstract author(s):** Karaoglu Köksalan, Ipek (Middle East Technical University; Harvard University Graduate School of Design)

**Abstract format:** Oral

Mardin has been a city of so many cultures, religions, and ethnicities coexisting together since the early periods of the Ottoman Empire. Over the last fifty years, natives and the residents of the area moved out of the city due to political unrest, insufficient government investment, and economic hardship. As the city became more touristic in the last decade, a whole new set of dynamics came into play. Those who have managed to stay in Mardin after all the political unrest, who were mostly low-income Syriac Christians, Kurds, and Syrian immigrants had to then move out of the historic center of Mardin due to gentrification. The city's historic

built environment has been utilized to promote “heritage”. The use of historic urban fabric to promote “heritage” can potentially lead to the invalidation of cultures and histories. With the introduction of tourism, “history” and “heritage” as Lowenthal describes, are converted to transactional instruments, and become tools of neoliberalism. The Covid-19 pandemic continues to have adverse effects on communities and reveal economic, social, and cultural inequalities. In what ways can post-pandemic conditions expose what the manipulation of history and creation of heritage for the sake of tourism and neoliberal values have created, and what its consequences are? In what ways can it open a new chapter in how cultural tourism is managed in Mardin? Our challenge post-pandemic is to manage and regulate the interdependent systems involving the national and local governments, NGOs, the third and private sectors to address cultural, social, and economic injustices faced in sites where diverse communities live.

## A BILATERAL ASSEMBLAGE IN HERITAGE PRACTICES AMIDST THE PANDEMIC: PROMOTION OF MUSEUMS THROUGH ARCHAEOLOGICAL HERITAGE SITE MANAGEMENT

**Abstract author(s):** Kalfa-Atakli, Basak (Cankaya University; Middle East Technical University)

**Abstract format:** Oral

Covid-19 has had repercussions on multiple fields in various and unexpected ways. Undoubtedly, heritage studies, especially museums, have had their share of damage. According to UNESCO, 90% percent of the museums had to temporarily close their doors, and 10% of them are expected to remain closed for good. Though the pandemic may be the first significant global test for humanity in the 21st century, museums transcended the 20th century, the period of wars and pandemics. Owing to their resilience, museums survived these ‘shifts in paradigm’ adapting themselves and their environments to contemporary realities. In the turmoil of outbreaks, some museums were assigned to inform the public on the ongoing disasters, and some were converted into hospitals. Thanks to the developments in technology and in the construction industry, it would be irrational to expect the previous transformations to happen today. In this study, a ‘site-driven survival plan’ is to be offered for the museums displaying archaeological materials, considering archaeological sites and the affiliated museums as ‘assemblages’. Coined by Gilles Deleuze and Félix Guattari in 1980 as an ontological framework, assemblage theory claims that the components of a body are not fixed, and their role and scale in the assemblage are dynamic. As museums have functioned as hospitals in the past, given their spatial opportunities amid pandemics, today archaeological sites should come forward in heritage practices on account of their open-air and intrinsically ‘social-distanced’ qualities. Therefore, by advancing or introducing appropriate interpretation and presentation methods in archaeological sites to attract and inform the visitors and sponsors, the affiliated museums and sites themselves could be promoted. This paper, thus, aims to establish the role of archaeological sites to nourish museums during and after pandemics within the broader perspective of the assemblage theory to develop a management plan concerning the archaeological site-museum relationship.

4

## READY-TO-WEAR: ART MUSEUMS AND COMMERCIAL COLLABORATIONS DURING THE PANDEMIC

**Abstract author(s):** Hadji, Athena (DIKEMES - College Year in Athens; Independent Social Research Foundation)

**Abstract format:** Oral

The production of commodities licenced after art is not a novelty in 2020-2021. Museums, especially art museums, have profited from issuing and/ or licensing products inspired by their collections for a long time: Mona Lisa has been printed on anything from neckties to toilet paper rolls!

However, two commercial collaborations, both appearing in 2020, are of special interest: TATE MODERN with global brand Pulland-Bear (Inditex company) and MOMA with streetwear brand Vans, both targeting a group of young customers, not the usual “museum crowd”. A side case is the collaboration between banana producer and exporter, Chiquita, and major museums for their “art stickers” collection.

Through a visual exploration of styles as well as a discussion of the economics behind the aforementioned deals, the contribution explores issues of (sustainable?) survival in times of global crisis for major art organizations. Is commercialization a sellout or perhaps the only way out from now on?

5

## STUDY ABROAD FROM HOME: DIGITAL TECHNOLOGY, CULTURAL HERITAGE, AND THE COLLEGE CURRICULUM

**Abstract author(s):** Kontes, Zoe (Kenyon College)

**Abstract format:** Oral

In a liberal arts college setting in the United States, the loss of study abroad opportunities for our students during the pandemic has been a devastating blow. To not be able to see, hear, feel, and experience in person the cultural heritage and archaeological history of another country is a true detriment to students’ education, but also to our mutual human understanding. However, the adoption and adaptation of digital technologies allowing for virtual travel and learning about cultural heritage—for instance via on-site lectures given by faculty at study abroad programs or foreign archaeological schools, remote workshops on preservation and conservation, virtual museum tours, podcasts on endangered cultural heritage, and publicly available online panels on repatriation—has greatly expanded our curricula. These measures have also made learning across borders more accessible for everyone. Continued development of such measures is not only beneficial but essential; the survival of both archaeological sites and museums depends on education to demonstrate the importance of cultural heritage, and the necessity of the institutions that protect it.

**Theme:** 5. Assembling archaeological theory and the archaeological sciences

**Organisers:** Rivollat, Maïté (PACEA, University of Bordeaux; MPI-SHH, Jena) - Szécsényi-Nagy, Anna (Institute of Archaeology Research Centre for the Humanities, Eötvös Loránd Research Network, Hungarian Academy of Sciences Centre of Excellence) - Hofmann, Daniela (Department of Archaeology, History, Cultural Studies and Religion, University of Bergen) - Cassidy, Lara (Molecular Population Genetics Lab, Trinity College Dublin) - Koncz, István (Institute of Archaeological Sciences, ELTE - Eötvös Loránd University, Budapest)

**Format:** Regular session

Over the last years, methodological advancements in ancient DNA allowed more specific studies, either at individual levels with high-covered genomes, or at group levels with extensive sampling. The evolution of the field makes now possible finer analysis at local scales, exploring in particular kinship and site organization. This increasing power of resolution offers new elements of analysis for the investigation of social structures, such as marital rules, female/male mobility, population size, consanguinity, networks at local or regional scales... As one can always object that biological kinship or affinities do not necessary demonstrate that the individuals either recognized this connection or bonded based on it, these elements open the discussion about the relationship between biological and social kinship. Developments of new analysis tools to explore these biological structures are actively in progress and will contribute to deeply improve our knowledge in this regard.

In parallel, the discussion now must include insights from social anthropology as well as archaeology to critically assess these new results in the light of human behavior. It also highlights our biases as modern societies and which we must question when coming to interpret social systems in ancient societies.

Many different perspectives can be brought together in this session to discuss this growing and exciting panel of ancient DNA data, with the aim to help building a critical and integrative research.

We welcome all researchers involved in genetics, archaeology, anthropology and social anthropology who want to contribute to an interdisciplinary discussion about biosocial archaeology. Contributions can address the following questions and research topics, for any time period:

- Case studies including analyses of social structures, kinship and site studies;
- New tools to explore genetic, archaeological or anthropological data in a social perspective;
- Theoretical discussions related to biosocial archaeology about interpretative choices, vocabulary, historical records and ethnoarchaeology.

ABSTRACTS:

1 MAKING KIN: THE ARCHAEOLOGY AND GENETICS OF HUMAN RELATIONSHIPS

**Abstract author(s):** Frieman, Catherine (Australian National University) - Bruck, Joanna (University College Dublin)

**Abstract format:** Oral

Kin-making is a key part of how humans structure their relations with each other, with their wider community and with the non-human world. Kin relations are constituted by shared values, shared experience, as well as by shared cultural or biological lineage. In recent years, archaeogenetics has offered us a startling level of clarity into biological relationships between individuals and groups of past people. At this crucial moment for our discipline, when archaeogenetic studies are being heralded as offering extraordinary insights into the social and political organisation of past communities, it is imperative that archaeologists retain a critical stance on the assumptions that so often underpin interpretations of archaeogenetic data.

In this paper, we argue that blood and biology are key elements of kin-making only in so far as they are contextualised and made sense of through social relations. The naturalisation of biological relatedness as the basis of kinship has its origins in the legacies of colonialism, which employed a particularly restrictive definition of kinship as a means of legitimating access to land and controlling the bodies of women and indigenous groups. Instead, taking as our inspiration the work of Indigenous scholars, we argue that the kinship produced through social relations and the kinship produced by genetic studies are not identical but can be complimentary.

Archaeology, with its focus on the material remains of the past, provides particular opportunities to examine how other forms of material and technological intervention (including ritual, exchange, and the sharing of food) facilitated the creation of kinship links not solely rooted in the human body. Here, we consider the extent to which the social salience of biological relationships identified through aDNA analysis can be addressed without imposing contemporary forms of familial structure and gender ideology onto the past.

2 INVESTIGATING NEOLITHIC SOCIAL STRUCTURES ON THE BASIS OF UNPRECEDENTEDLY LARGE FAMILY TREES FROM THE SITE GURGY “LES NOISATS” IN FRANCE

**Abstract author(s):** Rivollat, Maïté (University of Bordeaux, PACEA; Max Planck Institute for the Science of Human History, Department of Archaeogenetics, Jena) - Ringbauer, Harald (Max Planck Institute for the Science of Human History, Department of Archaeogenetics, Leipzig) - Childebayeva, Ainash (Max Planck Institute for the Science of Human History, Department of Archaeogenetics, Jena) - Le Roy, Mélie (Queen’s University Belfast, School of Natural and Built Environment, ArcPal) - Rey, Léonie (University of Bordeaux, PACEA) - Goude, Gwenaëlle (Aix Marseille University, CNRS, Ministry of Culture, LAMPEA) - Balter, Vincent (Ecole Normale Supérieure, Laboratoire de Géologie de Lyon) - Rottier, Stéphane - Deguilloux, Marie-France (University of Bordeaux, PACEA) - Haak, Wolfgang (Max Planck Institute for the Science of Human History, Department of Archaeogenetics, Jena)

**Abstract format:** Oral

The elucidation of kinship structure in past societies has been at the center of intra-group studies in archaeology and anthropology. However, the reconstruction of genetic relatedness in archaeological contexts has rarely been feasible. With the development of ancient DNA methods, it is now possible to obtain genome-wide data for multiple individuals from a single group, even in the presence of poor DNA preservation.

Here, we present new data from the Middle Neolithic French site of Gurgy “les Noisats”. Thanks to an extensive sampling and use of the 1240K capture array, we obtained genomic data for 94 out of 128 individuals. We reconstructed two large pedigrees, one of them spanning seven generations and connecting 62 individuals. These unprecedentedly large genealogies allowed us to look beyond the immediate genetic relatedness, and to explore the potential social structure of the group, its size, and its funerary and mobility practices.

We observed a strong patrilocal and patrilineal system with a single male lineage for the main family. The group practiced female exogamy, as no adult daughters were buried at the site (except for three females), and all mothers in the pedigree (except one) came from genetically-unrelated external groups, suggesting a wide regional network. Accompanying Strontium analyses confirm the non-local origin of adult females, but also reveal a non-local signature of the first-generation founders of the site. Biological relatedness reveals a spatial organization of the graveyard, showing chronological and nuclear family groupings that were not visible through archaeological elements. The seven-generations pedigree also allowed us to constrain the chronological range of the site use and led us to propose a narrower occupation phase.

In the case of Gurgy, biological relatedness opens a previously inaccessible window into the Neolithic and provides numerous insights into the social structure of this group.

3 ANCESTRY CHANGE AND KINSHIP ORGANISATION IN CHALCOLITHIC-EARLY BRONZE AGE BRITAIN: A CRITICAL ASSESSMENT OF MALE-DOMINATED MODELS

**Abstract author(s):** Bruck, Joanna (School of Archaeology, University College Dublin) - Booth, Tom (Francis Crick Institute)

**Abstract format:** Oral

Large-scale archaeogenetic studies of people from prehistoric Europe tend to be broad in scope and difficult to resolve with local archaeologies. Drawing together a critical anthropological perspective with the details of the archaeological record, we show how information provided in the supplementary information of Olalde et al. (2018) can provide new insights into patterns of ancestry change and genetic relatedness in the past. Olalde et al. identified a >90% shift in ancestry of people who lived in Britain during the Chalcolithic and Early Bronze Age. We assess suggestions that such changes were the result of swift and large-scale migration of ‘war bands’ of young men from continental Europe who practised exogamous marriage with women from local groups and introduced patriarchal forms of social organisation. While ancestry change was certainly influenced by movements of communities carrying novel ancestries into Britain, this was unlikely to have been a simple, rapid process, potentially taking up to 17 generations, during which time there is evidence for the synchronous persistence of groups largely descended from the Neolithic populations. Insofar as genetic relationships can be assumed to have had social meaning, identification of genetic relatives in cemeteries suggests paternal relationships were important, but there is substantial variability in how genetic ties were referenced and little evidence for strict patrilocality or female exogamy. It is evident, too, that relations with maternal kin were significant and that kinship was not solely predicated on genetic relatedness.

4 SALVAGING ADNA KINSHIP RESEARCH: A NECESSARY WAKE UP CALL AND REORIENTATION

**Abstract author(s):** Ensor, Bradley (Eastern Michigan University)

**Abstract format:** Oral

Archaeology, bioarchaeology, and genomics are challenging the dominance of ethnological approaches to prehistoric kinship. Unlike today’s kin term evolutionism, they have data that actually date to prehistory and can avoid dubious normative cultural models interpreted through discredited 19th century phylogenetics or 1960s neoevolutionism. Though largely ignored or misunderstood in Europe, archaeological kinship analysis is the most developed and can detect intra- and inter-community variation and change. Bioarchaeological kinship analysis - using strontium isotope ratios or phenotypic traits - needs more informed interpretive models. From a social anthropological perspective, European genomic research has the most impoverished understanding of kinship, is ethnocentrically obsessed with uninformative nuclear family relations, and some is alarmingly mired in pre-WWII essentialism - particularly

disturbing in an era of reemerging racist nationalism. At stake is whether genomics will become relevant to kinship research or serve as a precautionary tale as it is currently headed. Because kinship is always a social construction, aDNA researchers need models for interpreting how different kinds of corporate kin groups socially distribute biological relatedness within and across settlements and cemeteries. This paper illustrates how common kinship practices manipulate intra- and intergroup/cemetery biological compositions and re-analyzes published aDNA, strontium, and archaeological data from Central European Neolithic sites (patrilocality is not supported). Far from the sensationalist image of aDNA providing a definitive source, different kinship practices produce difficult to distinguish aDNA distribution patterns - a problem compounded by inappropriate cemetery sampling. However, aDNA results can be clarified when combined with strontium isotope ratios for individual life histories. In turn, archaeological kinship analyses can further clarify those results. Ancient DNA can potentially contribute productively to prehistoric kinship research but only if scholars familiarize themselves with the subject, adopt informed interpretive models and appropriate sampling, and combine their data with other sources.

5 **EARLY BRONZE AGE FAMILIES IN THE NORTHWESTERN CARPATHIAN BASIN**

**Abstract author(s):** Szecsenyi-Nagy, Anna (Institute of Archaeogenomics, Research Centre for the Humanities, Eötvös Loránd Research Network) - Šefčáková, Alena (Department of Anthropology, Slovak National Museum–Natural History Museum) - Olalde, Inigo (Department of Genetics, University Pompeu Fabra) - Ringbauer, Harald (Department of Archaeogenetics, MPI EVA, Leipzig) - Bartík, Juraj - Farkaš, Zdeněk - Jelínek, Pavol (Slovak National Museum–Archaeological Museum) - Daňová, Klaudia (Archaeological Institute of the Slovak Academy of Sciences) - Pinhasi, Ron (Department of Evolutionary Anthropology, University of Vienna) - Reich, David (Department of Genetics, Harvard Medical School; Department of Human Evolutionary Biology, Harvard University)

**Abstract format:** Oral

Fine-scale ancient DNA analyses provide not only insights to prehistoric demographic processes, but also a deeper understanding of the studied communities’ structure and organization. Here we present intensively sampled Early Bronze Age graveyards (assigned to the Nitra and Ůnětice cultures) from the north-west part of the Carpathian Basin, and compare the new genomic data with anthropological and archaeological records and theories. Several families are reconstructed based on the genome-wide capture data, and attempts on reconstructing distant relatedness is also presented. A comprehensive analyses of the paternal and maternal lineages, together with the autosomal DNA results enable to reformulate the current knowledge about the social system of the Nitra (Nitrianska) culture’s population, that culture was disseminated in present-day southwest Slovakia and southern Moravia. The Nitra culture followed epi-Corded Ware traditions in many ways, and most of the burials showed emphasis on highlighting the gender and social status of the buried individuals. The homogeneity of the male lineages of the Nitra culture’s population, the detected distinct ancestry components and the comparison of the male and female admixture signals all contribute to a new way of understanding of the social changes at the dawn of the Bronze Age in East-Central Europe.

6 **HOME IS WHERE THE HEARTH IS: EXPLORING SEX BIAS IN GENETICALLY-ATTESTED MIGRATIONS IN PREHISTORIC EUROPE**

**Abstract author(s):** Büster, Lindsey - Armit, Ian (University of York)

**Abstract format:** Oral

Recent large-scale ancient DNA studies have transformed our understandings of past population dynamics and, coupled with multi-proxy approaches such as stable isotope analysis, provide us with new insights into movement and mobility at a number of scales. Particularly striking has been the significance of population movement as a vector of cultural change. For many, this realisation carries uncomfortable echoes of early twentieth century archaeology, when migration, often implicitly presented as violent colonisation by a dominant group, was too easily invoked as the primary driver of change. Migration, however, as we can see from the world today, takes many forms, and can be a long-term process rather than a single event. Movement can be voluntary or forced, and is often undertaken by desperate or marginalised individuals and groups. Migratory pressures are also typically bound up with issues of age, class and gender. Indeed, recent aDNA analyses have demonstrated the major role of female mobility in Neolithic and Bronze Age societies. Traditional interpretations of prehistoric mobility have tended to focus on long-distance, male-dominated networks, but—drawing on the results of recent work on the Middle–Late Bronze Age in southern Britain—this paper argues that female mobility was crucial in instigating significant changes in language and culture. While the large-scale movement of women does not necessarily negate the presence of male-dominated power structures, it forces us to consider the lived realities of these migrants and the ways in which their own agency transformed their host communities from the inside out.

7 **SOCIAL BELONGING BETWEEN GENES AND PRACTICES**

**Abstract author(s):** Stockhammer, Philipp (LMU Munich; MPI Jena)

**Abstract format:** Oral

Recent breakthroughs in archaeogenetics have not only produced ground-breaking new insights into the deep past, but also raised the risk of reinforcing biological determinism in the constitution of social structure. Whereas New Kinship Studies have demonstrated the usual complexity of “feeling related”, the challenge of tracing such “feelings” in the archaeological record has instigated us to emphasize the notion of “biologically related”. However, we need to take into account that past human world views were shaped by completely different assumptions about being human in the world and that present-day world views shaped by current scientific

knowledge present only one way of understanding belonging. In my paper, I will first present my approach to linking scientific and archaeological datasets in order to understand the dynamics of social belonging out of the dialogue of genes and social practices like gender, age, mobility, nutrition and status. Subsequently, I will discuss case studies from Central Europe and the Eastern Mediterranean, where bioarchaeological datasets have recently enabled fascinating new insights into past social structures. Finally, I aim to show how we might use these datasets to take a further step towards the understanding of past social belonging and consequently past world views.

8 **GENETIC INSIGHTS INTO KINSHIP AND SOCIAL STRUCTURE OF AN IRON AGE COMMUNITY FROM TUVA, SOUTHERN SIBERIA**

**Abstract author(s):** Keller, Marcel (Institute of Genomics, University of Tartu) - Caspari, Gino (Department of Archaeology, University of Sydney; Institute of Archaeological Sciences, University of Bern) - Milella, Marco (Department of Physical Anthropology, Institute of Forensic Medicine, University of Bern) - Sadykov, Timur (Institute for the History of Material Culture, Russian Academy of Sciences, St. Petersburg) - Blochin, Jegor (Institute for the History of Material Culture, Russian Academy of Sciences, St. Petersburg) - Szidat, Sönke (Department of Chemistry and Biochemistry, University of Bern; Oeschger Centre for Climate Change Research - OCCR, University of Bern) - Saag, Lehti (Institute of Genomics, University of Tartu) - Kivisild, Toomas (Department of Human Genetics, KU Leuven; Institute of Genomics, University of Tartu) - Lösch, Sandra (Department of Physical Anthropology, Institute of Forensic Medicine, University of Bern) - Scheib, Christiana (Institute of Genomics, University of Tartu; St John’s College, University of Cambridge)

**Abstract format:** Oral

The site of Tunnug1 (Republic of Tuva, Southern Siberia) is prominent for its ‘Scythian’ kurgan (9th c. BCE) but includes also significantly younger features such as a funerary complex of the Kokel culture (2nd–5th c. CE). The skeletal material of this cemetery is remarkable for the high incidence rate of perimortem trauma due to interpersonal violence interpreted as signs of warfare, executions or rituals. However, the single and multiple graves including grave goods indicate a careful funerary treatment, and radiocarbon dating suggests usage of this cemetery over several centuries.

In this case study, we aim to explore the social structure and kinship of this population through ancient DNA analyses on more than 50 individuals. Genome-wide sequencing data revealed a heterogeneous genetic background of these individuals forming a cline with different proportions of Western hunter-gatherer and Han-like ancestry, reflecting the high mobility of this nomadic steppe culture. However, first- and second-degree relationships among the individuals support the interpretation as one or multiple social communities.

Dating to the period following the fall of the Xiongnu Empire, this site offers valuable insights into the social organization of a ‘Hunno-Sarmatian’ population in the face of political instability.

9 **GENETIC METHODS IN ARCHAEOLOGICAL RESEARCH (FUNDED BY GOVERNMENT GRANT NO. 075-15-2019-1879)**

**Abstract author(s):** Ochir-Goryaeva, Maria (Kalmyk Research Center Russian Academy of Sciences)

**Abstract format:** Oral

The introduction of genetic methods in archaeological research, has brought the studies of blood relations and social hierarchies of archeological societies to a new level. The results obtained by these methods have often the force of irrefutable facts. However, it may be quite useful to remember that cultural and historical interpretations are impossible without detailed analyses and examinations of archaeological sites, the only sources of information about prehistoric individuals and entire ethno-cultural communities.

To illustrate, the genetic analysis of twenty individuals from five burial mounds of the Scythian era located in the Sayan Highlands indicated that thirteen of them were first-degree relatives [Mary, et al., 2020]. In another work the examination of a Hunnic necropolis in Mongolia has allowed to establish that it comprised the representatives of five generations of two family clans buried in the same necropolis [Keyser et al., 2020]. Unfortunately, these and a number of similar articles discuss only the results of the work of geneticists. They shed no light on the planigraphy of the kurgan groups under study or on the analysis of their burial structures; there is no data concerning the chronology of the burials. When archaeology with its rich experience in the field is left neglected, the results of geneticists may appear less convincing or even doubtful. Archaeology has a whole arsenal of reliable methods and approaches, which can be illustrated by excellent examples in the studies of Scythian royal mounds [Aleksseev 1991; Mozolevsky, Polin 2005]. Of relevance is also the method of spatial analysis developed by the present author; this has proved to be quite effective in establishing social hierarchies, when the depth of graves and their location, with respect to each other and the space organization inside the mounds, are taken into special consideration [Ochir-Goryaeva, 2018].

KIN AND POWER IN EARLY CELTIC COMMUNITIES OF SOUTHWESTERN GERMANY

**Abstract author(s):** Gretzinger, Joscha - Mötsch, Angela (Max Planck Institute for the Science of Human History) - Schmitt, Felicitas - Francken, Michael (State Office for Cultural Heritage Baden-Wuerttemberg) - Rathmann, Hannes (Institute for Archaeological Sciences, Eberhard Karls University, Tübingen; Senckenberg Centre for Human Evolution and Palaeoenvironment, Tübingen) - Wieland, Günther (State Office for Cultural Heritage Baden-Wuerttemberg) - Harvati, Katerina (Institute for Archaeological Sciences, Eberhard Karls University, Tübingen; Senckenberg Centre for Human Evolution and Palaeoenvironment, Tübingen; DFG Centre for Advanced Studies 'Words, Bones, Genes, Tools: Tracking Linguistic, Cultural and Biological Trajectories of the Human Past', Tübingen) - Schier, Wolfram (Institute for Prehistoric Archaeology, Free University Berlin) - Krausse, Dirk (State Office for Cultural Heritage Baden-Wuerttemberg; Institute of Prehistory, Early History and Medieval Archaeology, Eberhard Karls University, Tübingen) - Krause, Johannes - Schiffels, Stephan (Max Planck Institute for the Science of Human History; Max Planck Institute for Evolutionary Anthropology)

**Abstract format:** Oral

The European Iron Age is characterised by the two key archaeological cultures Hallstatt and La Tène in a large region to the north of the Alps, which are broadly associated with ‘Celts’. While this term does not serve as an accurate description or grouping of a homogenous people or ethnic group, it highlights the close connection between a specific archaeological horizon, hypothesised linguistic affiliations (Celtic languages), and historical sources. The pan-European patterns and linguistic evidence for cultural connections during this time are complex and encompass a huge region from the Iberian Peninsula throughout Central Europe and as far east as Anatolia (during the 3rd century BC). However, during the earlier phase of the Iron Age (800 – 450 BC, Hallstatt C and D), a core region in Southwestern Germany and Eastern France, the ‘West-Hallstattkreis’, stands out in its archaeological importance, as highlighted by the emergence of rich and unprecedented ‘princely burials’, typically associated with the early Celts. Up to the present-day, the identity of these buried elites and the political power they represented remain controversial, with suggestions including chieftains, spiritual leaders, or even kings. Here, we describe and analyse the first genome-wide data from Southwest Germany dating to the late Hallstatt period. By reconstructing the genetic profiles of more than 20 individuals from this early Celtic population in Germany, we gain insights into familial relationships, transregional connections, system of rule, and the substantial population movements postdating the Iron Age in the region.

ANCIENT GENOMES REVEAL SOCIAL AND GEOGRAPHIC STRUCTURING OF THE POPULATION IN CARPATHIAN BASIN AT THE TIME OF THE AVAR EMPIRE

**Abstract author(s):** Gneccchi Ruscone, Guido Alberto (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Leipzig) - Szécsényi-Nagy, Anna (Institute of Archaeology, Research Centre for the Humanities, Eötvös Loránd Research Network) - Koncz, István (Institute of Archaeological Sciences, Eötvös Loránd University) - Csiky, Gergely (Institute of Archaeology, Research Centre for the Humanities, Eötvös Loránd Research Network) - Rácz, Zsófia (Institute of Archaeological Sciences, Eötvös Loránd University) - Reich, David (Department of Genetics, Harvard Medical Schoo; Department of Human Evolutionary Biology, Cambridge; Broad Institute of Harvard and MIT; Howard Hughes Medical Institute, Harvard Medical School) - Vida, Tivadar (Institute of Archaeology, Research Centre for the Humanities, Eötvös Loránd Research Network; Institute of Archaeological Sciences, Eötvös Loránd University) - Hofmanová, Zuzana (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Leipzig; Department of Archaeology and Museology, Faculty of Arts, Masaryk University) - Jeong, Choongwon (School of Biological Sciences, Seoul National University) - Krause, Johannes (Department of Archaeogenetics, Max Planck Institute for Evolutionary Anthropology, Leipzig)

**Abstract format:** Oral

According to historical records, the Avars settled the Carpathian Basin in 568 CE, where they established the Avar “Qaganate” that lasted over 250 years, exerting a major influence in shaping the history Early Medieval Europe. Archaeological records of their material culture testify Inner or Central Asian origin of certain elements, but intensive contacts with the Byzantine Empire and the Eastern European steppe are also detected. Despite the rich archeological record and various historical sources, the genesis of the Avars and the social and political composition of their nomadic empire is still highly controversial and debated among scholars. The Qaganate unified people of different origin, and incorporated them to the empire on various levels. Local elites emerged that kept distinct traditions, but autochthon people probably also admixed with the newcomers.

Here we analyze new genome-wide data of 66 Early Medieval period individuals from present-day Hungary. Part of them were uncovered from Avar period elite burials located in the Danube-Tisza region, the primary power center of the Avar empire. The remaining were retrieved from different archeological contexts in the immediate surrounding areas from the IV-VIII. centuries. Our results reveal striking patterns of genetic structuring, mirroring geography and social stratification of the both culturally and genetically heterogeneous population of the Avar empire.

MATERNAL LINEAGES FROM 10-11TH CENTURY COMMONER CEMETERIES OF THE CARPATHIAN BASIN

**Abstract author(s):** Maár, Kitty (Department of Genetics; University of Szeged) - Varga, Gergely - Kovács, Bence (Department of Archaeogenetics; Institute of Hungarian Research) - Schütz, Oszkár (Department of Genetics; University of Szeged) - Tihanyi, Balázs (Department of Archaeogenetics; Institute of Hungarian Research; Department of Biological Anthropology; University of Szeged) - Maróti, Zoltán (Department of Pediatrics and Pediatric Health Center; University of Szeged; Department of Archaeogenetics; Institute of Hungarian Research) - Nagy, István (SeqOmics Biotechnology Ltd.; Institute of Biochemistry; Biological Research Centre, Szeged) - Raskó, István (Institute of Genetics; Biological Research Centre, Szeged) - Neparácski, Endre (Department of Archaeogenetics; Institute of Hungarian Research; Department of Genetics; University of Szeged) - Török, Tibor (Department of Genetics; University of Szeged; Department of Archaeogenetics; Institute of Hungarian Research)

**Abstract format:** Oral

The conquer of the Carpathian Basin by the Hungarian tribes in the 9th century played a fundamental role in the history of Hungary, but the origin of the 10-11th century Hungarian people is still poorly understood. Based on the burial characteristics an elite social stratum can be discriminated from the major, commoner layer of the Conquer Period, but nothing is known about the genealogical relationship of these two groups. Genetic studies so far mostly concentrated on the investigation of the elite, therefore we set out to examine the genetic structure of the commoners, in order to be able to compare the two groups. We determined the complete mitochondrial genome sequences of 202 remains, most of them belonged to the plebeian people of the 10-11th century Carpathian Basin. We detected considerable (12%) Asian phylogeographic ancestry among the investigated individuals, which was considerably smaller than that in the elite (30%). Population genetic analyses revealed significant differences between the two groups, and mapped the commoners to ancient European populations, while the elite was mapped much closer to Asian groups. However shared sub-haplogroups between the elite and commoner layers indicated admixture between them, which happened in both directions, but by the 11th century this was not yet enough for genetic equalization.

THE LATE-ANTIQUÉ FUNERARY COMPLEX OF ITTENHEIM (ALSACE, BAS-RHIN). RE-READING OF ARCHAEO-ANTHROPOLOGICAL DATA AT THE DAWN OF GENOMICS

**Abstract author(s):** Pruvost, Melanie - Mendisco, Fanny (Université de Bordeaux, CNRS, UMR5199 PACEA) - Barrand-Emam, Hélène (ANTEA-Archéologie, UMR 7044) - Chenal, Fanny (Inrap Grand Est, UMR 7044)

**Abstract format:** Oral

The Ittenheim site “Lotissement du stade” (Bas-Rhin, France) delivered a small Late Antiquity community burial complex consisting of 23 burials, occupied over a short period of time from AD 350 to 430-450. Confined within a small space of 225 m², the funerary ensemble seems to be organised in small groups of tombs separated by empty areas and a few loosely arranged graves. A study of the age and sex composition of the population showed that the mortality profile was compatible with that of natural mortality, with the exception of the total absence of individuals under one year of age.

The way in which burials are laid out in small groups of graves raises questions about the type of recruitment with possible kinship ties (biological or social) between these different individuals.

In order to verify these working hypotheses, a palaeogenomic study was carried out over the entire necropolis. Thanks to the excellent preservation of DNA on this site, it was possible to obtain the complete genome of more than 90% of the individuals. These results enabled us to find family links between individuals within the different groups and partially confirm the hypotheses of family regroupings established by the archaeological studies. However, these analyses also raised new questions, particularly about the origin of these individuals.

The relatively small number of burials on the Ittenheim site and the favourable taphonomic conditions have enabled an almost exhaustive palaeogenetic analysis of this site, making it an exemplary site for comparing genomic and archaeological data at different levels : management of the burial space, geographical origin of the individuals and also the variability of funeral practices within the same family group, chronology of the site...

INVESTIGATING KINSHIP PRACTICES THROUGH DENSE SPATIAL AND TEMPORAL SAMPLING OF 5-6TH CENTURY CEMETERIES IN PANNONIA

**Abstract author(s):** Koncz, István (Eötvös Loránd University, Institute of Archaeological Sciences) - Vyas, Deven (Department of Ecology and Evolution, Stony Brook University) - Vida, Tivadar (Institute of Archaeological Sciences, Eötvös Loránd University; Institute of Archaeology, Research Centre for the Humanities, Eötvös Loránd Research Network) - Mende, Balázs (Institute of Archaeology, Research Centre for the Humanities, Eötvös Loránd Research Network) - Krause, Johannes (Department of Archaeogenetics, Max Planck Institute for the Science of Human History; Institute for Archaeological Sciences Archaeo- and Palaeogenetics, University of Tübingen) - Kay, Janet (Department of Art & Archaeology, Princeton University) - Pohl, Walter (Institute for Medieval Research, Austrian Academy of Sciences) - Veeramah, Krishna (Department of Ecology and Evolution, Stony Brook University) - Geary, Patrick (School of Historical Studies, Institute for Advanced Study, Princeton)

**Abstract format:** Oral

When used in conjunction with archaeology, paleogenomics can be a powerful tool to better understand human history, demography and with the sampling of whole sites it could also provide insights to the processes involved in the formation of communities

and social structures. This is especially interesting in the Middle Danube Region as very few parts of Europe witnessed so many population shifts in a few centuries as this area during the early Medieval period. After the decline of the Roman rule in Pannonia (433 AD) came a time of political instability. From the last decades of the 4th century onward until the arrival of the Avars in the late 6th century, population groups arrived continuously into the Carpathian Basin. This political instability led to the emergence of a mosaic-like cultural landscape with small burial sites consisting of around 20-50 graves. In our study, we analyze three cemeteries near the southern shore of Lake Balaton (in present-day Hungary) from the 5th and 6th centuries. We present new findings from two nearby late-5th-century cemeteries named Hács and Balatonszemes and compare them to the mid-6th-century cemetery of Szólád published by Amorim et al. (2018). We use principal component analyses and genetic clustering analyses to characterize the genetic ancestry of the 25 individuals and estimate levels of kinship between them. We analyze these results alongside the archaeological record of the sites to investigate how differences in ancestry and kinship are reflected within the layouts of the cemeteries and whether these are similar from cemetery to cemetery. Furthermore, we also use analyses of identity-by-descent (IBD) tracts in the genomes to test whether there is population continuity between the late fifth century Hács and Balatonszemes with sixth century Szólád or whether there is evidence of the continuous immigration attested by the written sources.

15 **INVESTIGATING KINDREDS AND WAVES OF MIGRATION IN 6-8TH CENTURY NORTHERN ITALY THROUGH ARCHAEOLOGICAL AND PALEOGENOMIC ANALYSES**

**Abstract author(s):** Koncz, István (Institute of Archaeological Sciences, Eötvös Loránd University) - Tian, Yijie (Department of Ecology and Evolution, Stony Brook University) - Modi, Alessandra (Dipartimento di Biologia, Università degli Studi di Firenze) - Giostra, Caterina (Dipartimento di Storia, Archeologia e Storia dell'Arte, Università cattolica del Sacro Cuore) - Kay, Janet (Department of Art & Archaeology, Princeton University) - Bedini, Elena (Dipartimento di Storia, Archeologia e Storia dell'Arte, Università cattolica del Sacro Cuore) - Pohl, Walter (Institute for Medieval Research, Austrian Academy of Sciences) - Caramelli, David (Dipartimento di Biologia, Università degli Studi di Firenze) - Krause, Johannes (Department of Archaeogenetics, Max Planck Institute for the Science of Human History; Institute for Archaeological Sciences Archaeo- and Palaeogenetics, University of Tübingen) - Geary, Patrick (School of Historical Studies, Institute for Advanced Study)

**Abstract format:** Oral

The Langobard conquest of Italy is one of the most well documented migrations in early medieval Europe. Collegno, near Turin – founded around the turn of the 6th-7th centuries and remained in use till the 8th century – is among the most important burials sites dated to the beginning of the Langobard occupation. Previous study from the Veeramah Lab showed that the community was organized around biological kinship with multiple kindreds. The former study focused on the first phase of the site, but additional sampling from its later phases allows us a more comprehensive study of this cemetery. While a large part of the earliest period individuals had more ancestry associated with contemporary northern Europeans, the later period is marked by the arrival of a new genetic ancestry. This pattern suggested that there might have been multiple different groups of people that arrived and settled in this region gradually within a period of time. We were able to find new kindreds and complement the old ones with individuals from the later phases. Integrating paleogenomic results with archaeological data we found correlation between burial customs and kindred groups and we identified patterns that suggest the community was indeed organised around biological relatedness, but rather than around the wider kinship, the focus was on the core families.

16 **USING ADNA AS PART OF A MULTI-PROXY APPROACH TO UNDERSTAND BIOLOGICAL AND SOCIAL KINSHIP OF UNUSUAL BURIALS FROM PORTMAHOMACK (SCOTLAND)**

**Abstract author(s):** Fischer, Claire-Elise (Department of Archaeology, University of York) - Olalde, Iñigo (Institute of Evolutionary Biology, CSIC - Universitat Pompeu Fabra; Department of Genetics, Harvard Medical School) - Reich, David (Department of Human Evolutionary 46 Biology, Harvard University; Broad Institute of MIT and Harvard; Department of Genetics, Harvard Medical School, Boston; Howard Hughes Medical Institute, Boston) - Armit, Ian - Carver, Martin (Department of Archaeology, University of York) - Spall, Cecily (FAS HERITAGE)

**Abstract format:** Oral

The Tarbat Discovery Programme is best known for the excavation of an 8th-century Pictish monastic settlement which lay around and beneath the Church of St Colman, Portmahomack, Easter Ross, Scotland. The results of the 20-year research programme also identified exceptional archaeology belong to a later medieval settlement of the 13th to 16th centuries. Evidence for housing and craft-working was excavated, as well as over 80 medieval burials from the nave (Carver et al. 2016)

This paper presents the results of a recent scientific enquiry into a group of highly unusual burials, including a grave that contained six skulls. It was located in the central part of the nave of the church to accommodate an oak coffin containing the body of an adult male, bearing signs of perimortem sharp force injuries. This individual was buried with a group of four skulls around his head. Some-time later, the grave was reopened for the burial of a second man, an event accompanied by the rearrangement of the skull of the grave’s earlier occupant. These highly unusual burials have been the subject of a multi-proxy approach, combining detailed osteological study, radiocarbon dating including Bayesian analysis, multi-isotope analysis, facial reconstruction and ancient DNA analysis. For the aDNA, nine samples were targeted from which eight yielded genome-wide data.

Results highlight that seven of the individuals are males, with only one female was identified. They also show a high diversity of mitochondrial DNA and a relatively low diversity of the Y chromosome. Kinship analysis performed on these samples indicates a family composed of five individuals, including a woman.

Altogether, the data allows different scenarios for this family to be constructed and provides insight into Scottish clan organisation.

A. **SURVIVAL OF ADNA IN TOOTH AND BONE SAMPLES FROM IRON AGE (7TH – 12TH CENTURIES AD) BURIALS IN LATVIA**

**Abstract author(s):** Ranka, Renate - Ķimsis, Jānis - Pokšāne, Alise (Latvian Biomedical Research and Study Centre) - Pētersone-Gordina, Elīna - Vilcāne, Antonija (Institute of Latvian History, University of Latvia) - Kazarina, Alisa (Latvian Biomedical Research and Study Centre) - Gerhards, Guntis (Institute of Latvian History, University of Latvia)

**Abstract format:** Poster

Ancient DNA (aDNA) studies offer new possibilities for the in-depth investigation of ancient social structures at local and regional scales. Human aDNA studies have helped to decode the human history on the Eurasian continent. Present-day Latvia is situated in north-eastern Europe with a coastline along the Baltic Sea. During the Iron Age the local inhabitants began to form distinct ethnic and regional identities. The productive farms continued to develop, and crafts and trade became increasingly important. Studies of historical genomes and metagenomes may help to explore many different perspectives, in particular kinship, female/male mobility, funeral ritual practice, and life experiences. However, endogenous DNA preservation in human skeletons is crucial for aDNA studies.

Here, we examined DNA preservation within tooth and bone samples from two Iron Age cemeteries in Latvia: Lejasbīteni (Vidzeme region), and Cunkani–Drengeri (Zemgale region) (7th – 11th centuries AD). The DNA extraction was performed according to a modified version of the protocol of Keyser-Tracqui and Ludes, 2005. Metagenomics shotgun libraries were sequenced using Illumina technologies. Raw-read sequencing data were processed using the EAGER pipeline for aDNA sequencing data. For microbial DNA analysis, read files were analyzed using MALT 0.5.0. The results indicated that human DNA proportion in bone samples was less than 10%. Higher proportion of human DNA was recovered from the petrous pyramid and well-preserved tooth samples, while mitochondrial DNA yields varied greatly between individual specimens. The presence of oral microbiome signature was detected in archaeological tooth samples indicating the preservation of ancient microbial DNA. Overall, we were able to access the endogenous aDNA in archaeological tooth and bone samples. The availability of aDNA data will be highly useful for investigation of the demographic history and social structures in Iron Age Latvia.

469 **COAST LAND CONTACTS – THE SOUTHERN BALTIC AREA IN EARLY HISTORICAL TIMES (1 – 600 AD)**

**Theme:** 7. From global to local: Baltic-Pontic studies

**Organisers:** Voss, Hans-Ulrich (Römisch-Germanische Kommission, Frankfurt am Main) - Schuster, Jan (Instytut Archeologii Uniwersytetu Łódzkiego) - Schmidt, Jens-Peter (Landesamt für Kultur und Denkmalpflege Mecklenburg-Vorpommern, Landesarchäologie, Schwerin)

**Format:** Regular session

The southern Baltic Sea coastal area is a supra-regional contact zone in all epochs, including the Roman Iron Age and the Late Antiquity. A special feature is the fact that the communications lead on the one hand by sea to Scandinavia, on the other hand by land to Western and Central Europe as well as the Eastern Baltic States. They connected the drainage basins of important European rivers - the Elbe, the Oder, the Vistula up to the Düna (Daugava) and the Neva. During the period under consideration here, the archaeological characteristics of these greater areas are very different. At present, countless metal detector finds enrich our knowledge of the contacts between North and South and East and West that can be made with components of costume and jewelry, but also with personal equipment and armament. The session will discuss how research reacts to the associated challenges. What new findings does the current flood of base and precious metal finds provide on questions of the availability of the raw material non-ferrous metal, the development of style and costume provinces, as well as the analysis and interpretation of regional and supra-regional contacts? Are there any research opinions that are confirmed by new discoveries? Does this have any consequences for the description, e.g. the archaeological phenomena known as the “Elbgermanen”, Wielbark and Dollkheim-Kovrovo cultures, and if so, which ones?

**ABSTRACTS:**

1 **ARCHAEOLOGICAL DATA ON CULTURAL CONTACTS IN THE SOUTHERN BALTIC COASTAL AREA FROM A PERSPECTIVE OF RESEARCH**

**Abstract author(s):** Voss, Hans-Ulrich (RGK - Romano-Germanic Commission DAI)

**Abstract format:** Oral

It is one of the generalities of our discipline that coasts and seas are natural spaces of transport. Maritime trading places, harbours and landing sites, which have recently been of particular interest to research, are just as eloquent a testimony to this as the remains of boats and ships. Due to the so-called “night jumping method”, crossing the Baltic Sea in prehistoric and early historic times was

possible even without a permanent view of coasts or navigational aids such as the compass. In this lecture, however, the focus is not on the north-south/south-north connection to and from Scandinavia, but on the land connection along the southern Baltic Sea coast. Based on Hans Jürgen Egger’s studies on Roman “import” from the first half of the 20th century, the find spectra of Roman material goods are compared with those of non-Roman origin. Against this background, the archaeological evidence for connections between population groups of different cultural character will be discussed in a diachronic comparison, and the interpretations attached to them – the mobility of persons or groups of persons, marriage relations and networks of social groups, trade – questioned against the background of the recent increase in source material, especially metal finds.

One example are the different distribution patterns of Roman bronze vessels in that part of the study area in the northern Elbe and Oder-Vistula regions, which contrast with the occurrence of indigenous products such as pottery, and brooches.

A good example of the picture, which has changed considerably in recent years due to new finds, is the “Thuringian” influence from Central Germany, which can now be identified west of the lower river Oder in the second half of the 5th century and traces of which reach as far as the areas east of the lower river Vistula.

## 2 “PIZZA CONNECTION” – MOBILITY OF MEN AND OBJECTS BETWEEN SICILY AND THE NORTH

**Abstract author(s):** Rasbach, Gabriele (RGK - Romano-Germanic Commission DAI)

**Abstract format:** Oral

The period between the 1st century BC and the 1st century AD is an age of constant warfare in the western Mediterranean between Carthage and Rome, socially motivated struggles, wars for supremacy in Rome and the imperial expansion of Rome to the north. The lecture shows the mobility of people and metal objects (brooches and coins) in this period.

Starting point is the Hellenistic-Roman settlement on Monte Iato in the hinterland of Sicily, which has been studied for over 40 years by archaeologists from the University of Zurich. Unlike in Central Europe, the chronology of the Mediterranean region is based on ceramics. Metal finds, with exception of coins, have so far played a subordinate role in the chronological classification of layers and the cultural-historical classification of a site. The finds that are focused here are fibulae and military equipment. Approaching individuals on the basis of material culture is not an easy undertaking. Nevertheless, an attempt will be made to use this material to approach the actors and groups who fought for supremacy in the western Mediterranean during the centuries BC.

The metal finds include brooches that are also relevant to the north, such as 25 Jezerine brooches, 20 pieces of the Alesia type and a Gorica brooch. The fibulae spectrum of the centuries around the birth of Christ is completed by various forms of Aucissa fibulae; the youngest fibula - an Early Imperial Lunula fibula - is a unique piece.

The distribution of these fibula types and the quantity of pieces in Sicily, especially at the sites of Monte Iato and Morgantina, raises questions about the historical events, the groups involved in them and their mobility, and offers the possibility of taking a comparative look at the chronologies south and north of the Alps.

## 3 “BARBARIAN” FIBULAE (ALMGREN GROUP V) AND THE FORMATION OF A REGIONAL MODEL OF FEMALE DRESS IN THE SOUTHEAST BALTIC

**Abstract author(s):** Khomiakova, Olga (Institute of Archaeology of RAS, Moscow)

**Abstract format:** Oral

Fibulae as details of dress appeared in the Southeast Baltic with the beginning of the formation of archaeological cultures of the Roman period and the activation of the Amber Route in the 1st century AD. Already from the earliest phase (B1/B2) in the dress of the Sambian-Natangian culture (SNC), associated with the Aestians of Tacitus, both Provincial-Roman and “barbarian” “comb” fibulae (Kopfkammfibeln) appeared.

The report presents a possible reconstruction of the process of the formation of a regional model of female dress in the Southeast Baltic in the first centuries AD. The study is based on a review of the SNC complexes of the 1st – 2nd centuries with “barbarian” elements, the leading role among which is occupied by fibulae of group V of O. Almgren. The traditions of production of Northern-European “barbarian” fibulas influenced the emergence in the Baltic cultures of their own fibula set, jewelry style and dress in general.

The dress model of the “Middle Danube look”, fully accepted by the SNC population at the boundary of the B1/B2 phases, was quickly (during the life of one or two generations) eroded under the influence from the territories of neighboring cultures. At the end of the 1st - the beginning of the 2nd century the dress was only supplemented by individual ornaments, the origin of which was not associated with the Provincial-Roman style. Then by the middle of the 2nd century it was completely formed by a set of elements of the “barbarian” tradition. Appeared in the middle of the 2nd century on the Kaliningrad Peninsula (Sambia), in a contact zone with East Germanic cultures, the model of female dress influenced the dressing of the rest of the Baltic and more eastern territories of the western part of the forest zone of Eastern Europe.

## 4 ABOUT BALTIC CONNECTIONS OF THE LATE ROMAN SHIELD BOSS FROM HERPÁLY (H)

**Abstract author(s):** Heinrich-Tamaska, Orsolya Mariann (-) - Masek, Zsófia (-) - Becker, Matthias (-) - Voß, Hans-Ulrich (-)

**Abstract format:** Oral

The origin of the Late Roman shield boss with horizontal grip from Herpály has been the subject of several studies, which have largely concentrated on stylistic and formal criteria. The shield was discovered in the mid-nineteenth century in a barrow cemetery from the Sarmatian Period in Hungary. The analysis of its decoration elements reveals that the shield’s design combines both Roman and Nordic-Germanic elements and constitutes an individual stylistic departure in the 3rd century AD in the eastern Carpathian Basin.

This contribution also presents the results of recent light microscopic and XRF analyses of the artefact. The study was intended to reconstruct the shield’s manufacturing process, its workmanship and gilding of the individual mounts made of pressed sheet metal, and to identify the composition of its alloy as well as repairs and unusual technical solutions. Its results are then discussed within the context of other finds of shield bosses with sheet metal mounts of the 3rd to early 5th century AD (e.g. from Gommern, Vermand and Illerup) to obtain new information concerning the different workshop traditions related to the Herpály shield boss.

## 5 BOOTY OR PAY? FINDS OF ROMAN PROVINCIAL COINS ON THE SAMBIAN TERRITORY

**Abstract author(s):** Myzgin, Kyrilo (Faculty of Archaeology, University of Warsaw) - Konstantin, Skvorcov (Institute of Archaeology, Russian Academy of Science)

**Abstract format:** Oral
